The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = -\frac{1}{4x^2}$$

Since the $\gcd(s,t)=1$. This gives $b=-\frac{1}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0\\
\alpha_\infty^{+} &= \frac{1}{2}+\sqrt{1+4b}=\frac{1}{2}\\
\alpha_\infty^{-} &= \frac{1}{2}-\sqrt{1+4b}=\frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r=-\frac{1}{4x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-}=\frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^{-}-\left(\alpha_{c_1}^{-}\right)\\
&= \frac{1}{2}-\left(\frac{1}{2}\right)\\
&= 0
\end{aligned}
$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$
\omega=\sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c+\frac{\alpha_c^{s(c)}}{x-c}\right)+s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1}+\frac{\alpha_{c_1}^{-}}{x-c_1}\right)+(-)[\sqrt{r}]_\infty\\
&= \frac{1}{2x}+(-)\,(0)\\
&= \frac{1}{2x}\\
&= \frac{1}{2x}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p''+2\omega p'+\left(\omega'+\omega^2-r\right)p=0 \tag{1A}
$$

Let

$$
p(x)=1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(\frac{1}{2x}\right)(0)+\left(\left(-\frac{1}{2x^2}\right)+\left(\frac{1}{2x}\right)^2-\left(-\frac{1}{4x^2}\right)\right)=0$$
$$0=0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z''=rz$ is

$$\begin{aligned}z_1(x)&=pe^{\int\omega\,dx}\\&=\mathrm{e}^{\int\frac{1}{2x}dx}\\&=\sqrt{x}\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}y_1&=z_1e^{\int-\frac{1}{2}\frac{B}{A}\,dx}\\&=z_1e^{-\int\frac{1}{2}\frac{-3x^3-2x}{-x^4+2x^2}\,dx}\\&=z_1e^{-\ln(x^2-2)+\frac{\ln(x)}{2}}\\&=z_1\left(\frac{\sqrt{x}}{x^2-2}\right)\end{aligned}$$

Which simplifies to

$$y_1=\frac{x}{x^2-2}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2=y_1\int\frac{e^{\int-\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}y_2&=y_1\int\frac{e^{\int-\frac{-3x^3-2x}{-x^4+2x^2}\,dx}}{(y_1)^2}\,dx\\&=y_1\int\frac{e^{-2\ln(x^2-2)+\ln(x)}}{(y_1)^2}\,dx\\&=y_1(\ln(x))\end{aligned}$$

Therefore the solution is

$$\begin{aligned}y&=c_1y_1+c_2y_2\\&=c_1\left(\frac{x}{x^2-2}\right)+c_2\left(\frac{x}{x^2-2}(\ln(x))\right)\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2(-x^2+2)\left(\frac{d^2}{dx^2}y(x)\right)-x(3x^2+2)\left(\frac{d}{dx}y(x)\right)+(-x^2+2)\,y(x)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x)=-\frac{y(x)}{x^2}-\frac{(3x^2+2)\left(\frac{d}{dx}y(x)\right)}{x(x^2-2)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x)+\frac{(3x^2+2)\left(\frac{d}{dx}y(x)\right)}{x(x^2-2)}+\frac{y(x)}{x^2}=0$

□ Check to see if x_0 is a regular singular point

  - Define functions

    $\left[P_2(x)=\frac{3x^2+2}{x(x^2-2)},P_3(x)=\frac{1}{x^2}\right]$

  - $x\cdot P_2(x)$ is analytic at $x=0$

    $(x\cdot P_2(x))\Big|_{x=0}=-1$

  - $x^2\cdot P_3(x)$ is analytic at $x=0$

    $(x^2\cdot P_3(x))\Big|_{x=0}=1$

  - $x=0$is a regular singular point

    Check to see if x_0 is a regular singular point

    $x_0=0$

- Multiply by denominators

  $x^2(x^2-2)\left(\frac{d^2}{dx^2}y(x)\right)+x(3x^2+2)\left(\frac{d}{dx}y(x)\right)+(x^2-2)\,y(x)=0$

- Assume series solution for $y(x)$

  $y(x)=\sum_{k=0}^{\infty}a_k x^{k+r}$

□ Rewrite ODE with series expansions

  - Convert $x^m\cdot y(x)$ to series expansion for $m=0..2$

    $x^m\cdot y(x)=\sum_{k=0}^{\infty}a_k x^{k+r+m}$

  - Shift index using $k->k-m$

    $x^m\cdot y(x)=\sum_{k=m}^{\infty}a_{k-m}x^{k+r}$

  - Convert $x^m\cdot\left(\frac{d}{dx}y(x)\right)$ to series expansion for $m=1..3$

    $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,x^{k+r-1+m}$

  - Shift index using $k->k+1-m$

    $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,x^{k+r}$

  - Convert $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m=2..4$

    $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,x^{k+r-2+m}$

  - Shift index using $k->k+2-m$

    $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=-2+m}^{\infty}a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$

    Rewrite ODE with series expansions

$$-2a_0(-1+r)^2 x^r - 2a_1 r^2 x^{1+r} + \left(\sum_{k=2}^{\infty} \left(-2a_k(k+r-1)^2 + a_{k-2}(k+r-1)^2\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $-2(-1+r)^2 = 0$
- Values of r that satisfy the indicial equation
  $r = 1$
- Each term must be 0
  $-2a_1 r^2 = 0$
- Solve for the dependent coefficient(s)
  $a_1 = 0$
- Each term in the series must be 0, giving the recursion relation
  $-2\left(a_k - \frac{a_{k-2}}{2}\right)(k+r-1)^2 = 0$
- Shift index using $k- >k+2$
  $-2\left(a_{k+2} - \frac{a_k}{2}\right)(k+r+1)^2 = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+2} = \frac{a_k}{2}$
- Recursion relation for $r = 1$
  $a_{k+2} = \frac{a_k}{2}$
- Solution for $r = 1$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+1}, a_{k+2} = \frac{a_k}{2}, a_1 = 0\right]$

2.1.159 Problem 161

Internal problem ID [9331]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 161
Date solved : `Monday, January 27, 2025 at 06:01:34 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$16x^2\left(x^2+1\right)y''+8x\left(9x^2+1\right)y'+\left(49x^2+1\right)y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.217 (sec)

Writing the ode as

$$\left(16x^4+16x^2\right)y''+\left(72x^3+8x\right)y'+\left(49x^2+1\right)y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 16x^4+16x^2 \\ B &= 72x^3+8x \\ C &= 49x^2+1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{-1}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(-\frac{1}{4x^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.302: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = -\frac{1}{4x^2}$$

Since the gcd$(s, t) = 1$. This gives $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = -\frac{1}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\ &= \frac{1}{2} - \left(\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{1}{2x} + (-)(0) \\ &= \frac{1}{2x} \\ &= \frac{1}{2x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(\frac{1}{2x}\right)(0)+\left(\left(-\frac{1}{2x^2}\right)+\left(\frac{1}{2x}\right)^2-\left(-\frac{1}{4x^2}\right)\right)=0$$
$$0=0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z''=rz$ is

$$\begin{aligned}z_1(x)&=pe^{\int \omega\,dx}\\&=\mathrm{e}^{\int \frac{1}{2x}dx}\\&=\sqrt{x}\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}y_1&=z_1e^{\int -\frac{1}{2}\frac{B}{A}\,dx}\\&=z_1e^{-\int \frac{1}{2}\frac{72x^3+8x}{16x^4+16x^2}\,dx}\\&=z_1e^{-\frac{\ln(x)}{4}-\ln(x^2+1)}\\&=z_1\left(\frac{1}{x^{1/4}\,(x^2+1)}\right)\end{aligned}$$

Which simplifies to

$$y_1=\frac{x^{1/4}}{x^2+1}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2=y_1\int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}y_2&=y_1\int \frac{e^{\int -\frac{72x^3+8x}{16x^4+16x^2}\,dx}}{(y_1)^2}\,dx\\&=y_1\int \frac{e^{-\frac{\ln(x)}{2}-2\ln(x^2+1)}}{(y_1)^2}\,dx\\&=y_1\left(\ln(x)-\ln\left(x^2+1\right)x^2-\ln\left(x^2+1\right)+\frac{x^4}{2x^2+2}+\frac{x^2}{x^2+1}+\frac{1}{2x^2+2}\right.\\&\qquad\left.+\ln\left(x^2+1\right)\left(x^2+1\right)-\frac{x^2}{2}-1\right)\end{aligned}$$

Therefore the solution is

$$\begin{aligned}y&=c_1y_1+c_2y_2\\&=c_1\left(\frac{x^{1/4}}{x^2+1}\right)\\&\quad+c_2\left(\frac{x^{1/4}}{x^2+1}\left(\ln(x)-\ln\left(x^2+1\right)x^2-\ln\left(x^2+1\right)+\frac{x^4}{2x^2+2}+\frac{x^2}{x^2+1}+\frac{1}{2x^2+2}+\ln\left(x^2+1\right)\left(x^2+1\right)-\frac{x^2}{2}\right.\right.\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$16x^2(x^2+1)\left(\frac{d^2}{dx^2}y(x)\right)+8x(9x^2+1)\left(\frac{d}{dx}y(x)\right)+(49x^2+1)\,y(x)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x)=-\frac{(49x^2+1)y(x)}{16x^2(x^2+1)}-\frac{(9x^2+1)\left(\frac{d}{dx}y(x)\right)}{2x(x^2+1)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d^2}{dx^2}y(x)+\frac{(9x^2+1)\left(\frac{d}{dx}y(x)\right)}{2x(x^2+1)}+\frac{(49x^2+1)y(x)}{16x^2(x^2+1)}=0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

  $\left[P_2(x)=\frac{9x^2+1}{2x(x^2+1)}, P_3(x)=\frac{49x^2+1}{16x^2(x^2+1)}\right]$

  ◦ $x\cdot P_2(x)$ is analytic at $x=0$

  $(x\cdot P_2(x))\bigg|_{x=0}=\frac{1}{2}$

  ◦ $x^2\cdot P_3(x)$ is analytic at $x=0$

  $(x^2\cdot P_3(x))\bigg|_{x=0}=\frac{1}{16}$

  ◦ $x=0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=0$

- Multiply by denominators

  $16x^2(x^2+1)\left(\frac{d^2}{dx^2}y(x)\right)+8x(9x^2+1)\left(\frac{d}{dx}y(x)\right)+(49x^2+1)\,y(x)=0$

- Assume series solution for $y(x)$

  $y(x)=\sum_{k=0}^{\infty}a_kx^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $x^m\cdot y(x)$ to series expansion for $m=0..2$

  $x^m\cdot y(x)=\sum_{k=0}^{\infty}a_kx^{k+r+m}$

  ◦ Shift index using $k->k-m$

  $x^m\cdot y(x)=\sum_{k=m}^{\infty}a_{k-m}x^{k+r}$

  ◦ Convert $x^m\cdot\left(\frac{d}{dx}y(x)\right)$ to series expansion for $m=1..3$

  $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,x^{k+r-1+m}$

  ◦ Shift index using $k->k+1-m$

  $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,x^{k+r}$

  ◦ Convert $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m=2..4$

  $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,x^{k+r-2+m}$

  ◦ Shift index using $k->k+2-m$

  $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=-2+m}^{\infty}a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$

  Rewrite ODE with series expansions

$$a_0(-1+4r)^2 x^r + a_1(3+4r)^2 x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(4k+4r-1)^2 + a_{k-2}(4k+4r-1)^2\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $(-1+4r)^2 = 0$
- Values of r that satisfy the indicial equation
  $r = \frac{1}{4}$
- Each term must be 0
  $a_1(3+4r)^2 = 0$
- Solve for the dependent coefficient(s)
  $a_1 = 0$
- Each term in the series must be 0, giving the recursion relation
  $(4k+4r-1)^2 (a_k + a_{k-2}) = 0$
- Shift index using $k- >k+2$
  $(4k+4r+7)^2 (a_{k+2} + a_k) = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+2} = -a_k$
- Recursion relation for $r = \frac{1}{4}$
  $a_{k+2} = -a_k$
- Solution for $r = \frac{1}{4}$

2.1.160 Problem 162

Internal problem ID [9332]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 162
Date solved : `Monday, January 27, 2025 at 06:01:35 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2(4+3x)\,y''-x(4-3x)\,y'+4y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.161 (sec)

Writing the ode as

$$\left(3x^3+4x^2\right)y''+\left(3x^2-4x\right)y'+4y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=3x^3+4x^2\\B&=3x^2-4x\\C&=4\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned}r&=\frac{s}{t}\\&=\frac{2AB'-2BA'+B^2-4AC}{4A^2}\end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{-1}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned}s&=-1\\t&=4x^2\end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(-\frac{1}{4x^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.304: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = -\frac{1}{4x^2}$$

Since the gcd$(s,t)=1$. This gives $b=-\frac{1}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= \frac{1}{2}+\sqrt{1+4b} = \frac{1}{2} \\
\alpha_\infty^{-} &= \frac{1}{2}-\sqrt{1+4b} = \frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = -\frac{1}{4x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-}=\frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^{-} - \left(\alpha_{c_1}^{-}\right) \\
&= \frac{1}{2} - \left(\frac{1}{2}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x-c_1}\right) + (-)[\sqrt{r}]_\infty \\
&= \frac{1}{2x} + (-)\,(0) \\
&= \frac{1}{2x} \\
&= \frac{1}{2x}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
\begin{aligned}
(0)+2\left(\frac{1}{2x}\right)(0)+\left(\left(-\frac{1}{2x^2}\right)+\left(\frac{1}{2x}\right)^2-\left(-\frac{1}{4x^2}\right)\right) &= 0\\
0 &= 0
\end{aligned}
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z''=rz$ is

$$
\begin{aligned}
z_1(x) &= pe^{\int \omega \, dx}\\
&= \mathrm{e}^{\int \frac{1}{2x} dx}\\
&= \sqrt{x}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx}\\
&= z_1 e^{-\int \frac{1}{2}\frac{3x^2-4x}{3x^3+4x^2} \, dx}\\
&= z_1 e^{\frac{\ln(x)}{2}-\ln(4+3x)}\\
&= z_1 \left(\frac{\sqrt{x}}{4+3x}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{x}{4+3x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{3x^2-4x}{3x^3+4x^2} \, dx}}{(y_1)^2} \, dx\\
&= y_1 \int \frac{e^{\ln(x)-2\ln(4+3x)}}{(y_1)^2} \, dx\\
&= y_1 (\ln(x))
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2\\
&= c_1\left(\frac{x}{4+3x}\right) + c_2\left(\frac{x}{4+3x}(\ln(x))\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2(3x+4)\left(\frac{d^2}{dx^2}y(x)\right)-x(4-3x)\left(\frac{d}{dx}y(x)\right)+4y(x)=0$

- Highest derivative means the order of the ODE is 2

$\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

$\frac{d^2}{dx^2}y(x)=-\frac{4y(x)}{x^2(3x+4)}-\frac{(3x-4)\left(\frac{d}{dx}y(x)\right)}{x(3x+4)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

$\frac{d^2}{dx^2}y(x)+\frac{(3x-4)\left(\frac{d}{dx}y(x)\right)}{x(3x+4)}+\frac{4y(x)}{x^2(3x+4)}=0$

□ Check to see if x_0 is a regular singular point

- ◦ Define functions

$\left[P_2(x)=\frac{3x-4}{x(3x+4)},P_3(x)=\frac{4}{x^2(3x+4)}\right]$

- ◦ $x\cdot P_2(x)$ is analytic at $x=0$

$(x\cdot P_2(x))\Big|_{x=0}=-1$

- ◦ $x^2\cdot P_3(x)$ is analytic at $x=0$

$(x^2\cdot P_3(x))\Big|_{x=0}=1$

- ◦ $x=0$is a regular singular point

Check to see if x_0 is a regular singular point

$x_0=0$

- Multiply by denominators

$x^2(3x+4)\left(\frac{d^2}{dx^2}y(x)\right)+x(3x-4)\left(\frac{d}{dx}y(x)\right)+4y(x)=0$

- Assume series solution for $y(x)$

$y(x)=\sum_{k=0}^{\infty}a_kx^{k+r}$

□ Rewrite ODE with series expansions

- ◦ Convert $x^m\cdot\left(\frac{d}{dx}y(x)\right)$ to series expansion for $m=1..2$

$x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,x^{k+r-1+m}$

- ◦ Shift index using $k->k+1-m$

$x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,x^{k+r}$

- ◦ Convert $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m=2..3$

$x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,x^{k+r-2+m}$

- ◦ Shift index using $k->k+2-m$

$x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=-2+m}^{\infty}a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$

Rewrite ODE with series expansions

$4a_0(-1+r)^2\,x^r+\left(\sum_{k=1}^{\infty}\left(4a_k(k+r-1)^2+3a_{k-1}(k+r-1)^2\right)x^{k+r}\right)=0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$4(-1+r)^2=0$

- Values of r that satisfy the indicial equation

$r = 1$

- Each term in the series must be 0, giving the recursion relation

  $(k+r-1)^2 (4a_k + 3a_{k-1}) = 0$

- Shift index using $k- >k+1$

  $(k+r)^2 (4a_{k+1} + 3a_k) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+1} = -\frac{3a_k}{4}$

- Recursion relation for $r = 1$

  $a_{k+1} = -\frac{3a_k}{4}$

- Solution for $r = 1$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+1}, a_{k+1} = -\frac{3a_k}{4}\right]$

2.1.161 Problem 163

Internal problem ID [9333]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 163
Date solved : `Monday, January 27, 2025 at 06:01:35 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$4x^2\left(x^2+3x+1\right)y''+8x^2(3+2x)\,y'+\left(9x^2+3x+1\right)y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.156 (sec)

Writing the ode as

$$\left(4x^4+12x^3+4x^2\right)y''+\left(16x^3+24x^2\right)y'+\left(9x^2+3x+1\right)y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=4x^4+12x^3+4x^2\\B&=16x^3+24x^2\\C&=9x^2+3x+1\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned}r&=\frac{s}{t}\\&=\frac{2AB'-2BA'+B^2-4AC}{4A^2}\end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{-1}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned}s&=-1\\t&=4x^2\end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(-\frac{1}{4x^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.306: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = -\frac{1}{4x^2}$$

Since the gcd$(s,t)=1$. This gives $b=-\frac{1}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0\\
\alpha_\infty^+ &= \frac{1}{2}+\sqrt{1+4b}=\frac{1}{2}\\
\alpha_\infty^- &= \frac{1}{2}-\sqrt{1+4b}=\frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r=-\frac{1}{4x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^-=\frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right)\\
&= \frac{1}{2}-\left(\frac{1}{2}\right)\\
&= 0
\end{aligned}
$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$
\omega=\sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c+\frac{\alpha_c^{s(c)}}{x-c}\right)+s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1}+\frac{\alpha_{c_1}^-}{x-c_1}\right)+(-)[\sqrt{r}]_\infty\\
&= \frac{1}{2x}+(-)\,(0)\\
&= \frac{1}{2x}\\
&= \frac{1}{2x}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p''+2\omega p'+\left(\omega'+\omega^2-r\right)p=0 \tag{1A}
$$

Let

$$
p(x)=1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(\frac{1}{2x}\right)(0)+\left(\left(-\frac{1}{2x^2}\right)+\left(\frac{1}{2x}\right)^2-\left(-\frac{1}{4x^2}\right)\right)=0$$
$$0=0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z''=rz$ is

$$\begin{aligned}z_1(x)&=pe^{\int \omega\,dx}\\&=\mathrm{e}^{\int \frac{1}{2x}dx}\\&=\sqrt{x}\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}y_1&=z_1e^{\int -\frac{1}{2}\frac{B}{A}\,dx}\\&=z_1e^{-\int \frac{1}{2}\frac{16x^3+24x^2}{4x^4+12x^3+4x^2}\,dx}\\&=z_1e^{-\ln(x^2+3x+1)}\\&=z_1\left(\frac{1}{x^2+3x+1}\right)\end{aligned}$$

Which simplifies to

$$y_1=\frac{\sqrt{x}}{x^2+3x+1}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2=y_1\int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}y_2&=y_1\int \frac{e^{\int -\frac{16x^3+24x^2}{4x^4+12x^3+4x^2}\,dx}}{(y_1)^2}\,dx\\&=y_1\int \frac{e^{-2\ln(x^2+3x+1)}}{(y_1)^2}\,dx\\&=y_1(\ln(x))\end{aligned}$$

Therefore the solution is

$$\begin{aligned}y&=c_1y_1+c_2y_2\\&=c_1\left(\frac{\sqrt{x}}{x^2+3x+1}\right)+c_2\left(\frac{\sqrt{x}}{x^2+3x+1}(\ln(x))\right)\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

  $\frac{d^2}{dx^2}y(x)+\frac{2(2x+3)\left(\frac{d}{dx}y(x)\right)}{x^2+3x+1}+\frac{(9x^2+3x+1)y(x)}{4x^2(x^2+3x+1)}=0$

□ Check to see if x_0 is a regular singular point

  - Define functions

    $\left[P_2(x)=\frac{2(2x+3)}{x^2+3x+1},P_3(x)=\frac{9x^2+3x+1}{4x^2(x^2+3x+1)}\right]$

  - $x\cdot P_2(x)$ is analytic at $x=0$

    $(x\cdot P_2(x))\bigg|_{x=0}=0$

  - $x^2\cdot P_3(x)$ is analytic at $x=0$

    $(x^2\cdot P_3(x))\bigg|_{x=0}=\frac{1}{4}$

  - $x=0$is a regular singular point

    Check to see if x_0 is a regular singular point

    $x_0=0$

- Multiply by denominators

  $4x^2(x^2+3x+1)\left(\frac{d^2}{dx^2}y(x)\right)+8x^2(2x+3)\left(\frac{d}{dx}y(x)\right)+(9x^2+3x+1)\,y(x)=0$

- Assume series solution for $y(x)$

  $y(x)=\sum_{k=0}^{\infty}a_kx^{k+r}$

□ Rewrite ODE with series expansions

  - Convert $x^m\cdot y(x)$ to series expansion for $m=0..2$

    $x^m\cdot y(x)=\sum_{k=0}^{\infty}a_kx^{k+r+m}$

  - Shift index using $k->k-m$

    $x^m\cdot y(x)=\sum_{k=m}^{\infty}a_{k-m}x^{k+r}$

  - Convert $x^m\cdot\left(\frac{d}{dx}y(x)\right)$ to series expansion for $m=2..3$

    $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,x^{k+r-1+m}$

  - Shift index using $k->k+1-m$

    $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,x^{k+r}$

  - Convert $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m=2..4$

    $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,x^{k+r-2+m}$

  - Shift index using $k->k+2-m$

    $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=-2+m}^{\infty}a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$

  Rewrite ODE with series expansions

$$a_0(-1+2r)^2 x^r + \left(a_1(1+2r)^2 + 3a_0(1+2r)^2\right) x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(2k+2r-1)^2 + 3a_{k-1}(2k+2r-1\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $(-1+2r)^2 = 0$
- Values of r that satisfy the indicial equation
  $r = \frac{1}{2}$
- Each term must be 0
  $a_1(1+2r)^2 + 3a_0(1+2r)^2 = 0$
- Solve for the dependent coefficient(s)
  $a_1 = -3a_0$
- Each term in the series must be 0, giving the recursion relation
  $(2k+2r-1)^2 (a_k + 3a_{k-1} + a_{k-2}) = 0$
- Shift index using $k- >k+2$
  $(2k+2r+3)^2 (a_{k+2} + 3a_{k+1} + a_k) = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+2} = -3a_{k+1} - a_k$
- Recursion relation for $r = \frac{1}{2}$
  $a_{k+2} = -3a_{k+1} - a_k$
- Solution for $r = \frac{1}{2}$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}, a_{k+2} = -3a_{k+1} - a_k, a_1 = -3a_0\right]$

2.1.162 Problem 164

Internal problem ID [9334]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 164
Date solved : `Monday, January 27, 2025 at 06:01:36 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2(1-x)^2 y'' - x\left(-3x^2+2x+1\right) y' + \left(x^2+1\right) y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.159 (sec)

Writing the ode as

$$x^2(-1+x)^2 y'' + \left(3x^3-2x^2-x\right) y' + \left(x^2+1\right) y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2(-1+x)^2 \\ B &= 3x^3-2x^2-x \\ C &= x^2+1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{1}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.308: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = -\frac{1}{4x^2}$$

Since the gcd$(s,t)=1$. This gives $b=-\frac{1}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= 0\\ \alpha_\infty^{+} &= \frac{1}{2}+\sqrt{1+4b}=\frac{1}{2}\\ \alpha_\infty^{-} &= \frac{1}{2}-\sqrt{1+4b}=\frac{1}{2}\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r=-\frac{1}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-}=\frac{1}{2}$ then

$$\begin{aligned}d &= \alpha_\infty^{-}-\left(\alpha_{c_1}^{-}\right)\\ &= \frac{1}{2}-\left(\frac{1}{2}\right)\\ &= 0\end{aligned}$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$\omega=\sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c+\frac{\alpha_c^{s(c)}}{x-c}\right)+s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}\omega &= \left((-)[\sqrt{r}]_{c_1}+\frac{\alpha_{c_1}^{-}}{x-c_1}\right)+(-)[\sqrt{r}]_\infty\\ &= \frac{1}{2x}+(-)\,(0)\\ &= \frac{1}{2x}\\ &= \frac{1}{2x}\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p''+2\omega p'+\left(\omega'+\omega^2-r\right)p=0 \tag{1A}$$

Let

$$p(x)=1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(\frac{1}{2x}\right)(0)+\left(\left(-\frac{1}{2x^2}\right)+\left(\frac{1}{2x}\right)^2-\left(-\frac{1}{4x^2}\right)\right)=0$$
$$0=0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z''=rz$ is

$$\begin{aligned}z_1(x)&=pe^{\int \omega\,dx}\\&=\mathrm{e}^{\int \frac{1}{2x}dx}\\&=\sqrt{x}\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}y_1&=z_1e^{\int -\frac{1}{2}\frac{B}{A}\,dx}\\&=z_1e^{-\int \frac{1}{2}\frac{3x^3-2x^2-x}{x^2(-1+x)^2}\,dx}\\&=z_1e^{-2\ln(-1+x)+\frac{\ln(x)}{2}}\\&=z_1\left(\frac{\sqrt{x}}{(-1+x)^2}\right)\end{aligned}$$

Which simplifies to

$$y_1=\frac{x}{(-1+x)^2}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2=y_1\int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}y_2&=y_1\int \frac{e^{\int -\frac{3x^3-2x^2-x}{x^2(-1+x)^2}\,dx}}{(y_1)^2}\,dx\\&=y_1\int \frac{e^{-4\ln(-1+x)+\ln(x)}}{(y_1)^2}\,dx\\&=y_1(\ln(x))\end{aligned}$$

Therefore the solution is

$$\begin{aligned}y&=c_1y_1+c_2y_2\\&=c_1\left(\frac{x}{(-1+x)^2}\right)+c_2\left(\frac{x}{(-1+x)^2}(\ln(x))\right)\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2(1-x)^2\left(\frac{d^2}{dx^2}y(x)\right)-x(-3x^2+2x+1)\left(\frac{d}{dx}y(x)\right)+(x^2+1)\,y(x)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x)=-\frac{(x^2+1)y(x)}{x^2(x-1)^2}-\frac{\left(\frac{d}{dx}y(x)\right)(3x+1)}{x(x-1)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x)+\frac{\left(\frac{d}{dx}y(x)\right)(3x+1)}{x(x-1)}+\frac{(x^2+1)y(x)}{x^2(x-1)^2}=0$

☐ Check to see if x_0 is a regular singular point

- ○ Define functions

  $\left[P_2(x)=\frac{3x+1}{x(x-1)},P_3(x)=\frac{x^2+1}{x^2(x-1)^2}\right]$

- ○ $x\cdot P_2(x)$ is analytic at $x=0$

  $(x\cdot P_2(x))\bigg|_{x=0}=-1$

- ○ $x^2\cdot P_3(x)$ is analytic at $x=0$

  $(x^2\cdot P_3(x))\bigg|_{x=0}=1$

- ○ $x=0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=0$

- Multiply by denominators

  $x^2(x-1)^2\left(\frac{d^2}{dx^2}y(x)\right)+x(x-1)(3x+1)\left(\frac{d}{dx}y(x)\right)+(x^2+1)\,y(x)=0$

- Assume series solution for $y(x)$

  $y(x)=\sum_{k=0}^{\infty}a_kx^{k+r}$

☐ Rewrite ODE with series expansions

- ○ Convert $x^m\cdot y(x)$ to series expansion for $m=0..2$

  $x^m\cdot y(x)=\sum_{k=0}^{\infty}a_kx^{k+r+m}$

- ○ Shift index using $k->k-m$

  $x^m\cdot y(x)=\sum_{k=m}^{\infty}a_{k-m}x^{k+r}$

- ○ Convert $x^m\cdot\left(\frac{d}{dx}y(x)\right)$ to series expansion for $m=1..3$

  $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,x^{k+r-1+m}$

- ○ Shift index using $k->k+1-m$

  $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,x^{k+r}$

- ○ Convert $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m=2..4$

  $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,x^{k+r-2+m}$

- ○ Shift index using $k->k+2-m$

  $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=-2+m}^{\infty}a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$

Rewrite ODE with series expansions

$$a_0(-1+r)^2 x^r + (-2a_0r^2 + a_1r^2) x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(k+r-1)^2 - 2a_{k-1}(k+r-1)^2 + a_{k-2}(k+r\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $(-1+r)^2 = 0$
- Values of r that satisfy the indicial equation
  $r = 1$
- Each term must be 0
  $-2a_0r^2 + a_1r^2 = 0$
- Solve for the dependent coefficient(s)
  $a_1 = 2a_0$
- Each term in the series must be 0, giving the recursion relation
  $(k+r-1)^2 (a_k - 2a_{k-1} + a_{k-2}) = 0$
- Shift index using $k->k+2$
  $(k+r+1)^2 (a_{k+2} - 2a_{k+1} + a_k) = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+2} = 2a_{k+1} - a_k$
- Recursion relation for $r = 1$
  $a_{k+2} = 2a_{k+1} - a_k$
- Solution for $r = 1$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+1}, a_{k+2} = 2a_{k+1} - a_k, a_1 = 2a_0\right]$

2.1.163 Problem 165

Internal problem ID [9335]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 165
Date solved : `Monday, January 27, 2025 at 06:01:37 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$9x^2\left(x^2+x+1\right)y''+3x\left(13x^2+7x+1\right)y'+\left(25x^2+4x+1\right)y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.267 (sec)

Writing the ode as

$$\left(9x^4+9x^3+9x^2\right)y''+\left(39x^3+21x^2+3x\right)y'+\left(25x^2+4x+1\right)y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 9x^4+9x^3+9x^2 \\ B &= 39x^3+21x^2+3x \\ C &= 25x^2+4x+1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{-1}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(-\frac{1}{4x^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.310: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = -\frac{1}{4x^2}$$

Since the gcd$(s,t) = 1$. This gives $b = -\frac{1}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = -\frac{1}{4x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^- - (\alpha_{c_1}^-) \\
&= \frac{1}{2} - \left(\frac{1}{2}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\
&= \frac{1}{2x} + (-)\,(0) \\
&= \frac{1}{2x} \\
&= \frac{1}{2x}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(\frac{1}{2x}\right)(0)+\left(\left(-\frac{1}{2x^2}\right)+\left(\frac{1}{2x}\right)^2-\left(-\frac{1}{4x^2}\right)\right)=0$$
$$0=0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z''=rz$ is

$$\begin{aligned} z_1(x) &= pe^{\int \omega\,dx} \\ &= \mathrm{e}^{\int \frac{1}{2x}dx} \\ &= \sqrt{x} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{39x^3+21x^2+3x}{9x^4+9x^3+9x^2}\,dx} \\ &= z_1 e^{-\ln(x^2+x+1)-\frac{\ln(x)}{6}} \\ &= z_1\left(\frac{1}{(x^2+x+1)\,x^{1/6}}\right) \end{aligned}$$

Which simplifies to

$$y_1=\frac{x^{1/3}}{x^2+x+1}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2=y_1\int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1\int \frac{e^{\int -\frac{39x^3+21x^2+3x}{9x^4+9x^3+9x^2}\,dx}}{(y_1)^2}\,dx \\ &= y_1\int \frac{e^{-2\ln(x^2+x+1)-\frac{\ln(x)}{3}}}{(y_1)^2}\,dx \\ &= y_1\left(2x-\frac{19}{24}+(x-1)^2-\frac{x^5}{3(x^2+x+1)}+\frac{x}{3x^2+3x+3}-\frac{x^4}{3(x^2+x+1)}\right. \\ &\qquad \left.-\frac{x^3}{3(x^2+x+1)}+\frac{x^2}{3x^2+3x+3}+\frac{1}{3x^2+3x+3}+\frac{x^3}{3}-x^2+\ln(x)\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1y_1+c_2y_2 \\ &= c_1\left(\frac{x^{1/3}}{x^2+x+1}\right) \\ &\quad +c_2\left(\frac{x^{1/3}}{x^2+x+1}\left(2x-\frac{19}{24}+(x-1)^2-\frac{x^5}{3(x^2+x+1)}+\frac{x}{3x^2+3x+3}-\frac{x^4}{3(x^2+x+1)}-\frac{x^3}{3(x^2+x+1)}+\frac{}{3\ldots}\right.\right. \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$9x^2(x^2+x+1)\left(\frac{d^2}{dx^2}y(x)\right)+3x(13x^2+7x+1)\left(\frac{d}{dx}y(x)\right)+(25x^2+4x+1)\,y(x)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x)=-\frac{(25x^2+4x+1)y(x)}{9x^2(x^2+x+1)}-\frac{(13x^2+7x+1)\left(\frac{d}{dx}y(x)\right)}{3x(x^2+x+1)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x)+\frac{(13x^2+7x+1)\left(\frac{d}{dx}y(x)\right)}{3x(x^2+x+1)}+\frac{(25x^2+4x+1)y(x)}{9x^2(x^2+x+1)}=0$

□ Check to see if x_0 is a regular singular point

- ◦ Define functions

  $\left[P_2(x)=\frac{13x^2+7x+1}{3x(x^2+x+1)},P_3(x)=\frac{25x^2+4x+1}{9x^2(x^2+x+1)}\right]$

- ◦ $x\cdot P_2(x)$ is analytic at $x=0$

  $\left(x\cdot P_2(x)\right)\bigg|_{x=0}=\frac{1}{3}$

- ◦ $x^2\cdot P_3(x)$ is analytic at $x=0$

  $\left(x^2\cdot P_3(x)\right)\bigg|_{x=0}=\frac{1}{9}$

- ◦ $x=0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=0$

- Multiply by denominators

  $9x^2(x^2+x+1)\left(\frac{d^2}{dx^2}y(x)\right)+3x(13x^2+7x+1)\left(\frac{d}{dx}y(x)\right)+(25x^2+4x+1)\,y(x)=0$

- Assume series solution for $y(x)$

  $y(x)=\sum_{k=0}^{\infty}a_kx^{k+r}$

□ Rewrite ODE with series expansions

- ◦ Convert $x^m\cdot y(x)$ to series expansion for $m=0..2$

  $x^m\cdot y(x)=\sum_{k=0}^{\infty}a_kx^{k+r+m}$

- ◦ Shift index using $k->k-m$

  $x^m\cdot y(x)=\sum_{k=m}^{\infty}a_{k-m}x^{k+r}$

- ◦ Convert $x^m\cdot\left(\frac{d}{dx}y(x)\right)$ to series expansion for $m=1..3$

  $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,x^{k+r-1+m}$

- ◦ Shift index using $k->k+1-m$

  $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,x^{k+r}$

- ◦ Convert $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m=2..4$

  $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,x^{k+r-2+m}$

- ◦ Shift index using $k->k+2-m$

  $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=-2+m}^{\infty}a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$

  Rewrite ODE with series expansions

$$a_0(-1+3r)^2 x^r + \left(a_1(2+3r)^2 + a_0(2+3r)^2\right) x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(3k+3r-1)^2 + a_{k-1}(3k+3r-1)^2\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $(-1+3r)^2 = 0$
- Values of r that satisfy the indicial equation
  $r = \frac{1}{3}$
- Each term must be 0
  $a_1(2+3r)^2 + a_0(2+3r)^2 = 0$
- Solve for the dependent coefficient(s)
  $a_1 = -a_0$
- Each term in the series must be 0, giving the recursion relation
  $(3k+3r-1)^2 (a_k + a_{k-1} + a_{k-2}) = 0$
- Shift index using $k- >k+2$
  $(3k+3r+5)^2 (a_{k+2} + a_{k+1} + a_k) = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+2} = -a_{k+1} - a_k$
- Recursion relation for $r = \frac{1}{3}$
  $a_{k+2} = -a_{k+1} - a_k$
- Solution for $r = \frac{1}{3}$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{3}}, a_{k+2} = -a_{k+1} - a_k, a_1 = -a_0\right]$

Solve

$$2x^2(2+x)\,y''-x(4-7x)\,y'-(5-3x)\,y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.219 (sec)

Writing the ode as

$$\left(2x^3+4x^2\right)y''+\left(7x^2-4x\right)y'+(3x-5)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2x^3+4x^2 \\ B &= 7x^2-4x \\ C &= 3x-5 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{-3x^2-32x+128}{16\left(x^2+2x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -3x^2-32x+128 \\ t &= 16\left(x^2+2x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{-3x^2-32x+128}{16\left(x^2+2x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.312: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16(x^2 + 2x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -2$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{45}{16\,(2+x)^2} - \frac{5}{2x} + \frac{2}{x^2} + \frac{5}{2\,(2+x)}$$

For the pole at $x = -2$ let b be the coefficient of $\frac{1}{(2+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{45}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{9}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{5}{4} \end{aligned}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1 \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{-3x^2 - 32x + 128}{16\left(x^2 + 2x\right)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{3}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{4} \\ \alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{4} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{-3x^2 - 32x + 128}{16\left(x^2 + 2x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
-2	2	0	$\frac{9}{4}$	$-\frac{5}{4}$
0	2	0	2	-1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{3}{4}$	$\frac{1}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{3}{4}$ then

$$\begin{aligned} d &= \alpha_\infty^+ - \left(\alpha_{c_1}^- + \alpha_{c_2}^+\right) \\ &= \frac{3}{4} - \left(\frac{3}{4}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x-c_2} \right) + (+)[\sqrt{r}]_\infty \\ &= -\frac{5}{4\left(2+x\right)} + \frac{2}{x} + (0) \\ &= -\frac{5}{4\left(2+x\right)} + \frac{2}{x} \\ &= \frac{3x+16}{4x\left(2+x\right)} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{5}{4(2+x)} + \frac{2}{x}\right)(0) + \left(\left(\frac{5}{4(2+x)^2} - \frac{2}{x^2}\right) + \left(-\frac{5}{4(2+x)} + \frac{2}{x}\right)^2 - \left(\frac{-3x^2 - 32x + 128}{16(x^2+2x)^2}\right)\right) =$$

$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(-\frac{5}{4(2+x)} + \frac{2}{x}\right) dx} \\
&= \frac{x^2}{(2+x)^{5/4}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{7x^2-4x}{2x^3+4x^2}\, dx} \\
&= z_1 e^{-\frac{9\ln(2+x)}{4} + \frac{\ln(x)}{2}} \\
&= z_1 \left(\frac{\sqrt{x}}{(2+x)^{9/4}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{x^{5/2}}{(2+x)^{7/2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{7x^2-4x}{2x^3+4x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-\frac{9\ln(2+x)}{2} + \ln(x)}}{(y_1)^2}\, dx \\
&= y_1 \left(\frac{-\frac{11(2+x)^{5/2}}{8} + \frac{10(2+x)^{3/2}}{3} - \frac{5\sqrt{2+x}}{2}}{x^3} - \frac{5\sqrt{2}\,\operatorname{arctanh}\left(\frac{\sqrt{2+x}\,\sqrt{2}}{2}\right)}{16}\right)
\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{x^{5/2}}{(2+x)^{7/2}}\right) \\
&\quad + c_2 \left(\frac{x^{5/2}}{(2+x)^{7/2}} \left(\frac{-\frac{11(2+x)^{5/2}}{8} + \frac{10(2+x)^{3/2}}{3} - \frac{5\sqrt{2+x}}{2}}{x^3} - \frac{5\sqrt{2}\,\mathrm{arctanh}\left(\frac{\sqrt{2+x}\,\sqrt{2}}{2}\right)}{16}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$2x^2(x+2)\left(\frac{d^2}{dx^2}y(x)\right) - x(4-7x)\left(\frac{d}{dx}y(x)\right) - (5-3x)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{(3x-5)y(x)}{2(x+2)x^2} - \frac{(-4+7x)\left(\frac{d}{dx}y(x)\right)}{2x(x+2)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x) + \frac{(-4+7x)\left(\frac{d}{dx}y(x)\right)}{2x(x+2)} + \frac{(3x-5)y(x)}{2(x+2)x^2} = 0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

    $\left[P_2(x) = \frac{-4+7x}{2x(x+2)}, P_3(x) = \frac{3x-5}{2(x+2)x^2}\right]$

  ◦ $(x+2)\cdot P_2(x)$ is analytic at $x=-2$

  ◦ $(x+2)^2\cdot P_3(x)$ is analytic at $x=-2$

    $\left((x+2)^2\cdot P_3(x)\right)\bigg|_{x=-2} = 0$

  ◦ $x=-2$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = -2$

- Multiply by denominators

  $2x^2(x+2)\left(\frac{d^2}{dx^2}y(x)\right) + x(-4+7x)\left(\frac{d}{dx}y(x)\right) + (3x-5)\,y(x) = 0$

- Change variables using $x=u-2$ so that the regular singular point is at $u=0$

  $(2u^3 - 8u^2 + 8u)\left(\frac{d^2}{du^2}y(u)\right) + (7u^2 - 32u + 36)\left(\frac{d}{du}y(u)\right) + (3u-11)\,y(u) = 0$

- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $u^m\cdot y(u)$ to series expansion for $m=0..1$

    $u^m\cdot y(u) = \sum_{k=0}^{\infty} a_k u^{k+r+m}$

  ◦ Shift index using $k->k-m$

    $u^m\cdot y(u) = \sum_{k=m}^{\infty} a_{k-m} u^{k+r}$

  ◦ Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..2$

$$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, u^{k+r-1+m}$$

- Shift index using $k->k+1-m$

$$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$$

- Convert $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m = 1..3$

$$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, u^{k+r-2+m}$$

- Shift index using $k->k+2-m$

$$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, u^{k+r}$$

Rewrite ODE with series expansions

$$4a_0r(7+2r)\, u^{-1+r} + (4a_1(1+r)\,(9+2r) - a_0(8r^2+24r+11))\, u^r + \left(\sum_{k=1}^{\infty} (4a_{k+1}(k+r+1)\,(2k\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $4r(7+2r) = 0$
- Values of r that satisfy the indicial equation
  $r \in \left\{0, -\frac{7}{2}\right\}$
- Each term must be 0
  $4a_1(1+r)\,(9+2r) - a_0(8r^2+24r+11) = 0$
- Each term in the series must be 0, giving the recursion relation
  $2(-4a_k + a_{k-1} + 4a_{k+1})\, k^2 + (4(-4a_k + a_{k-1} + 4a_{k+1})\, r - 24a_k + a_{k-1} + 44a_{k+1})\, k + 2(-4a_k +$
- Shift index using $k->k+1$
  $2(-4a_{k+1} + a_k + 4a_{k+2})\,(k+1)^2 + (4(-4a_{k+1} + a_k + 4a_{k+2})\, r - 24a_{k+1} + a_k + 44a_{k+2})\,(k+1)$
- Recursion relation that defines series solution to ODE
  $a_{k+2} = -\frac{2k^2a_k - 8k^2a_{k+1} + 4kra_k - 16kra_{k+1} + 2r^2a_k - 8r^2a_{k+1} + 5ka_k - 40ka_{k+1} + 5ra_k - 40ra_{k+1} + 3a_k - 43a_{k+1}}{4(2k^2+4kr+2r^2+15k+15r+22)}$
- Recursion relation for $r = 0$
  $a_{k+2} = -\frac{2k^2a_k - 8k^2a_{k+1} + 5ka_k - 40ka_{k+1} + 3a_k - 43a_{k+1}}{4(2k^2+15k+22)}$
- Solution for $r = 0$
  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+2} = -\frac{2k^2a_k - 8k^2a_{k+1} + 5ka_k - 40ka_{k+1} + 3a_k - 43a_{k+1}}{4(2k^2+15k+22)}, 36a_1 - 11a_0 = 0\right]$
- Revert the change of variables $u = x+2$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k(x+2)^k, a_{k+2} = -\frac{2k^2a_k - 8k^2a_{k+1} + 5ka_k - 40ka_{k+1} + 3a_k - 43a_{k+1}}{4(2k^2+15k+22)}, 36a_1 - 11a_0 = 0\right]$
- Recursion relation for $r = -\frac{7}{2}$
  $a_{k+2} = -\frac{2k^2a_k - 8k^2a_{k+1} - 9ka_k + 16ka_{k+1} + 10a_k - a_{k+1}}{4(2k^2+k-6)}$
- Solution for $r = -\frac{7}{2}$
  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k-\frac{7}{2}}, a_{k+2} = -\frac{2k^2a_k - 8k^2a_{k+1} - 9ka_k + 16ka_{k+1} + 10a_k - a_{k+1}}{4(2k^2+k-6)}, -20a_1 - 25a_0 = 0\right]$

2.1.165 Problem 167

Internal problem ID [9337]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 167
Date solved : `Monday, January 27, 2025 at 06:01:38 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2(1-2x)\,y''+x(8-9x)\,y'+(6-3x)\,y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.208 (sec)

Writing the ode as

$$\left(-2x^3+x^2\right)y''+\left(-9x^2+8x\right)y'+(6-3x)\,y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= -2x^3+x^2 \\ B &= -9x^2+8x \\ C &= 6-3x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{21x^2-20x+24}{4\left(2x^2-x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 21x^2-20x+24 \\ t &= 4\left(2x^2-x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{21x^2-20x+24}{4\left(2x^2-x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.314: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(2x^2 - x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = \frac{1}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{6}{x^2} + \frac{19}{x} + \frac{77}{16\left(x - \frac{1}{2}\right)^2} - \frac{19}{x - \frac{1}{2}}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = 6$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 3 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -2 \end{aligned}$$

For the pole at $x = \frac{1}{2}$ let b be the coefficient of $\frac{1}{\left(x-\frac{1}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{77}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{11}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{7}{4} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{21x^2 - 20x + 24}{4\left(2x^2 - x\right)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{21}{16}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{4} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{4}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{21x^2 - 20x + 24}{4\left(2x^2 - x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	3	-2
$\frac{1}{2}$	2	0	$\frac{11}{4}$	$-\frac{7}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{7}{4}$	$-\frac{3}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{7}{4}$ then

$$\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^- + \alpha_{c_2}^+\right) \\
&= \frac{7}{4} - \left(\frac{3}{4}\right) \\
&= 1
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x-c_2} \right) + (+)[\sqrt{r}]_\infty \\
&= -\frac{2}{x} + \frac{11}{4\left(x-\frac{1}{2}\right)} + (0) \\
&= -\frac{2}{x} + \frac{11}{4\left(x-\frac{1}{2}\right)} \\
&= \frac{4+3x}{4x^2 - 2x}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p''+2\omega p'+\left(\omega'+\omega^2-r\right)p=0 \tag{1A}$$

Let

$$p(x)=x+a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(-\frac{2}{x}+\frac{11}{4\left(x-\frac{1}{2}\right)}\right)(1)+\left(\left(\frac{2}{x^2}-\frac{11}{4\left(x-\frac{1}{2}\right)^2}\right)+\left(-\frac{2}{x}+\frac{11}{4\left(x-\frac{1}{2}\right)}\right)^2-\left(\frac{21x^2-20x+24}{4\left(2x^2-x\right)^2}\right)\right)=\frac{4-3a_0}{x\left(-1+2x\right)}=0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\left\{a_0=\frac{4}{3}\right\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x)=x+\frac{4}{3}$$

Therefore the first solution to the ode $z''=rz$ is

$$\begin{aligned}
z_1(x)&=pe^{\int \omega\, dx}\\
&=\left(x+\frac{4}{3}\right)\mathrm{e}^{\int\left(-\frac{2}{x}+\frac{11}{4\left(x-\frac{1}{2}\right)}\right)dx}\\
&=\left(x+\frac{4}{3}\right)\mathrm{e}^{\frac{11\ln(-1+2x)}{4}-2\ln(x)}\\
&=\frac{\left(x+\frac{4}{3}\right)\left(-1+2x\right)^{11/4}}{x^2}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1&=z_1e^{\int -\frac{1}{2}\frac{B}{A}\,dx}\\
&=z_1e^{-\int \frac{1}{2}\frac{-9x^2+8x}{-2x^3+x^2}\,dx}\\
&=z_1e^{\frac{7\ln(-1+2x)}{4}-4\ln(x)}\\
&=z_1\left(\frac{\left(-1+2x\right)^{7/4}}{x^4}\right)
\end{aligned}$$

Which simplifies to

$$y_1=\frac{\left(-1+2x\right)^{9/2}\left(4+3x\right)}{3x^6}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2=y_1\int\frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-9x^2+8x}{-2x^3+x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{\frac{7\ln(-1+2x)}{2}-8\ln(x)}}{(y_1)^2}\, dx \\
&= y_1 \left(-\frac{(231x^3-198x^2+66x-8)\, x^8 \mathrm{e}^{\frac{7\ln(-1+2x)}{2}-8\ln(x)}}{385\,(4+3x)\,(-1+2x)^8} \right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{(-1+2x)^{9/2}\,(4+3x)}{3x^6} \right) \\
&\quad + c_2 \left(\frac{(-1+2x)^{9/2}\,(4+3x)}{3x^6} \left(-\frac{(231x^3-198x^2+66x-8)\, x^8 \mathrm{e}^{\frac{7\ln(-1+2x)}{2}-8\ln(x)}}{385\,(4+3x)\,(-1+2x)^8} \right) \right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2(-2x+1)\left(\frac{d^2}{dx^2}y(x)\right) + x(8-9x)\left(\frac{d}{dx}y(x)\right) + (6-3x)\, y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{3(x-2)y(x)}{x^2(2x-1)} - \frac{(-8+9x)\left(\frac{d}{dx}y(x)\right)}{x(2x-1)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x) + \frac{(-8+9x)\left(\frac{d}{dx}y(x)\right)}{x(2x-1)} + \frac{3(x-2)y(x)}{x^2(2x-1)} = 0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

  $\left[P_2(x) = \frac{-8+9x}{x(2x-1)}, P_3(x) = \frac{3(x-2)}{x^2(2x-1)}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

  $\left.(x \cdot P_2(x))\right|_{x=0} = 8$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $\left.(x^2 \cdot P_3(x))\right|_{x=0} = 6$

  ◦ $x = 0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $x^2(2x-1)\left(\frac{d^2}{dx^2}y(x)\right) + x(-8+9x)\left(\frac{d}{dx}y(x)\right) + (3x-6)\, y(x) = 0$

- Assume series solution for $y(x)$

$y(x)=\sum_{k=0}^{\infty} a_k x^{k+r}$

- ☐ Rewrite ODE with series expansions
  - ○ Convert $x^m \cdot y(x)$ to series expansion for $m=0..1$

    $x^m \cdot y(x)=\sum_{k=0}^{\infty} a_k x^{k+r+m}$
  - ○ Shift index using $k->k-m$

    $x^m \cdot y(x)=\sum_{k=m}^{\infty} a_{k-m} x^{k+r}$
  - ○ Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m=1..2$

    $x^m \cdot \left(\frac{d}{dx}y(x)\right)=\sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1+m}$
  - ○ Shift index using $k->k+1-m$

    $x^m \cdot \left(\frac{d}{dx}y(x)\right)=\sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$
  - ○ Convert $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m=2..3$

    $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-2+m}$
  - ○ Shift index using $k->k+2-m$

    $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, x^{k+r}$

  Rewrite ODE with series expansions

  $-a_0(6+r)\,(1+r)\, x^r+\left(\sum_{k=1}^{\infty}\left(-a_k(k+r+6)\,(k+r+1)+a_{k-1}(k+2+r)\,(2k-1+2r)\right) x^{k+r}\right)=$
- $a_0$cannot be 0 by assumption, giving the indicial equation

  $-(6+r)\,(1+r)=0$
- Values of r that satisfy the indicial equation

  $r\in\{-6,-1\}$
- Each term in the series must be 0, giving the recursion relation

  $2(k+2+r)\left(k+r-\frac{1}{2}\right)a_{k-1}-a_k(k+r+6)\,(k+r+1)=0$
- Shift index using $k->k+1$

  $2(k+r+3)\left(k+\frac{1}{2}+r\right)a_k-a_{k+1}(k+7+r)\,(k+2+r)=0$
- Recursion relation that defines series solution to ODE

  $a_{k+1}=\frac{(k+r+3)(2k+2r+1)a_k}{(k+7+r)(k+2+r)}$
- Recursion relation for $r=-6$; series terminates at $k=3$

  $a_{k+1}=\frac{(k-3)(2k-11)a_k}{(k+1)(k-4)}$
- Apply recursion relation for $k=0$

  $a_1=-\frac{33a_0}{4}$
- Apply recursion relation for $k=1$

  $a_2=-3a_1$
- Express in terms of a_0

  $a_2=\frac{99a_0}{4}$
- Apply recursion relation for $k=2$

  $a_3=-\frac{7a_2}{6}$
- Express in terms of a_0

  $a_3=-\frac{231a_0}{8}$
- Terminating series solution of the ODE for $r=-6$. Use reduction of order to find the second lin

  $y(x)=a_0\cdot\left(-\frac{231}{8}x^3+\frac{99}{4}x^2-\frac{33}{4}x+1\right)$

- Recursion relation for $r = -1$

  $a_{k+1} = \frac{(k+2)(2k-1)a_k}{(k+6)(k+1)}$
- Solution for $r = -1$

  $$\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k-1}, a_{k+1} = \frac{(k+2)(2k-1)a_k}{(k+6)(k+1)}\right]$$
- Combine solutions and rename parameters

  $$\left[y(x) = a_0 \cdot \left(-\frac{231}{8}x^3 + \frac{99}{4}x^2 - \frac{33}{4}x + 1\right) + \left(\sum_{k=0}^{\infty} b_k x^{k-1}\right), b_{k+1} = \frac{(k+2)(2k-1)b_k}{(k+6)(k+1)}\right]$$

$$y(x) \to \frac{1}{3}(3x+4)\exp\left(\int_1^x -\frac{3K[1]+4}{2K[1]-4K[1]^2}dK[1] - \frac{1}{2}\int_1^x \frac{8-9K[2]}{K[2]-2K[2]^2}dK[2]\right)\left(c_2\int_1^x \frac{9\exp\left(-2\int_1^{K[3]} -\frac{3K[1]+4}{2K[1]-4K[1]^2}dK[1]\right)}{(3K[3]+4)^2}dK[3] + c_1\right)$$

2.1.166 Problem 168

Internal problem ID [9338]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 168
Date solved : `Monday, January 27, 2025 at 06:01:38 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2 (x^2+1) y''+x(10x^2+3) y'-(-14x^2+15) y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.323 (sec)

Writing the ode as

$$(x^4+x^2) y''+(10x^3+3x) y'+(14x^2-15) y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A&=x^4+x^2\\ B&=10x^3+3x\\ C&=14x^2-15 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r&=\frac{s}{t}\\ &=\frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{24x^4+66x^2+63}{4\left(x^3+x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s&=24x^4+66x^2+63\\ t&=4\left(x^3+x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{24x^4+66x^2+63}{4\left(x^3+x\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.316: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 4 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^3 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = i$ of order 2. There is a pole at $x = -i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{21}{16 (x - i)^2} + \frac{21}{16 (x + i)^2} + \frac{99i}{16 (x - i)} - \frac{99i}{16 (x + i)} + \frac{63}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{63}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{9}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{7}{2} \end{aligned}$$

For the pole at $x = i$ let b be the coefficient of $\frac{1}{(x-i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{21}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{7}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{3}{4} \end{aligned}$$

For the pole at $x=-i$ let b be the coefficient of $\frac{1}{(x+i)^2}$ in the partial fractions decomposition of r given above. Therefore $b=\frac{21}{16}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2}+\sqrt{1+4b}=\frac{7}{4} \\
\alpha_c^- &= \frac{1}{2}-\sqrt{1+4b}=-\frac{3}{4}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty=0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r=\frac{s}{t}=\frac{24x^4+66x^2+63}{4\left(x^3+x\right)^2}
$$

Since the $\gcd(s,t)=1$. This gives $b=6$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2}+\sqrt{1+4b}=3 \\
\alpha_\infty^- &= \frac{1}{2}-\sqrt{1+4b}=-2
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r=\frac{24x^4+66x^2+63}{4\left(x^3+x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{9}{2}$	$-\frac{7}{2}$
i	2	0	$\frac{7}{4}$	$-\frac{3}{4}$
$-i$	2	0	$\frac{7}{4}$	$-\frac{3}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	3	-2

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+=3$ then

$$
\begin{aligned}
d &= \alpha_\infty^+-\left(\alpha_{c_1}^++\alpha_{c_2}^-+\alpha_{c_3}^-\right) \\
&= 3-(3) \\
&= 0
\end{aligned}
$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$
\omega=\sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c+\frac{\alpha_c^{s(c)}}{x-c}\right)+s(\infty)[\sqrt{r}]_\infty
$$

Substituting the above values in the above results in

$$
\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{-}}{x-c_2}\right) + \left((-)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^{-}}{x-c_3}\right) + (+)[\sqrt{r}]_{\infty} \\
&= \frac{9}{2x} - \frac{3}{4\,(x-i)} - \frac{3}{4\,(x+i)} + (0) \\
&= \frac{9}{2x} - \frac{3}{4\,(x-i)} - \frac{3}{4\,(x+i)} \\
&= \frac{9}{2x} - \frac{3x}{2x^2+2}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{9}{2x} - \frac{3}{4\,(x-i)} - \frac{3}{4\,(x+i)}\right)(0) + \left(\left(-\frac{9}{2x^2} + \frac{3}{4\,(x-i)^2} + \frac{3}{4\,(x+i)^2}\right) + \left(\frac{9}{2x} - \frac{3}{4\,(x-i)} - 4(\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= e^{\int \left(\frac{9}{2x} - \frac{3}{4(x-i)} - \frac{3}{4(x+i)}\right) dx} \\
&= \frac{x^{9/2}}{\left(x^2+1\right)^{3/4}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{10x^3+3x}{x^4+x^2} \, dx} \\
&= z_1 e^{-\frac{3\ln(x)}{2} - \frac{7\ln\left(x^2+1\right)}{4}} \\
&= z_1 \left(\frac{1}{x^{3/2}\left(x^2+1\right)^{7/4}}\right)
\end{aligned}
$$

Which simplifies to

$$y_1 = \frac{x^3}{\left(x^2+1\right)^{5/2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{10x^3+3x}{x^4+x^2} dx}}{(y_1)^2} dx \\
&= y_1 \int \frac{e^{-3\ln(x)-\frac{7\ln(x^2+1)}{2}}}{(y_1)^2} dx \\
&= y_1 \left(-\frac{(x^2+1)^{5/2}}{8x^8} + \frac{(x^2+1)^{5/2}}{16x^6} - \frac{(x^2+1)^{5/2}}{64x^4} - \frac{(x^2+1)^{5/2}}{128x^2} + \frac{(x^2+1)^{3/2}}{128} + \frac{3\sqrt{x^2+1}}{128} \right. \\
&\quad \left. - \frac{3\,\mathrm{arctanh}\left(\frac{1}{\sqrt{x^2+1}}\right)}{128} \right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{x^3}{(x^2+1)^{5/2}} \right) \\
&\quad + c_2 \left(\frac{x^3}{(x^2+1)^{5/2}} \left(-\frac{(x^2+1)^{5/2}}{8x^8} + \frac{(x^2+1)^{5/2}}{16x^6} - \frac{(x^2+1)^{5/2}}{64x^4} - \frac{(x^2+1)^{5/2}}{128x^2} + \frac{(x^2+1)^{3/2}}{128} + \frac{3\sqrt{x^2+1}}{128} - \frac{3\,\mathrm{ar}}{} \right. \right.
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2(x^2+1)\left(\frac{d^2}{dx^2}y(x)\right) + x(10x^2+3)\left(\frac{d}{dx}y(x)\right) - (-14x^2+15)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{(14x^2-15)y(x)}{x^2(x^2+1)} - \frac{(10x^2+3)\left(\frac{d}{dx}y(x)\right)}{x(x^2+1)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x) + \frac{(10x^2+3)\left(\frac{d}{dx}y(x)\right)}{x(x^2+1)} + \frac{(14x^2-15)y(x)}{x^2(x^2+1)} = 0$

□ Check to see if x_0 is a regular singular point

  - Define functions

    $\left[P_2(x) = \frac{10x^2+3}{x(x^2+1)}, P_3(x) = \frac{14x^2-15}{x^2(x^2+1)}\right]$

  - $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left.(x \cdot P_2(x))\right|_{x=0} = 3$

  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $\left.(x^2 \cdot P_3(x))\right|_{x=0} = -15$

  - $x = 0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = 0$

- Multiply by denominators
$x^2(x^2+1)\left(\frac{d^2}{dx^2}y(x)\right)+x(10x^2+3)\left(\frac{d}{dx}y(x)\right)+(14x^2-15)\,y(x)=0$
- Assume series solution for $y(x)$
$y(x)=\sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions
  - Convert $x^m\cdot y(x)$ to series expansion for $m=0..2$
  $x^m\cdot y(x)=\sum_{k=0}^{\infty} a_k x^{k+r+m}$
  - Shift index using $k->k-m$
  $x^m\cdot y(x)=\sum_{k=m}^{\infty} a_{k-m} x^{k+r}$
  - Convert $x^m\cdot\left(\frac{d}{dx}y(x)\right)$ to series expansion for $m=1..3$
  $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$
  - Shift index using $k->k+1-m$
  $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$
  - Convert $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m=2..4$
  $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r-2+m}$
  - Shift index using $k->k+2-m$
  $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$

  Rewrite ODE with series expansions
  $a_0(5+r)\,(-3+r)\,x^r+a_1(6+r)\,(-2+r)\,x^{1+r}+\left(\sum_{k=2}^{\infty}(a_k(k+r+5)\,(k+r-3)+a_{k-2}(k+r-$

- $a_0$cannot be 0 by assumption, giving the indicial equation
$(5+r)\,(-3+r)=0$
- Values of r that satisfy the indicial equation
$r\in\{-5,3\}$
- Each term must be 0
$a_1(6+r)\,(-2+r)=0$
- Solve for the dependent coefficient(s)
$a_1=0$
- Each term in the series must be 0, giving the recursion relation
$(k+r+5)\,(a_k(k+r-3)+a_{k-2}(k+r))=0$
- Shift index using $k->k+2$
$(k+r+7)\,(a_{k+2}(k+r-1)+a_k(k+r+2))=0$
- Recursion relation that defines series solution to ODE
$a_{k+2}=-\frac{a_k(k+r+2)}{k+r-1}$
- Recursion relation for $r=-5$
$a_{k+2}=-\frac{a_k(k-3)}{k-6}$
- Series not valid for $r=-5$, division by 0 in the recursion relation at $k=6$
$a_{k+2}=-\frac{a_k(k-3)}{k-6}$
- Recursion relation for $r=3$
$a_{k+2}=-\frac{a_k(k+5)}{k+2}$
- Solution for $r=3$

$$\left[y(x)=\sum_{k=0}^{\infty} a_k x^{k+3}, a_{k+2}=-\frac{a_k(k+5)}{k+2}, a_1=0\right]$$

2.1.167 Problem 169

Internal problem ID [9339]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 169
Date solved : `Monday, January 27, 2025 at 06:01:39 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2\left(-2x^2+1\right)y''+x\left(-13x^2+7\right)y'-14x^2y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.294 (sec)

Writing the ode as

$$\left(-2x^4+x^2\right)y''+\left(-13x^3+7x\right)y'-14x^2y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=-2x^4+x^2\\ B&=-13x^3+7x\\ C&=-14x^2\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned}r&=\frac{s}{t}\\ &=\frac{2AB'-2BA'+B^2-4AC}{4A^2}\end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{5x^4-68x^2+35}{4\left(2x^3-x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned}s&=5x^4-68x^2+35\\ t&=4\left(2x^3-x\right)^2\end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{5x^4-68x^2+35}{4\left(2x^3-x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.318: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 4 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(2x^3 - x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = \frac{\sqrt{2}}{2}$ of order 2. There is a pole at $x = -\frac{\sqrt{2}}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{9}{64\left(x - \frac{\sqrt{2}}{2}\right)^2} + \frac{9}{64\left(x + \frac{\sqrt{2}}{2}\right)^2} - \frac{279\sqrt{2}}{64\left(x - \frac{\sqrt{2}}{2}\right)} + \frac{279\sqrt{2}}{64\left(x + \frac{\sqrt{2}}{2}\right)} + \frac{35}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{35}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{5}{2} \end{aligned}$$

For the pole at $x = \frac{\sqrt{2}}{2}$ let b be the coefficient of $\frac{1}{\left(x-\frac{\sqrt{2}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{9}{64}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{9}{8} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{8}
\end{aligned}
$$

For the pole at $x = -\frac{\sqrt{2}}{2}$ let b be the coefficient of $\frac{1}{\left(x+\frac{\sqrt{2}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{9}{64}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{9}{8} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{8}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = \frac{5x^4 - 68x^2 + 35}{4\left(2x^3 - x\right)^2}
$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{5}{16}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{4} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{4}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{5x^4 - 68x^2 + 35}{4\left(2x^3 - x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{7}{2}$	$-\frac{5}{2}$
$\frac{\sqrt{2}}{2}$	2	0	$\frac{9}{8}$	$-\frac{1}{8}$
$-\frac{\sqrt{2}}{2}$	2	0	$\frac{9}{8}$	$-\frac{1}{8}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{5}{4}$	$-\frac{1}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -\frac{1}{4}$ then

$$
\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^+ + \alpha_{c_3}^+\right) \\
&= -\frac{1}{4} - \left(-\frac{1}{4}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x-c_2} \right) + \left((+)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^+}{x-c_3} \right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{5}{2x} + \frac{9}{8\left(x-\frac{\sqrt{2}}{2}\right)} + \frac{9}{8\left(x+\frac{\sqrt{2}}{2}\right)} + (-)(0) \\
&= -\frac{5}{2x} + \frac{9}{8\left(x-\frac{\sqrt{2}}{2}\right)} + \frac{9}{8\left(x+\frac{\sqrt{2}}{2}\right)} \\
&= \frac{-x^2+5}{4x^3-2x}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{5}{2x} + \frac{9}{8\left(x-\frac{\sqrt{2}}{2}\right)} + \frac{9}{8\left(x+\frac{\sqrt{2}}{2}\right)} \right)(0) + \left(\left(\frac{5}{2x^2} - \frac{9}{8\left(x-\frac{\sqrt{2}}{2}\right)^2} - \frac{9}{8\left(x+\frac{\sqrt{2}}{2}\right)^2} \right) + \left(-\frac{5}{2x} + \frac{}{8} \right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx} \\
&= e^{\int \left(-\frac{5}{2x} + \frac{9}{8\left(x-\frac{\sqrt{2}}{2}\right)} + \frac{9}{8\left(x+\frac{\sqrt{2}}{2}\right)} \right) dx} \\
&= \frac{\left(2x+\sqrt{2}\right)^{9/8} \left(2x-\sqrt{2}\right)^{9/8}}{x^{5/2}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{-13x^3+7x}{-2x^4+x^2}\, dx} \\
&= z_1 e^{\frac{\ln\left(2x^2-1\right)}{8} - \frac{7\ln(x)}{2}} \\
&= z_1 \left(\frac{\left(2x^2-1\right)^{1/8}}{x^{7/2}} \right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{2\left(2x^2-1\right)^{5/4} 2^{1/8}}{x^6}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-13x^3+7x}{-2x^4+x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{\frac{\ln(2x^2-1)}{4}-7\ln(x)}}{(y_1)^2}\,dx \\
&= y_1 \left(\frac{(5x^4-20x^2+8)\,x^7 \mathrm{e}^{\frac{\ln(2x^2-1)}{4}-7\ln(x)} 2^{3/4}}{120\,(2x^2-1)^{3/2}}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{2(2x^2-1)^{5/4}\,2^{1/8}}{x^6}\right) \\
&\quad + c_2 \left(\frac{2(2x^2-1)^{5/4}\,2^{1/8}}{x^6}\left(\frac{(5x^4-20x^2+8)\,x^7 \mathrm{e}^{\frac{\ln(2x^2-1)}{4}-7\ln(x)} 2^{3/4}}{120\,(2x^2-1)^{3/2}}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

  - $x \cdot P_2(x)$ is analytic at $x = 0$
    $\left.(x \cdot P_2(x))\right|_{x=0} = 7$
  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$
    $\left.(x^2 \cdot P_3(x))\right|_{x=0} = 0$
  - $x = 0$is a regular singular point
    Check to see if x_0 is a regular singular point

$x_0 = 0$

- Multiply by denominators

$x(2x^2-1)\left(\frac{d^2}{dx^2}y(x)\right)+(13x^2-7)\left(\frac{d}{dx}y(x)\right)+14xy(x)=0$

- Assume series solution for $y(x)$

$y(x)=\sum_{k=0}^{\infty}a_k x^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $x \cdot y(x)$ to series expansion

  $x \cdot y(x)=\sum_{k=0}^{\infty}a_k x^{k+r+1}$

  ◦ Shift index using $k->k-1$

  $x \cdot y(x)=\sum_{k=1}^{\infty}a_{k-1}x^{k+r}$

  ◦ Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m=0..2$

  $x^m \cdot \left(\frac{d}{dx}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,x^{k+r-1+m}$

  ◦ Shift index using $k->k+1-m$

  $x^m \cdot \left(\frac{d}{dx}y(x)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,x^{k+r}$

  ◦ Convert $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m=1..3$

  $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,x^{k+r-2+m}$

  ◦ Shift index using $k->k+2-m$

  $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=-2+m}^{\infty}a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$

  Rewrite ODE with series expansions

  $-a_0r(6+r)\,x^{-1+r}-a_1(1+r)\,(7+r)\,x^r+\left(\sum_{k=1}^{\infty}(-a_{k+1}(k+r+1)\,(k+7+r)+a_{k-1}(2k+5+2r)\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$-r(6+r)=0$

- Values of r that satisfy the indicial equation

$r\in\{-6,0\}$

- Each term must be 0

$-a_1(1+r)\,(7+r)=0$

- Each term in the series must be 0, giving the recursion relation

$2(k+r+1)\left(\left(k+r+\frac{5}{2}\right)a_{k-1}-\frac{a_{k+1}(k+7+r)}{2}\right)=0$

- Shift index using $k->k+1$

$2(k+r+2)\left(\left(k+\frac{7}{2}+r\right)a_k-\frac{a_{k+2}(k+8+r)}{2}\right)=0$

- Recursion relation that defines series solution to ODE

$a_{k+2}=\frac{(2k+2r+7)a_k}{k+8+r}$

- Recursion relation for $r=-6$

$a_{k+2}=\frac{(2k-5)a_k}{k+2}$

- Solution for $r=-6$

$\left[y(x)=\sum_{k=0}^{\infty}a_k x^{k-6}, a_{k+2}=\frac{(2k-5)a_k}{k+2}, 5a_1=0\right]$

- Recursion relation for $r=0$

$a_{k+2}=\frac{(2k+7)a_k}{k+8}$

- Solution for $r = 0$
$$\left[y(x) = \sum_{k=0}^{\infty} a_k x^k, a_{k+2} = \frac{(2k+7)a_k}{k+8}, -7a_1 = 0\right]$$
- Combine solutions and rename parameters
$$\left[y(x) = \left(\sum_{k=0}^{\infty} a_k x^{k-6}\right) + \left(\sum_{k=0}^{\infty} b_k x^k\right), a_{k+2} = \frac{(2k-5)a_k}{k+2}, 5a_1 = 0, b_{k+2} = \frac{(2k+7)b_k}{k+8}, -7b_1 = 0\right]$$

2.1.168 Problem 170

Internal problem ID [9340]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 170
Date solved : `Monday, January 27, 2025 at 06:01:40 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$4x^2(1+x)\,y''+4x(1+2x)\,y'-(1+3x)\,y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.215 (sec)

Writing the ode as

$$\left(4x^3+4x^2\right)y''+\left(8x^2+4x\right)y'+(-3x-1)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A&=4x^3+4x^2\\ B&=8x^2+4x\\ C&=-3x-1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r&=\frac{s}{t} \\ &=\frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{3x+4}{4x\left(1+x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s&=3x+4\\ t&=4x(1+x)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{3x+4}{4x\left(1+x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.320: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 3 - 1 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x(1+x)^2$. There is a pole at $x = 0$ of order 1. There is a pole at $x = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 1. For the pole at $x = 0$ of order 1 then

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= 1 \\ \alpha_c^- &= 1 \end{aligned}$$

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{1+x} + \frac{1}{x} - \frac{1}{4\,(1+x)^2}$$

For the pole at $x = -1$ let b be the coefficient of $\frac{1}{(1+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{3x+4}{4x(1+x)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{3}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{3x+4}{4x(1+x)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	1	0	0	1
-1	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{3}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^- + \alpha_{c_2}^+\right) \\
&= \frac{3}{2} - \left(\frac{3}{2}\right) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x-c_2} \right) + (+)[\sqrt{r}]_\infty \\
&= \frac{1}{x} + \frac{1}{2+2x} + (0) \\
&= \frac{1}{x} + \frac{1}{2+2x} \\
&= \frac{1}{x} + \frac{1}{2+2x}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{x} + \frac{1}{2+2x}\right)(0) + \left(\left(-\frac{1}{x^2} - \frac{1}{2(1+x)^2}\right) + \left(\frac{1}{x} + \frac{1}{2+2x}\right)^2 - \left(\frac{3x+4}{4x(1+x)^2}\right)\right) = 0$$
$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= pe^{\int \omega \, dx} \\ &= e^{\int \left(\frac{1}{x} + \frac{1}{2+2x}\right) dx} \\ &= \sqrt{1+x}\, x \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{8x^2+4x}{4x^3+4x^2}\, dx} \\ &= z_1 e^{-\frac{\ln(x(1+x))}{2}} \\ &= z_1 \left(\frac{1}{\sqrt{x(1+x)}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{\sqrt{1+x}\, x}{\sqrt{x(1+x)}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{8x^2+4x}{4x^3+4x^2}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-\ln(x(1+x))}}{(y_1)^2}\, dx \\ &= y_1 \left(\ln(1+x) - \frac{1}{x} - \ln(x)\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\frac{\sqrt{1+x}\, x}{\sqrt{x(1+x)}}\right) + c_2 \left(\frac{\sqrt{1+x}\, x}{\sqrt{x(1+x)}}\left(\ln(1+x) - \frac{1}{x} - \ln(x)\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$4x^2(x+1)\left(\frac{d^2}{dx^2}y(x)\right)+4x(2x+1)\left(\frac{d}{dx}y(x)\right)-(3x+1)\,y(x)=0$

  $4x^2(x+1)\left(\frac{d^2}{dx^2}y(x)\right)+4x(2x+1)\left(\frac{d}{dx}y(x)\right)+(-3x-1)\,y(x)=0$
- Change variables using $x=u-1$ so that the regular singular point is at $u=0$

  $(4u^3-8u^2+4u)\left(\frac{d^2}{du^2}y(u)\right)+(8u^2-12u+4)\left(\frac{d}{du}y(u)\right)+(-3u+2)\,y(u)=0$
- Assume series solution for $y(u)$

  $y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

□ Rewrite ODE with series expansions

- ◦ Convert $u^m\cdot y(u)$ to series expansion for $m=0..1$

  $u^m\cdot y(u)=\sum_{k=0}^{\infty}a_k u^{k+r+m}$
- ◦ Shift index using $k->k-m$

  $u^m\cdot y(u)=\sum_{k=m}^{\infty}a_{k-m}u^{k+r}$
- ◦ Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..2$

  $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,u^{k+r-1+m}$
- ◦ Shift index using $k->k+1-m$

  $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,u^{k+r}$
- ◦ Convert $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m=1..3$

  $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)(k+r-1)\,u^{k+r-2+m}$
- ◦ Shift index using $k->k+2-m$

$$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\,u^{k+r}$$

Rewrite ODE with series expansions

$$4a_0r^2u^{-1+r} + \left(4a_1(1+r)^2 - 2a_0(4r^2+2r-1)\right)u^r + \left(\sum_{k=1}^{\infty}\left(4a_{k+1}(k+1+r)^2 - 2a_k(4k^2+8kr\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $4r^2 = 0$
- Values of r that satisfy the indicial equation
  $r = 0$
- Each term must be 0
  $4a_1(1+r)^2 - 2a_0(4r^2+2r-1) = 0$
- Each term in the series must be 0, giving the recursion relation
  $(4k^2-4k-3)\,a_{k-1} + (-8k^2-4k+2)\,a_k + 4a_{k+1}(k+1)^2 = 0$
- Shift index using $k- >k+1$
  $\left(4(k+1)^2-4k-7\right)a_k + \left(-8(k+1)^2-4k-2\right)a_{k+1} + 4a_{k+2}(k+2)^2 = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+2} = -\frac{4k^2a_k-8k^2a_{k+1}+4ka_k-20ka_{k+1}-3a_k-10a_{k+1}}{4(k+2)^2}$
- Recursion relation for $r = 0$
  $a_{k+2} = -\frac{4k^2a_k-8k^2a_{k+1}+4ka_k-20ka_{k+1}-3a_k-10a_{k+1}}{4(k+2)^2}$
- Solution for $r = 0$
  $\left[y(u) = \sum_{k=0}^{\infty} a_ku^k, a_{k+2} = -\frac{4k^2a_k-8k^2a_{k+1}+4ka_k-20ka_{k+1}-3a_k-10a_{k+1}}{4(k+2)^2}, 4a_1+2a_0 = 0\right]$
- Revert the change of variables $u = x+1$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k(x+1)^k, a_{k+2} = -\frac{4k^2a_k-8k^2a_{k+1}+4ka_k-20ka_{k+1}-3a_k-10a_{k+1}}{4(k+2)^2}, 4a_1+2a_0 = 0\right]$

2.1.169 Problem 171

Internal problem ID [9341]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 171
Date solved : `Monday, January 27, 2025 at 06:01:41 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$2x^2(2+3x)\,y''+x(4+21x)\,y'-(1-9x)\,y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.220 (sec)

Writing the ode as

$$\left(6x^3+4x^2\right)y''+\left(21x^2+4x\right)y'+(9x-1)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A&=6x^3+4x^2\\ B&=21x^2+4x\\ C&=9x-1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r&=\frac{s}{t} \\ &=\frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{-27x-48}{16x\,(2+3x)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s&=-27x-48\\ t&=16x(2+3x)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{-27x-48}{16x\,(2+3x)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.322: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 3 - 1 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16x(2+3x)^2$. There is a pole at $x = 0$ of order 1. There is a pole at $x = -\frac{2}{3}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 1. For the pole at $x = 0$ of order 1 then

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= 1 \\ \alpha_c^- &= 1 \end{aligned}$$

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{3}{4x} + \frac{5}{16\left(x + \frac{2}{3}\right)^2} + \frac{3}{4\left(x + \frac{2}{3}\right)}$$

For the pole at $x = -\frac{2}{3}$ let b be the coefficient of $\frac{1}{\left(x+\frac{2}{3}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{5}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{4} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{-27x - 48}{16x(2+3x)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{3}{16}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{4} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{4}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{-27x - 48}{16x(2+3x)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	1	0	0	1
$-\frac{2}{3}$	2	0	$\frac{5}{4}$	$-\frac{1}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{3}{4}$	$\frac{1}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{3}{4}$ then

$$\begin{aligned}
d &= \alpha_\infty^+ - (\alpha_{c_1}^- + \alpha_{c_2}^-) \\
&= \frac{3}{4} - \left(\frac{3}{4}\right) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2}\right) + (+)[\sqrt{r}]_\infty \\
&= \frac{1}{x} - \frac{1}{4\left(x+\frac{2}{3}\right)} + (0) \\
&= \frac{1}{x} - \frac{1}{4\left(x+\frac{2}{3}\right)} \\
&= \frac{8+9x}{12x^2+8x}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{x} - \frac{1}{4\left(x+\frac{2}{3}\right)}\right)(0) + \left(\left(-\frac{1}{x^2} + \frac{1}{4\left(x+\frac{2}{3}\right)^2}\right) + \left(\frac{1}{x} - \frac{1}{4\left(x+\frac{2}{3}\right)}\right)^2 - \left(\frac{-27x-48}{16x\,(2+3x)^2}\right)\right) = 0$$

$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega\, dx} \\ &= \mathrm{e}^{\int \left(\frac{1}{x} - \frac{1}{4\left(x+\frac{2}{3}\right)}\right) dx} \\ &= \frac{x}{(2+3x)^{1/4}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{21x^2+4x}{6x^3+4x^2}\, dx} \\ &= z_1 e^{-\frac{5\ln(2+3x)}{4} - \frac{\ln(x)}{2}} \\ &= z_1 \left(\frac{1}{(2+3x)^{5/4}\sqrt{x}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{\sqrt{x}}{(2+3x)^{3/2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{21x^2+4x}{6x^3+4x^2}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-\frac{5\ln(2+3x)}{2} - \ln(x)}}{(y_1)^2}\, dx \\ &= y_1 \left(-\frac{\sqrt{2+3x}}{x} - \frac{3\sqrt{2}\,\operatorname{arctanh}\left(\frac{\sqrt{2+3x}\,\sqrt{2}}{2}\right)}{2}\right) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{\sqrt{x}}{(2+3x)^{3/2}}\right) + c_2\left(\frac{\sqrt{x}}{(2+3x)^{3/2}}\left(-\frac{\sqrt{2+3x}}{x} - \frac{3\sqrt{2}\,\operatorname{arctanh}\left(\frac{\sqrt{2+3x}\,\sqrt{2}}{2}\right)}{2}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$2x^2(3x+2)\left(\frac{d^2}{dx^2}y(x)\right) + x(4+21x)\left(\frac{d}{dx}y(x)\right) - (1-9x)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{(-1+9x)y(x)}{2(3x+2)x^2} - \frac{(4+21x)\left(\frac{d}{dx}y(x)\right)}{2x(3x+2)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x) + \frac{(4+21x)\left(\frac{d}{dx}y(x)\right)}{2x(3x+2)} + \frac{(-1+9x)y(x)}{2(3x+2)x^2} = 0$

□ Check to see if x_0 is a regular singular point

  - Define functions

    $\left[P_2(x) = \frac{4+21x}{2x(3x+2)}, P_3(x) = \frac{-1+9x}{2(3x+2)x^2}\right]$

  - $x \cdot P_2(x)$ is analytic at $x=0$

    $\left.(x \cdot P_2(x))\right|_{x=0} = 1$

  - $x^2 \cdot P_3(x)$ is analytic at $x=0$

    $\left.(x^2 \cdot P_3(x))\right|_{x=0} = -\frac{1}{4}$

  - $x = 0$is a regular singular point

    Check to see if x_0 is a regular singular point

    $x_0 = 0$

- Multiply by denominators

  $2x^2(3x+2)\left(\frac{d^2}{dx^2}y(x)\right) + x(4+21x)\left(\frac{d}{dx}y(x)\right) + (-1+9x)\,y(x) = 0$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

  - Convert $x^m \cdot y(x)$ to series expansion for $m = 0..1$

    $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

  - Shift index using $k- >k-m$

    $x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

  - Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m = 1..2$

    $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r-1+m}$

  - Shift index using $k- >k+1-m$

    $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$

- Convert $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m = 2..3$

  $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, x^{k+r-2+m}$
- Shift index using $k->k+2-m$

  $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(1+2r)(-1+2r)\, x^r + \left(\sum_{k=1}^{\infty} (a_k(2k+2r+1)(2k+2r-1) + 3a_{k-1}(2k+2r+1)(k+r))\, x^{k+r}\right)$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(1+2r)(-1+2r) = 0$
- Values of r that satisfy the indicial equation

  $r \in \left\{-\frac{1}{2}, \frac{1}{2}\right\}$
- Each term in the series must be 0, giving the recursion relation

  $4\left(\left(k+r-\frac{1}{2}\right)a_k + \frac{3a_{k-1}(k+r)}{2}\right)\left(k+r+\frac{1}{2}\right) = 0$
- Shift index using $k->k+1$

  $4\left(\left(k+r+\frac{1}{2}\right)a_{k+1} + \frac{3a_k(k+r+1)}{2}\right)\left(k+\frac{3}{2}+r\right) = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+1} = -\frac{3a_k(k+r+1)}{2k+2r+1}$
- Recursion relation for $r = -\frac{1}{2}$

  $a_{k+1} = -\frac{3a_k\left(k+\frac{1}{2}\right)}{2k}$
- Solution for $r = -\frac{1}{2}$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k-\frac{1}{2}}, a_{k+1} = -\frac{3a_k\left(k+\frac{1}{2}\right)}{2k}\right]$
- Recursion relation for $r = \frac{1}{2}$

  $a_{k+1} = -\frac{3a_k\left(k+\frac{3}{2}\right)}{2k+2}$
- Solution for $r = \frac{1}{2}$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}, a_{k+1} = -\frac{3a_k\left(k+\frac{3}{2}\right)}{2k+2}\right]$
- Combine solutions and rename parameters

  $\left[y(x) = \left(\sum_{k=0}^{\infty} a_k x^{k-\frac{1}{2}}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{2}}\right), a_{k+1} = -\frac{3a_k\left(k+\frac{1}{2}\right)}{2k}, b_{k+1} = -\frac{3b_k\left(k+\frac{3}{2}\right)}{2k+2}\right]$

2.1.170 Problem 172

Internal problem ID [9342]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 172
Date solved : Monday, January 27, 2025 at 06:01:41 PM
CAS classification : [[_2nd_order, _with_linear_symmetries]]

Solve

$$x^2y'' + x(2+x)\,y' - (2-3x)\,y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.233 (sec)

Writing the ode as

$$x^2y'' + \left(x^2+2x\right)y' + (3x-2)\,y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= x^2+2x \\ C &= 3x-2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2-8x+8}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2-8x+8 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2-8x+8}{4x^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.324: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} - \frac{2}{x} + \frac{2}{x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -1 \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} - \frac{2}{x} - \frac{2}{x^2} - \frac{8}{x^3} - \frac{36}{x^4} - \frac{176}{x^5} - \frac{912}{x^6} - \frac{4928}{x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 - 8x + 8}{4x^2} \\ &= Q + \frac{R}{4x^2} \\ &= \left(\frac{1}{4}\right) + \left(\frac{-8x + 8}{4x^2}\right) \\ &= \frac{1}{4} + \frac{-8x + 8}{4x^2} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is -8. Dividing this by leading coefficient in t which is 4 gives -2. Now b can be found.

$$\begin{aligned} b &= (-2) - (0) \\ &= -2 \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-2}{\frac{1}{2}} - 0\right) &= -2 \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-2}{\frac{1}{2}} - 0\right) &= 2 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2 - 8x + 8}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	2	-1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	-2	2

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 2$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^+\right) \\ &= 2 - (2) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{2}{x} + (-)\left(\frac{1}{2}\right) \\ &= \frac{2}{x} - \frac{1}{2} \\ &= -\frac{x-4}{2x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(\frac{2}{x} - \frac{1}{2}\right)(0) + \left(\left(-\frac{2}{x^2}\right) + \left(\frac{2}{x} - \frac{1}{2}\right)^2 - \left(\frac{x^2-8x+8}{4x^2}\right)\right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= e^{\int \left(\frac{2}{x} - \frac{1}{2}\right) dx} \\ &= x^2 e^{-\frac{x}{2}} \end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{x^2+2x}{x^2}\,dx} \\
&= z_1 e^{-\frac{x}{2}-\ln(x)} \\
&= z_1 \left(\frac{e^{-\frac{x}{2}}}{x}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = x\,e^{-x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x^2+2x}{x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-x-2\ln(x)}}{(y_1)^2}\,dx \\
&= y_1 \left(-\frac{e^x}{3x^3} - \frac{e^x}{6x^2} - \frac{e^x}{6x} - \frac{\mathrm{Ei}_1(-x)}{6}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(x\,e^{-x}\right) + c_2 \left(x\,e^{-x}\left(-\frac{e^x}{3x^3} - \frac{e^x}{6x^2} - \frac{e^x}{6x} - \frac{\mathrm{Ei}_1(-x)}{6}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2\left(\frac{d^2}{dx^2}y(x)\right) + x(x+2)\left(\frac{d}{dx}y(x)\right) - (-3x+2)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{(3x-2)y(x)}{x^2} - \frac{(x+2)\left(\frac{d}{dx}y(x)\right)}{x}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x) + \frac{(x+2)\left(\frac{d}{dx}y(x)\right)}{x} + \frac{(3x-2)y(x)}{x^2} = 0$

- ☐ Check to see if $x_0 = 0$ is a regular singular point
  - Define functions

    $\left[P_2(x) = \frac{x+2}{x}, P_3(x) = \frac{3x-2}{x^2}\right]$

  - $x \cdot P_2(x)$ is analytic at $x = 0$

$(x \cdot P_2(x))\bigg|_{x=0} = 2$

- ○ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $(x^2 \cdot P_3(x))\bigg|_{x=0} = -2$

- ○ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $x^2\left(\frac{d^2}{dx^2}y(x)\right) + x(x+2)\left(\frac{d}{dx}y(x)\right) + (3x-2)\,y(x) = 0$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

- ○ Convert $x^m \cdot y(x)$ to series expansion for $m = 0..1$

  $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- ○ Shift index using $k- > k - m$

  $x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- ○ Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m = 1..2$

  $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$

- ○ Shift index using $k- > k + 1 - m$

  $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$

- ○ Convert $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

  $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(2+r)\,(-1+r)\,x^r + \left(\sum_{k=1}^{\infty} \left(a_k(k+r+2)\,(k+r-1) + a_{k-1}(k+r+2)\right) x^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(2+r)\,(-1+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{-2, 1\}$

- Each term in the series must be 0, giving the recursion relation

  $(k+r+2)\,(a_k(k+r-1) + a_{k-1}) = 0$

- Shift index using $k- > k + 1$

  $(k+r+3)\,(a_{k+1}(k+r) + a_k) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+1} = -\frac{a_k}{k+r}$

- Recursion relation for $r = -2$

  $a_{k+1} = -\frac{a_k}{k-2}$

- Series not valid for $r = -2$, division by 0 in the recursion relation at $k = 2$

  $a_{k+1} = -\frac{a_k}{k-2}$

- Recursion relation for $r = 1$

  $a_{k+1} = -\frac{a_k}{k+1}$

- Solution for $r = 1$

$$\left[y(x)=\sum_{k=0}^{\infty} a_k x^{k+1}, a_{k+1}=-\frac{a_k}{k+1}\right]$$

2.1.171 Problem 173

Internal problem ID [9343]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 173
Date solved : `Monday, January 27, 2025 at 06:01:42 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$4x^2(1+x)\,y''+4x(3+8x)\,y'-(5-49x)\,y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.226 (sec)

Writing the ode as

$$\left(4x^3+4x^2\right)y''+\left(32x^2+12x\right)y'+(49x-5)\,y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=4x^3+4x^2\\B&=32x^2+12x\\C&=49x-5\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned}r&=\frac{s}{t}\\&=\frac{2AB'-2BA'+B^2-4AC}{4A^2}\end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{-x^2-8x+8}{4\left(x^2+x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned}s&=-x^2-8x+8\\t&=4\left(x^2+x\right)^2\end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{-x^2-8x+8}{4\left(x^2+x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.326: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^2 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{6}{x} + \frac{15}{4\,(1+x)^2} + \frac{6}{1+x} + \frac{2}{x^2}$$

For the pole at $x = -1$ let b be the coefficient of $\frac{1}{(1+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{15}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{2} \end{aligned}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1 \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{-x^2 - 8x + 8}{4\left(x^2 + x\right)^2}$$

Since the $\gcd(s, t) = 1$. This gives $b = -\frac{1}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{-x^2 - 8x + 8}{4\left(x^2 + x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
-1	2	0	$\frac{5}{2}$	$-\frac{3}{2}$
0	2	0	2	-1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^+\right) \\
&= \frac{1}{2} - \left(\frac{1}{2}\right) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x - c_1} \right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x - c_2} \right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{3}{2(1 + x)} + \frac{2}{x} + (-)(0) \\
&= -\frac{3}{2(1 + x)} + \frac{2}{x} \\
&= \frac{x + 4}{2x(1 + x)}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{3}{2(1+x)} + \frac{2}{x}\right)(0) + \left(\left(\frac{3}{2(1+x)^2} - \frac{2}{x^2}\right) + \left(-\frac{3}{2(1+x)} + \frac{2}{x}\right)^2 - \left(\frac{-x^2 - 8x + 8}{4(x^2+x)^2}\right)\right) = 0$$
$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega\, dx} \\ &= \mathrm{e}^{\int \left(-\frac{3}{2(1+x)} + \frac{2}{x}\right) dx} \\ &= \frac{x^2}{(1+x)^{3/2}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2} \frac{32x^2+12x}{4x^3+4x^2}\, dx} \\ &= z_1 e^{-\frac{5\ln(1+x)}{2} - \frac{3\ln(x)}{2}} \\ &= z_1 \left(\frac{1}{(1+x)^{5/2}\, x^{3/2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{\sqrt{x}}{(1+x)^4}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{32x^2+12x}{4x^3+4x^2}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-5\ln(1+x) - 3\ln(x)}}{(y_1)^2}\, dx \\ &= y_1 \left(\ln(x) - \frac{1}{3x^3} - \frac{3}{2x^2} - \frac{3}{x}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\frac{\sqrt{x}}{(1+x)^4}\right) + c_2 \left(\frac{\sqrt{x}}{(1+x)^4} \left(\ln(x) - \frac{1}{3x^3} - \frac{3}{2x^2} - \frac{3}{x}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

2.1.172 Problem 174

Internal problem ID [9344]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 174
Date solved : `Monday, January 27, 2025 at 06:01:42 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2(1+x)\,y''-x(3+10x)\,y'+30xy=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.241 (sec)

Writing the ode as

$$x^2(1+x)\,y''+\left(-10x^2-3x\right)y'+30xy=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=x^2(1+x)\\B&=-10x^2-3x\\C&=30x\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned}r&=\frac{s}{t}\\&=\frac{2AB'-2BA'+B^2-4AC}{4A^2}\end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{-48x+15}{4\left(x^2+x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned}s&=-48x+15\\t&=4\left(x^2+x\right)^2\end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{-48x+15}{4\left(x^2+x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.328: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 1 \\ &= 3 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^2+x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 3 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 3 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{39}{2x} + \frac{15}{4x^2} + \frac{39}{2\,(1+x)} + \frac{63}{4\,(1+x)^2}$$

For the pole at $x = -1$ let b be the coefficient of $\frac{1}{(1+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{63}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{9}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{7}{2} \end{aligned}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{15}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{2} \end{aligned}$$

Since the order of r at ∞ is $3 > 2$ then

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= 0 \\
\alpha_\infty^- &= 1
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{-48x + 15}{4\left(x^2 + x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
-1	2	0	$\frac{9}{2}$	$-\frac{7}{2}$
0	2	0	$\frac{5}{2}$	$-\frac{3}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
3	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = 0$ then

$$\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^- + \alpha_{c_2}^+\right) \\
&= 0 - (-1) \\
&= 1
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x - c_1} \right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x - c_2} \right) + (+)[\sqrt{r}]_\infty \\
&= -\frac{7}{2(1+x)} + \frac{5}{2x} + (0) \\
&= -\frac{7}{2(1+x)} + \frac{5}{2x} \\
&= -\frac{2x - 5}{2x(1+x)}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(-\frac{7}{2(1+x)}+\frac{5}{2x}\right)(1)+\left(\left(\frac{7}{2(1+x)^2}-\frac{5}{2x^2}\right)+\left(-\frac{7}{2(1+x)}+\frac{5}{2x}\right)^2-\left(\frac{-48x+15}{4(x^2+x)^2}\right)\right)=0$$

$$\frac{5+2a_0}{x(1+x)}=0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\left\{a_0=-\frac{5}{2}\right\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x)=x-\frac{5}{2}$$

Therefore the first solution to the ode $z''=rz$ is

$$\begin{aligned}
z_1(x)&=pe^{\int \omega\,dx}\\
&=\left(x-\frac{5}{2}\right)\mathrm{e}^{\int\left(-\frac{7}{2(1+x)}+\frac{5}{2x}\right)dx}\\
&=\left(x-\frac{5}{2}\right)\mathrm{e}^{-\frac{7\ln(1+x)}{2}+\frac{5\ln(x)}{2}}\\
&=\frac{\left(x-\frac{5}{2}\right)x^{5/2}}{(1+x)^{7/2}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1&=z_1e^{\int -\frac{1}{2}\frac{B}{A}\,dx}\\
&=z_1e^{-\int \frac{1}{2}\frac{-10x^2-3x}{x^2(1+x)}\,dx}\\
&=z_1e^{\frac{7\ln(1+x)}{2}+\frac{3\ln(x)}{2}}\\
&=z_1\left((1+x)^{7/2}x^{3/2}\right)
\end{aligned}$$

Which simplifies to

$$y_1=x^5-\frac{5}{2}x^4$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2=y_1\int\frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2&=y_1\int\frac{e^{\int -\frac{-10x^2-3x}{x^2(1+x)}\,dx}}{(y_1)^2}\,dx\\
&=y_1\int\frac{e^{7\ln(1+x)+3\ln(x)}}{(y_1)^2}\,dx\\
&=y_1\left(x-\frac{823543}{6250(2x-5)}-\frac{1}{25x^4}-\frac{52}{125x^3}-\frac{1354}{625x^2}-\frac{27708}{3125x}+12\ln(x)\right)
\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(x^5 - \frac{5}{2}x^4\right) \\
&\quad + c_2\left(x^5 - \frac{5}{2}x^4\left(x - \frac{823543}{6250\,(2x-5)} - \frac{1}{25x^4} - \frac{52}{125x^3} - \frac{1354}{625x^2} - \frac{27708}{3125x} + 12\ln(x)\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2(x+1)\left(\frac{d^2}{dx^2}y(x)\right) - x(10x+3)\left(\frac{d}{dx}y(x)\right) + 30xy(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{30y(x)}{x(x+1)} + \frac{(10x+3)\left(\frac{d}{dx}y(x)\right)}{x(x+1)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x) - \frac{(10x+3)\left(\frac{d}{dx}y(x)\right)}{x(x+1)} + \frac{30y(x)}{x(x+1)} = 0$

□ Check to see if x_0 is a regular singular point

  - Define functions

2.1.173 Problem 175

Internal problem ID [9345]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 175
Date solved : `Monday, January 27, 2025 at 06:01:43 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' + x(1+x)\,y' - 3(3+x)\,y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.285 (sec)

Writing the ode as

$$x^2y'' + \left(x^2+x\right)y' + (-3x-9)\,y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= x^2+x \\ C &= -3x-9 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2+14x+35}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2+14x+35 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2+14x+35}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.330: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} + \frac{7}{2x} + \frac{35}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{35}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{5}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} + \frac{7}{2x} - \frac{7}{2x^2} + \frac{49}{2x^3} - \frac{735}{4x^4} + \frac{5831}{4x^5} - \frac{48363}{4x^6} + \frac{415373}{4x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 + 14x + 35}{4x^2} \\ &= Q + \frac{R}{4x^2} \\ &= \left(\frac{1}{4}\right) + \left(\frac{14x + 35}{4x^2}\right) \\ &= \frac{1}{4} + \frac{14x + 35}{4x^2} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is 14. Dividing this by leading coefficient in t which is 4 gives $\frac{7}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(\frac{7}{2}\right) - (0) \\ &= \frac{7}{2} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) = \frac{1}{2}\left(\frac{\frac{7}{2}}{\frac{1}{2}} - 0\right) = \frac{7}{2} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) = \frac{1}{2}\left(-\frac{\frac{7}{2}}{\frac{1}{2}} - 0\right) = -\frac{7}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2 + 14x + 35}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{7}{2}$	$-\frac{5}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	$\frac{7}{2}$	$-\frac{7}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{7}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^+\right) \\
&= \frac{7}{2} - \left(\frac{7}{2}\right) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1} \right) + (+)[\sqrt{r}]_\infty \\
&= \frac{7}{2x} + \left(\frac{1}{2}\right) \\
&= \frac{1}{2} + \frac{7}{2x} \\
&= \frac{x+7}{2x}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned}
(0) + 2\left(\frac{1}{2} + \frac{7}{2x}\right)(0) + \left(\left(-\frac{7}{2x^2}\right) + \left(\frac{1}{2} + \frac{7}{2x}\right)^2 - \left(\frac{x^2+14x+35}{4x^2}\right) \right) &= 0 \\
0 &= 0
\end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= e^{\int \left(\frac{1}{2} + \frac{7}{2x}\right) dx} \\
&= x^{7/2} e^{\frac{x}{2}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{x^2+x}{x^2}\,dx} \\
&= z_1 e^{-\frac{x}{2}-\frac{\ln(x)}{2}} \\
&= z_1 \left(\frac{e^{-\frac{x}{2}}}{\sqrt{x}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = x^3$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x^2+x}{x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-x-\ln(x)}}{(y_1)^2}\,dx \\
&= y_1 \left(-\frac{e^{-x}}{6x^6}+\frac{e^{-x}}{30x^5}-\frac{e^{-x}}{120x^4}+\frac{e^{-x}}{360x^3}-\frac{e^{-x}}{720x^2}+\frac{e^{-x}}{720x}-\frac{\mathrm{Ei}_1(x)}{720}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(x^3) + c_2\left(x^3\left(-\frac{e^{-x}}{6x^6}+\frac{e^{-x}}{30x^5}-\frac{e^{-x}}{120x^4}+\frac{e^{-x}}{360x^3}-\frac{e^{-x}}{720x^2}+\frac{e^{-x}}{720x}-\frac{\mathrm{Ei}_1(x)}{720}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve
$x^2\left(\frac{d^2}{dx^2}y(x)\right)+x(x+1)\left(\frac{d}{dx}y(x)\right)-3(x+3)\,y(x)=0$

- Highest derivative means the order of the ODE is 2
  $\frac{d^2}{dx^2}y(x)$
- Isolate 2nd derivative
  $\frac{d^2}{dx^2}y(x)=\frac{3(x+3)y(x)}{x^2}-\frac{(x+1)\left(\frac{d}{dx}y(x)\right)}{x}$
- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin
  $\frac{d^2}{dx^2}y(x)+\frac{(x+1)\left(\frac{d}{dx}y(x)\right)}{x}-\frac{3(x+3)y(x)}{x^2}=0$
- □ Check to see if $x_0=0$ is a regular singular point
  - ○ Define functions
    $\left[P_2(x)=\frac{x+1}{x}, P_3(x)=-\frac{3(x+3)}{x^2}\right]$

- $x \cdot P_2(x)$ is analytic at $x = 0$

  $\left(x \cdot P_2(x)\right)\bigg|_{x=0} = 1$
- $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = -9$
- $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $x^2\left(\frac{d^2}{dx^2}y(x)\right) + x(x+1)\left(\frac{d}{dx}y(x)\right) + (-3x-9)\,y(x) = 0$
- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

- Convert $x^m \cdot y(x)$ to series expansion for $m = 0..1$

  $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$
- Shift index using $k- >k - m$

  $x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$
- Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m = 1..2$

  $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$
- Shift index using $k- >k + 1 - m$

  $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$
- Convert $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

  $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(3+r)\,(-3+r)\,x^r + \left(\sum_{k=1}^{\infty} \left(a_k(k+r+3)\,(k+r-3) + a_{k-1}(k-4+r)\right)x^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(3+r)\,(-3+r) = 0$
- Values of r that satisfy the indicial equation

  $r \in \{-3, 3\}$
- Each term in the series must be 0, giving the recursion relation

  $a_k(k+r+3)\,(k+r-3) + a_{k-1}(k-4+r) = 0$
- Shift index using $k- >k + 1$

  $a_{k+1}(k+4+r)\,(k-2+r) + a_k(k+r-3) = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+1} = -\frac{a_k(k+r-3)}{(k+4+r)(k-2+r)}$
- Recursion relation for $r = -3$; series terminates at $k = 6$

  $a_{k+1} = -\frac{a_k(k-6)}{(k+1)(k-5)}$
- Series not valid for $r = -3$, division by 0 in the recursion relation at $k = 5$

  $a_{k+1} = -\frac{a_k(k-6)}{(k+1)(k-5)}$
- Recursion relation for $r = 3$

$a_{k+1} = -\frac{a_k k}{(k+7)(k+1)}$

- Solution for $r = 3$

$$\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+3}, a_{k+1} = -\frac{a_k k}{(k+7)(k+1)}\right]$$

2.1.174 Problem 176

Internal problem ID [9346]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 176
Date solved : Monday, January 27, 2025 at 06:01:44 PM
CAS classification : [[_2nd_order, _with_linear_symmetries]]

Solve

$$x^2(1+2x)\,y''+x(9+13x)\,y'+(7+5x)\,y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.243 (sec)

Writing the ode as

$$\left(2x^3+x^2\right)y''+\left(13x^2+9x\right)y'+(7+5x)\,y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A&=2x^3+x^2\\ B&=13x^2+9x \\ C&=7+5x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r&=\frac{s}{t} \\ &=\frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{77x^2+86x+35}{4\left(2x^2+x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s&=77x^2+86x+35\\ t&=4\left(2x^2+x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{77x^2+86x+35}{4\left(2x^2+x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.332: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(2x^2 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -\frac{1}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{45}{16\left(x + \frac{1}{2}\right)^2} + \frac{27}{2\left(x + \frac{1}{2}\right)} - \frac{27}{2x} + \frac{35}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{35}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{7}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{5}{2} \end{aligned}$$

For the pole at $x = -\frac{1}{2}$ let b be the coefficient of $\frac{1}{\left(x+\frac{1}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{45}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{9}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{5}{4} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{77x^2 + 86x + 35}{4\left(2x^2 + x\right)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{77}{16}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{11}{4} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{7}{4}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{77x^2 + 86x + 35}{4\left(2x^2 + x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{7}{2}$	$-\frac{5}{2}$
$-\frac{1}{2}$	2	0	$\frac{9}{4}$	$-\frac{5}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{11}{4}$	$-\frac{7}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -\frac{7}{4}$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^-\right) \\
&= -\frac{7}{4} - \left(-\frac{15}{4}\right) \\
&= 2
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2}\right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{5}{2x} - \frac{5}{4\left(x+\frac{1}{2}\right)} + (-)\left(0\right) \\
&= -\frac{5}{2x} - \frac{5}{4\left(x+\frac{1}{2}\right)} \\
&= \frac{-5-15x}{4x^2+2x}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 2$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x^2 + a_1 x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(2) + 2\left(-\frac{5}{2x} - \frac{5}{4\left(x+\frac{1}{2}\right)}\right)(2x + a_1) + \left(\left(\frac{5}{2x^2} + \frac{5}{4\left(x+\frac{1}{2}\right)^2}\right) + \left(-\frac{5}{2x} - \frac{5}{4\left(x+\frac{1}{2}\right)}\right)^2 - \left(\frac{77x^2 + 86x}{4\left(2x^2 + \right.}\right.\right.$$

$$\frac{(11a_1 - 8)\, x + 26a_0}{2x^2 + x}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\left\{a_0 = \frac{20}{143}, a_1 = \frac{8}{11}\right\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^2 + \frac{8}{11}x + \frac{20}{143}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \left(x^2 + \frac{8}{11}x + \frac{20}{143}\right) e^{\int \left(-\frac{5}{2x} - \frac{5}{4\left(x+\frac{1}{2}\right)}\right) dx} \\
&= \left(x^2 + \frac{8}{11}x + \frac{20}{143}\right) e^{-\frac{5\ln(1+2x)}{4} - \frac{5\ln(x)}{2}} \\
&= \frac{x^2 + \frac{8}{11}x + \frac{20}{143}}{(1+2x)^{5/4}\, x^{5/2}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{13x^2+9x}{2x^3+x^2}\, dx} \\
&= z_1 e^{\frac{5\ln(1+2x)}{4} - \frac{9\ln(x)}{2}} \\
&= z_1 \left(\frac{(1+2x)^{5/4}}{x^{9/2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{x^2 + \frac{8}{11}x + \frac{20}{143}}{x^7}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{13x^2+9x}{2x^3+x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{\frac{5\ln(1+2x)}{2}-9\ln(x)}}{(y_1)^2}\, dx \\
&= y_1 \left(\frac{143(1+2x)\left(35x^3-45x^2+36x-20\right)x^9 \mathrm{e}^{\frac{5\ln(1+2x)}{2}-9\ln(x)}}{315\left(143x^2+104x+20\right)}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{x^2+\frac{8}{11}x+\frac{20}{143}}{x^7}\right) \\
&\quad + c_2 \left(\frac{x^2+\frac{8}{11}x+\frac{20}{143}}{x^7}\left(\frac{143(1+2x)\left(35x^3-45x^2+36x-20\right)x^9 \mathrm{e}^{\frac{5\ln(1+2x)}{2}-9\ln(x)}}{315\left(143x^2+104x+20\right)}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2(2x+1)\left(\frac{d^2}{dx^2}y(x)\right)+x(9+13x)\left(\frac{d}{dx}y(x)\right)+(7+5x)\,y(x)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x)=-\frac{(7+5x)y(x)}{x^2(2x+1)}-\frac{(9+13x)\left(\frac{d}{dx}y(x)\right)}{x(2x+1)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x)+\frac{(9+13x)\left(\frac{d}{dx}y(x)\right)}{x(2x+1)}+\frac{(7+5x)y(x)}{x^2(2x+1)}=0$

- □ Check to see if x_0 is a regular singular point
  - Define functions

    $\left[P_2(x)=\frac{9+13x}{x(2x+1)}, P_3(x)=\frac{7+5x}{x^2(2x+1)}\right]$

  - $x\cdot P_2(x)$ is analytic at $x=0$

    $\left(x\cdot P_2(x)\right)\Big|_{x=0}=9$

  - $x^2\cdot P_3(x)$ is analytic at $x=0$

    $\left(x^2\cdot P_3(x)\right)\Big|_{x=0}=7$

  - $x=0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=0$

- Multiply by denominators

  $x^2(2x+1)\left(\frac{d^2}{dx^2}y(x)\right)+x(9+13x)\left(\frac{d}{dx}y(x)\right)+(7+5x)\,y(x)=0$

- Assume series solution for $y(x)$

$y(x)=\sum_{k=0}^{\infty} a_k x^{k+r}$

- □ Rewrite ODE with series expansions
  - ○ Convert $x^m \cdot y(x)$ to series expansion for $m=0..1$

    $x^m \cdot y(x)=\sum_{k=0}^{\infty} a_k x^{k+r+m}$
  - ○ Shift index using $k->k-m$

    $x^m \cdot y(x)=\sum_{k=m}^{\infty} a_{k-m} x^{k+r}$
  - ○ Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m=1..2$

    $x^m \cdot \left(\frac{d}{dx}y(x)\right)=\sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1+m}$
  - ○ Shift index using $k->k+1-m$

    $x^m \cdot \left(\frac{d}{dx}y(x)\right)=\sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$
  - ○ Convert $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m=2..3$

    $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-2+m}$
  - ○ Shift index using $k->k+2-m$

    $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(7+r)\,(1+r)\,x^r+\left(\sum_{k=1}^{\infty}\left(a_k(k+r+7)\,(k+r+1)+a_{k-1}(k+4+r)\,(2k-1+2r)\right)x^{k+r}\right)=$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(7+r)\,(1+r)=0$
- Values of r that satisfy the indicial equation

  $r\in\{-7,-1\}$
- Each term in the series must be 0, giving the recursion relation

  $2(k+4+r)\left(k+r-\frac{1}{2}\right)a_{k-1}+a_k(k+r+7)\,(k+r+1)=0$
- Shift index using $k->k+1$

  $2(k+r+5)\left(k+\frac{1}{2}+r\right)a_k+a_{k+1}(k+8+r)\,(k+2+r)=0$
- Recursion relation that defines series solution to ODE

  $a_{k+1}=-\frac{(k+r+5)(2k+2r+1)a_k}{(k+8+r)(k+2+r)}$
- Recursion relation for $r=-7$; series terminates at $k=2$

  $a_{k+1}=-\frac{(k-2)(2k-13)a_k}{(k+1)(k-5)}$
- Apply recursion relation for $k=0$

  $a_1=\frac{26a_0}{5}$
- Apply recursion relation for $k=1$

  $a_2=\frac{11a_1}{8}$
- Express in terms of a_0

  $a_2=\frac{143a_0}{20}$
- Terminating series solution of the ODE for $r=-7$. Use reduction of order to find the second

  $y(x)=a_0\cdot\left(\frac{143}{20}x^2+\frac{26}{5}x+1\right)$
- Recursion relation for $r=-1$

  $a_{k+1}=-\frac{(k+4)(2k-1)a_k}{(k+7)(k+1)}$
- Solution for $r=-1$

$$\left[y(x)=\sum_{k=0}^{\infty} a_k x^{k-1}, a_{k+1}=-\frac{(k+4)(2k-1)a_k}{(k+7)(k+1)}\right]$$

- Combine solutions and rename parameters

$$\left[y(x)=a_0\cdot\left(\frac{143}{20}x^2+\frac{26}{5}x+1\right)+\left(\sum_{k=0}^{\infty} b_k x^{k-1}\right), b_{k+1}=-\frac{(4+k)(2k-1)b_k}{(k+7)(k+1)}\right]$$

Book : Collection of Kovacic problems
Section : section 1
Problem number : 177
Date solved : `Monday, January 27, 2025 at 06:01:44 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$4x^2(1+2x)\,y''-2x(4-x)\,y'-(7+5x)\,y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.200 (sec)

Writing the ode as

$$\left(8x^3+4x^2\right)y''+\left(2x^2-8x\right)y'+(-5x-7)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 8x^3+4x^2\\ B &= 2x^2-8x\\ C &= -5x-7 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t}\\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{33x^2+132x+60}{16\left(2x^2+x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 33x^2+132x+60\\ t &= 16\left(2x^2+x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{33x^2+132x+60}{16\left(2x^2+x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.334: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16(2x^2 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -\frac{1}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{27}{4x} + \frac{15}{4x^2} + \frac{9}{64\left(x + \frac{1}{2}\right)^2} + \frac{27}{4\left(x + \frac{1}{2}\right)}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{15}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{5}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{3}{2} \end{aligned}$$

For the pole at $x = -\frac{1}{2}$ let b be the coefficient of $\frac{1}{\left(x+\frac{1}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{9}{64}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{9}{8} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{1}{8} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{33x^2 + 132x + 60}{16\left(2x^2 + x\right)^2}$$

Since the $\gcd(s, t) = 1$. This gives $b = \frac{33}{64}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{11}{8} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{8}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{33x^2 + 132x + 60}{16\left(2x^2 + x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{5}{2}$	$-\frac{3}{2}$
$-\frac{1}{2}$	2	0	$\frac{9}{8}$	$-\frac{1}{8}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{11}{8}$	$-\frac{3}{8}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -\frac{3}{8}$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^+\right) \\
&= -\frac{3}{8} - \left(-\frac{3}{8}\right) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x-c_2} \right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{3}{2x} + \frac{9}{8\left(x+\frac{1}{2}\right)} + (-)(0) \\
&= -\frac{3}{2x} + \frac{9}{8\left(x+\frac{1}{2}\right)} \\
&= -\frac{3(x+2)}{4x(1+2x)}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p''+2\omega p'+\left(\omega'+\omega^2-r\right)p=0 \tag{1A}$$

Let

$$p(x)=1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(-\frac{3}{2x}+\frac{9}{8\left(x+\frac{1}{2}\right)}\right)(0)+\left(\left(\frac{3}{2x^2}-\frac{9}{8\left(x+\frac{1}{2}\right)^2}\right)+\left(-\frac{3}{2x}+\frac{9}{8\left(x+\frac{1}{2}\right)}\right)^2-\left(\frac{33x^2+132x+60}{16\left(2x^2+x\right)^2}\right)\right.$$
$$0=$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z''=rz$ is

$$\begin{aligned}
z_1(x)&=pe^{\int \omega\,dx}\\
&=\mathrm{e}^{\int\left(-\frac{3}{2x}+\frac{9}{8\left(x+\frac{1}{2}\right)}\right)dx}\\
&=\frac{(1+2x)^{9/8}}{x^{3/2}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1&=z_1e^{\int -\frac{1}{2}\frac{B}{A}\,dx}\\
&=z_1e^{-\int \frac{1}{2}\frac{2x^2-8x}{8x^3+4x^2}\,dx}\\
&=z_1e^{\ln(x)-\frac{9\ln(1+2x)}{8}}\\
&=z_1\left(\frac{x}{(1+2x)^{9/8}}\right)
\end{aligned}$$

Which simplifies to

$$y_1=\frac{1}{\sqrt{x}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2=y_1\int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2&=y_1\int \frac{e^{\int -\frac{2x^2-8x}{8x^3+4x^2}\,dx}}{(y_1)^2}\,dx\\
&=y_1\int \frac{e^{2\ln(x)-\frac{9\ln(1+2x)}{4}}}{(y_1)^2}\,dx\\
&=y_1\left(\frac{2(1+2x)\left(5x^3-10x^2-40x-16\right)\mathrm{e}^{2\ln(x)-\frac{9\ln(1+2x)}{4}}}{35x^2}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y&=c_1y_1+c_2y_2\\
&=c_1\left(\frac{1}{\sqrt{x}}\right)+c_2\left(\frac{1}{\sqrt{x}}\left(\frac{2(1+2x)\left(5x^3-10x^2-40x-16\right)\mathrm{e}^{2\ln(x)-\frac{9\ln(1+2x)}{4}}}{35x^2}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$4x^2(2x+1)\left(\frac{d^2}{dx^2}y(x)\right)-2x(4-x)\left(\frac{d}{dx}y(x)\right)-(7+5x)\,y(x)=0$

- Highest derivative means the order of the ODE is 2

$\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

$\frac{d^2}{dx^2}y(x)=\frac{(7+5x)y(x)}{4x^2(2x+1)}-\frac{(-4+x)\left(\frac{d}{dx}y(x)\right)}{2(2x+1)x}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

$\frac{d^2}{dx^2}y(x)+\frac{(-4+x)\left(\frac{d}{dx}y(x)\right)}{2(2x+1)x}-\frac{(7+5x)y(x)}{4x^2(2x+1)}=0$

□ Check to see if x_0 is a regular singular point

- ◦ Define functions

$\left[P_2(x)=\frac{-4+x}{2(2x+1)x},P_3(x)=-\frac{7+5x}{4x^2(2x+1)}\right]$

- ◦ $x\cdot P_2(x)$ is analytic at $x=0$

$\left.(x\cdot P_2(x))\right|_{x=0}=-2$

- ◦ $x^2\cdot P_3(x)$ is analytic at $x=0$

$\left.(x^2\cdot P_3(x))\right|_{x=0}=-\frac{7}{4}$

- ◦ $x=0$is a regular singular point

Check to see if x_0 is a regular singular point

$x_0=0$

- Multiply by denominators

$4x^2(2x+1)\left(\frac{d^2}{dx^2}y(x)\right)+2x(-4+x)\left(\frac{d}{dx}y(x)\right)+(-5x-7)\,y(x)=0$

- Assume series solution for $y(x)$

$y(x)=\sum_{k=0}^{\infty}a_kx^{k+r}$

□ Rewrite ODE with series expansions

- ◦ Convert $x^m\cdot y(x)$ to series expansion for $m=0..1$

$x^m\cdot y(x)=\sum_{k=0}^{\infty}a_kx^{k+r+m}$

- ◦ Shift index using $k->k-m$

$x^m\cdot y(x)=\sum_{k=m}^{\infty}a_{k-m}x^{k+r}$

- ◦ Convert $x^m\cdot\left(\frac{d}{dx}y(x)\right)$ to series expansion for $m=1..2$

$x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,x^{k+r-1+m}$

- ◦ Shift index using $k->k+1-m$

$x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,x^{k+r}$

- ◦ Convert $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m=2..3$

$x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,x^{k+r-2+m}$

- ◦ Shift index using $k->k+2-m$

$x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=-2+m}^{\infty}a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$

Rewrite ODE with series expansions

$$a_0(1+2r)(-7+2r)x^r + \left(\sum_{k=1}^{\infty} (a_k(2k+2r+1)(2k+2r-7) + a_{k-1}(2k-1+2r)(4k-9+4r))x$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $(1+2r)(-7+2r) = 0$
- Values of r that satisfy the indicial equation
  $r \in \left\{-\frac{1}{2}, \frac{7}{2}\right\}$
- Each term in the series must be 0, giving the recursion relation
  $8\left(k-\frac{9}{4}+r\right)\left(k+r-\frac{1}{2}\right)a_{k-1} + 4a_k\left(k+r+\frac{1}{2}\right)\left(k+r-\frac{7}{2}\right) = 0$
- Shift index using $k- >k+1$
  $8\left(k-\frac{5}{4}+r\right)\left(k+r+\frac{1}{2}\right)a_k + 4a_{k+1}\left(k+\frac{3}{2}+r\right)\left(k-\frac{5}{2}+r\right) = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+1} = -\frac{(4k+4r-5)(2k+2r+1)a_k}{(2k+3+2r)(2k-5+2r)}$
- Recursion relation for $r = -\frac{1}{2}$
  $a_{k+1} = -\frac{2(4k-7)ka_k}{(2k+2)(2k-6)}$
- Series not valid for $r = -\frac{1}{2}$, division by 0 in the recursion relation at $k = 3$
  $a_{k+1} = -\frac{2(4k-7)ka_k}{(2k+2)(2k-6)}$
- Recursion relation for $r = \frac{7}{2}$
  $a_{k+1} = -\frac{(4k+9)(2k+8)a_k}{(2k+10)(2k+2)}$
- Solution for $r = \frac{7}{2}$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+\frac{7}{2}}, a_{k+1} = -\frac{(4k+9)(2k+8)a_k}{(2k+10)(2k+2)}\right]$

2.1.176 Problem 178

Internal problem ID [9348]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 178
Date solved : `Monday, January 27, 2025 at 06:01:45 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$3x^2(3+x)\,y''-x(15+x)\,y'-20y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.225 (sec)

Writing the ode as

$$\left(3x^3+9x^2\right)y''+\left(-x^2-15x\right)y'-20y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=3x^3+9x^2\\B&=-x^2-15x\\C&=-20\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned}r&=\frac{s}{t}\\&=\frac{2AB'-2BA'+B^2-4AC}{4A^2}\end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{7x^2+450x+1215}{36\left(x^2+3x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned}s&=7x^2+450x+1215\\t&=36\left(x^2+3x\right)^2\end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{7x^2+450x+1215}{36\left(x^2+3x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.336: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 36(x^2 + 3x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -3$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{2}{9\,(3 + x)^2} + \frac{15}{4x^2} - \frac{10}{9x} + \frac{10}{9\,(3 + x)}$$

For the pole at $x = -3$ let b be the coefficient of $\frac{1}{(3+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{2}{9}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{2}{3} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{3} \end{aligned}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{15}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{5}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{3}{2} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{7x^2 + 450x + 1215}{36\left(x^2 + 3x\right)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{7}{36}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{6} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{6}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{7x^2 + 450x + 1215}{36\left(x^2 + 3x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
-3	2	0	$\frac{2}{3}$	$\frac{1}{3}$
0	2	0	$\frac{5}{2}$	$-\frac{3}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{7}{6}$	$-\frac{1}{6}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -\frac{1}{6}$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^-\right) \\
&= -\frac{1}{6} - \left(-\frac{7}{6}\right) \\
&= 1
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2} \right) + (-)[\sqrt{r}]_\infty \\
&= \frac{1}{9+3x} - \frac{3}{2x} + (-)(0) \\
&= \frac{1}{9+3x} - \frac{3}{2x} \\
&= -\frac{7x+27}{6x(3+x)}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{9+3x} - \frac{3}{2x}\right)(1) + \left(\left(-\frac{1}{3(3+x)^2} + \frac{3}{2x^2}\right) + \left(\frac{1}{9+3x} - \frac{3}{2x}\right)^2 - \left(\frac{7x^2 + 450x + 1215}{36(x^2+3x)^2}\right)\right) = \frac{-27 + 7a_0}{3x(3+x)} = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\left\{a_0 = \frac{27}{7}\right\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x + \frac{27}{7}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \left(x + \frac{27}{7}\right) e^{\int \left(\frac{1}{9+3x} - \frac{3}{2x}\right) dx} \\
&= \left(x + \frac{27}{7}\right) e^{\frac{\ln(3+x)}{3} - \frac{3\ln(x)}{2}} \\
&= \frac{\left(x + \frac{27}{7}\right)(3+x)^{1/3}}{x^{3/2}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-x^2-15x}{3x^3+9x^2}\, dx} \\
&= z_1 e^{-\frac{2\ln(3+x)}{3} + \frac{5\ln(x)}{6}} \\
&= z_1 \left(\frac{x^{5/6}}{(3+x)^{2/3}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{7x + 27}{7(3+x)^{1/3} x^{2/3}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-x^2-15x}{3x^3+9x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-\frac{4\ln(3+x)}{3} + \frac{5\ln(x)}{3}}}{(y_1)^2}\, dx \\
&= y_1 \left(\frac{21(3+x)^{5/3}(x^2 - 36x - 243)\, e^{-\frac{4\ln(3+x)}{3} + \frac{5\ln(x)}{3}}}{4(7x+27)\, x^{5/3}}\right)
\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{7x+27}{7(3+x)^{1/3} x^{2/3}} \right) \\
&\quad + c_2 \left(\frac{7x+27}{7(3+x)^{1/3} x^{2/3}} \left(\frac{21(3+x)^{5/3} (x^2-36x-243) \mathrm{e}^{-\frac{4\ln(3+x)}{3}+\frac{5\ln(x)}{3}}}{4(7x+27) x^{5/3}} \right) \right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$3x^2(x+3)\left(\frac{d^2}{dx^2}y(x)\right) - x(15+x)\left(\frac{d}{dx}y(x)\right) - 20y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = \frac{20y(x)}{3x^2(x+3)} + \frac{(15+x)\left(\frac{d}{dx}y(x)\right)}{3x(x+3)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x) - \frac{(15+x)\left(\frac{d}{dx}y(x)\right)}{3x(x+3)} - \frac{20y(x)}{3x^2(x+3)} = 0$

☐ Check to see if x_0 is a regular singular point

  - Define functions

    $\left[P_2(x) = -\frac{15+x}{3x(x+3)}, P_3(x) = -\frac{20}{3x^2(x+3)}\right]$

  - $(x+3)\cdot P_2(x)$ is analytic at $x=-3$

    $\left((x+3)\cdot P_2(x)\right)\Big|_{x=-3} = \frac{4}{3}$

  - $(x+3)^2\cdot P_3(x)$ is analytic at $x=-3$

    $\left((x+3)^2\cdot P_3(x)\right)\Big|_{x=-3} = 0$

  - $x=-3$is a regular singular point

    Check to see if x_0 is a regular singular point

    $x_0 = -3$

- Multiply by denominators

  $3x^2(x+3)\left(\frac{d^2}{dx^2}y(x)\right) - x(15+x)\left(\frac{d}{dx}y(x)\right) - 20y(x) = 0$

- Change variables using $x = u-3$ so that the regular singular point is at $u=0$

  $(3u^3-18u^2+27u)\left(\frac{d^2}{du^2}y(u)\right) + (-u^2-9u+36)\left(\frac{d}{du}y(u)\right) - 20y(u) = 0$

- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

☐ Rewrite ODE with series expansions

  - Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..2$

    $u^m\cdot\left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, u^{k+r-1+m}$

  - Shift index using $k->k+1-m$

$$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$$

- Convert $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m = 1..3$

$$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, u^{k+r-2+m}$$

- Shift index using $k- >k+2-m$

$$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\, u^{k+r}$$

Rewrite ODE with series expansions

$$9a_0r(1+3r)\, u^{-1+r} + (9a_1(1+r)(4+3r) - a_0(18r^2-9r+20))\, u^r + \left(\sum_{k=1}^{\infty} (9a_{k+1}(k+1+r)(3k$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$9r(1+3r) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \left\{0, -\frac{1}{3}\right\}$$

- Each term must be 0

$$9a_1(1+r)(4+3r) - a_0(18r^2-9r+20) = 0$$

- Each term in the series must be 0, giving the recursion relation

$$3(-6a_k + a_{k-1} + 9a_{k+1})\, k^2 + (6(-6a_k + a_{k-1} + 9a_{k+1})\, r + 9a_k - 10a_{k-1} + 63a_{k+1})\, k + 3(-6a_k +$$

- Shift index using $k- >k+1$

$$3(-6a_{k+1} + a_k + 9a_{k+2})\,(k+1)^2 + (6(-6a_{k+1} + a_k + 9a_{k+2})\, r + 9a_{k+1} - 10a_k + 63a_{k+2})\,(k+1)$$

- Recursion relation that defines series solution to ODE

$$a_{k+2} = -\frac{3k^2a_k - 18k^2a_{k+1} + 6kra_k - 36kra_{k+1} + 3r^2a_k - 18r^2a_{k+1} - 4ka_k - 27ka_{k+1} - 4ra_k - 27ra_{k+1} - 29a_{k+1}}{9(3k^2+6kr+3r^2+13k+13r+14)}$$

- Recursion relation for $r = 0$

$$a_{k+2} = -\frac{3k^2a_k - 18k^2a_{k+1} - 4ka_k - 27ka_{k+1} - 29a_{k+1}}{9(3k^2+13k+14)}$$

- Solution for $r = 0$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+2} = -\frac{3k^2a_k - 18k^2a_{k+1} - 4ka_k - 27ka_{k+1} - 29a_{k+1}}{9(3k^2+13k+14)}, 36a_1 - 20a_0 = 0\right]$$

- Revert the change of variables $u = x+3$

2.1.177 Problem 179

Internal problem ID [9349]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 179
Date solved : `Monday, January 27, 2025 at 06:01:46 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2(1+x)\,y''+x(1-10x)\,y'-(9-10x)\,y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.239 (sec)

Writing the ode as

$$x^2(1+x)\,y''+\left(-10x^2+x\right)y'+(10x-9)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=x^2(1+x)\\ B&=-10x^2+x\\ C&=10x-9\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned}r&=\frac{s}{t}\\ &=\frac{2AB'-2BA'+B^2-4AC}{4A^2}\end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{80x^2-28x+35}{4\left(x^2+x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned}s&=80x^2-28x+35\\ t&=4\left(x^2+x\right)^2\end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{80x^2-28x+35}{4\left(x^2+x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\,e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.338: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s)\\ &= 4-2\\ &= 2\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^2+x)^2$. There is a pole at $x=0$ of order 2. There is a pole at $x=-1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1,2,4,6,12]$$

Attempting to find a solution using case $n=1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{49}{2x} + \frac{49}{2\,(1+x)} + \frac{35}{4x^2} + \frac{143}{4\,(1+x)^2}$$

For the pole at $x=-1$ let b be the coefficient of $\frac{1}{(1+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{143}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{13}{2}\\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{11}{2}\end{aligned}$$

For the pole at $x=0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{35}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{2}\\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{5}{2}\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{80x^2 - 28x + 35}{4\left(x^2 + x\right)^2}$$

Since the gcd$(s, t) = 1$. This gives $b = 20$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1 + 4b} = 5 \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1 + 4b} = -4
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{80x^2 - 28x + 35}{4\left(x^2 + x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
-1	2	0	$\frac{13}{2}$	$-\frac{11}{2}$
0	2	0	$\frac{7}{2}$	$-\frac{5}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	5	-4

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = 5$ then

$$\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^+ + \alpha_{c_2}^-\right) \\
&= 5 - (4) \\
&= 1
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x - c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x - c_2} \right) + (+)[\sqrt{r}]_\infty \\
&= \frac{13}{2(1 + x)} - \frac{5}{2x} + (0) \\
&= \frac{13}{2(1 + x)} - \frac{5}{2x} \\
&= \frac{8x - 5}{2x(1 + x)}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{13}{2(1+x)} - \frac{5}{2x}\right)(1) + \left(\left(-\frac{13}{2(1+x)^2} + \frac{5}{2x^2}\right) + \left(\frac{13}{2(1+x)} - \frac{5}{2x}\right)^2 - \left(\frac{80x^2-28x+35}{4(x^2+x)^2}\right)\right) = 0$$

$$\frac{-5-8a_0}{x(1+x)} = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\left\{a_0 = -\frac{5}{8}\right\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x - \frac{5}{8}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx} \\
&= \left(x - \frac{5}{8}\right) e^{\int \left(\frac{13}{2(1+x)} - \frac{5}{2x}\right) dx} \\
&= \left(x - \frac{5}{8}\right) e^{-\frac{5\ln(x)}{2} + \frac{13\ln(1+x)}{2}} \\
&= \frac{\left(x - \frac{5}{8}\right)(1+x)^{13/2}}{x^{5/2}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-10x^2+x}{x^2(1+x)}\, dx} \\
&= z_1 e^{-\frac{\ln(x)}{2} + \frac{11\ln(1+x)}{2}} \\
&= z_1 \left(\frac{(1+x)^{11/2}}{\sqrt{x}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{(1+x)^{12}\left(x - \frac{5}{8}\right)}{x^3}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-10x^2+x}{x^2(1+x)}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-\ln(x)+11\ln(1+x)}}{(y_1)^2}\, dx \\
&= y_1 \left(-\frac{8\,e^{-\ln(x)+11\ln(1+x)} x(715x^4 + 572x^3 + 234x^2 + 52x + 5)}{6435(8x-5)(1+x)^{23}}\right)
\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{(1+x)^{12} \left(x - \frac{5}{8}\right)}{x^3} \right) \\
&\quad + c_2 \left(\frac{(1+x)^{12} \left(x - \frac{5}{8}\right)}{x^3} \left(-\frac{8\, \mathrm{e}^{-\ln(x)+11\ln(1+x)} x(715x^4 + 572x^3 + 234x^2 + 52x + 5)}{6435\,(8x-5)\,(1+x)^{23}} \right) \right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve
$x^2(x+1)\left(\frac{d^2}{dx^2}y(x)\right) + x(1-10x)\left(\frac{d}{dx}y(x)\right) - (9-10x)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2
  $\frac{d^2}{dx^2}y(x)$
- Isolate 2nd derivative
  $\frac{d^2}{dx^2}y(x) = -\frac{(-9+10x)y(x)}{(x+1)x^2} + \frac{(-1+10x)\left(\frac{d}{dx}y(x)\right)}{x(x+1)}$
- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin
  $\frac{d^2}{dx^2}y(x) - \frac{(-1+10x)\left(\frac{d}{dx}y(x)\right)}{x(x+1)} + \frac{(-9+10x)y(x)}{(x+1)x^2} = 0$

□ Check to see if x_0 is a regular singular point
  - Define functions
    $\left[P_2(x) = -\frac{-1+10x}{x(x+1)}, P_3(x) = \frac{-9+10x}{(x+1)x^2}\right]$
  - $(x+1)\cdot P_2(x)$ is analytic at $x=-1$
    $\left((x+1)\cdot P_2(x)\right)\Big|_{x=-1} = -11$
  - $(x+1)^2\cdot P_3(x)$ is analytic at $x=-1$
    $\left((x+1)^2\cdot P_3(x)\right)\Big|_{x=-1} = 0$
  - $x=-1$is a regular singular point
    Check to see if x_0 is a regular singular point
    $x_0 = -1$
- Multiply by denominators
  $x^2(x+1)\left(\frac{d^2}{dx^2}y(x)\right) - x(-1+10x)\left(\frac{d}{dx}y(x)\right) + (-9+10x)\,y(x) = 0$
- Change variables using $x = u-1$ so that the regular singular point is at $u=0$
  $(u^3 - 2u^2 + u)\left(\frac{d^2}{du^2}y(u)\right) + (-10u^2 + 21u - 11)\left(\frac{d}{du}y(u)\right) + (-19+10u)\,y(u) = 0$
- Assume series solution for $y(u)$
  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

□ Rewrite ODE with series expansions
  - Convert $u^m \cdot y(u)$ to series expansion for $m = 0..1$
    $u^m \cdot y(u) = \sum_{k=0}^{\infty} a_k u^{k+r+m}$
  - Shift index using $k->k-m$
    $u^m \cdot y(u) = \sum_{k=m}^{\infty} a_{k-m} u^{k+r}$

- Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..2$

  $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, u^{k+r-1+m}$
- Shift index using $k- >k+1-m$

  $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$
- Convert $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m = 1..3$

  $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, u^{k+r-2+m}$
- Shift index using $k- >k+2-m$

  $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\, u^{k+r}$

  Rewrite ODE with series expansions

  $a_0r(-12+r)\, u^{-1+r} + (a_1(1+r)(-11+r) - a_0(2r^2-23r+19))\, u^r + \left(\sum_{k=1}^{\infty} (a_{k+1}(k+1+r)(k-1\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r(-12+r) = 0$
- Values of r that satisfy the indicial equation

  $r \in \{0, 12\}$
- Each term must be 0

  $a_1(1+r)(-11+r) - a_0(2r^2-23r+19) = 0$
- Each term in the series must be 0, giving the recursion relation

  $(-2a_k + a_{k-1} + a_{k+1})\, k^2 + ((-4a_k + 2a_{k-1} + 2a_{k+1})\, r + 23a_k - 13a_{k-1} - 10a_{k+1})\, k + (-2a_k + a_{k-1}$
- Shift index using $k- >k+1$

  $(-2a_{k+1} + a_k + a_{k+2})(k+1)^2 + ((-4a_{k+1} + 2a_k + 2a_{k+2})\, r + 23a_{k+1} - 13a_k - 10a_{k+2})(k+1) + ($
- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{k^2a_k - 2k^2a_{k+1} + 2kra_k - 4kra_{k+1} + r^2a_k - 2r^2a_{k+1} - 11ka_k + 19ka_{k+1} - 11ra_k + 19ra_{k+1} + 10a_k + 2a_{k+1}}{k^2+2kr+r^2-8k-8r-20}$
- Recursion relation for $r = 0$

  $a_{k+2} = -\frac{k^2a_k - 2k^2a_{k+1} - 11ka_k + 19ka_{k+1} + 10a_k + 2a_{k+1}}{k^2-8k-20}$
- Series not valid for $r = 0$, division by 0 in the recursion relation at $k = 10$

  $a_{k+2} = -\frac{k^2a_k - 2k^2a_{k+1} - 11ka_k + 19ka_{k+1} + 10a_k + 2a_{k+1}}{k^2-8k-20}$
- Recursion relation for $r = 12$

  $a_{k+2} = -\frac{k^2a_k - 2k^2a_{k+1} + 13ka_k - 29ka_{k+1} + 22a_k - 58a_{k+1}}{k^2+16k+28}$
- Solution for $r = 12$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+12}, a_{k+2} = -\frac{k^2a_k - 2k^2a_{k+1} + 13ka_k - 29ka_{k+1} + 22a_k - 58a_{k+1}}{k^2+16k+28}, 13a_1 - 31a_0 = 0\right]$
- Revert the change of variables $u = x+1$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k(x+1)^{k+12}, a_{k+2} = -\frac{k^2a_k - 2k^2a_{k+1} + 13ka_k - 29ka_{k+1} + 22a_k - 58a_{k+1}}{k^2+16k+28}, 13a_1 - 31a_0 = 0\right]$

Solve

$$x^2(1+x)\,y''+3x^2y'-(6-x)\,y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.211 (sec)

Writing the ode as

$$x^2(1+x)\,y''+3x^2y'+(x-6)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=x^2(1+x)\\B&=3x^2\\C&=x-6\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned}r&=\frac{s}{t}\\&=\frac{2AB'-2BA'+B^2-4AC}{4A^2}\end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{-x^2+20x+24}{4\left(x^2+x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned}s&=-x^2+20x+24\\t&=4\left(x^2+x\right)^2\end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{-x^2+20x+24}{4\left(x^2+x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.340: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^2 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{7}{x} + \frac{6}{x^2} + \frac{3}{4\,(1 + x)^2} + \frac{7}{1 + x}$$

For the pole at $x = -1$ let b be the coefficient of $\frac{1}{(1+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{1}{2} \end{aligned}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = 6$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = 3 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -2 \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{-x^2+20x+24}{4\left(x^2+x\right)^2}$$

Since the $\gcd(s,t)=1$. This gives $b=-\frac{1}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= 0\\ \alpha_\infty^+ &= \frac{1}{2}+\sqrt{1+4b} = \frac{1}{2}\\ \alpha_\infty^- &= \frac{1}{2}-\sqrt{1+4b} = \frac{1}{2}\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{-x^2+20x+24}{4\left(x^2+x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
-1	2	0	$\frac{3}{2}$	$-\frac{1}{2}$
0	2	0	3	-2

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma}\alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$\begin{aligned}d &= \alpha_\infty^- - \left(\alpha_{c_1}^+ + \alpha_{c_2}^-\right)\\ &= \frac{1}{2} - \left(-\frac{1}{2}\right)\\ &= 1\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2}\right) + (-)[\sqrt{r}]_\infty\\ &= \frac{3}{2\,(1+x)} - \frac{2}{x} + (-)\,(0)\\ &= \frac{3}{2\,(1+x)} - \frac{2}{x}\\ &= -\frac{x+4}{2x\,(1+x)}\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p''+2\omega p'+\left(\omega'+\omega^2-r\right)p=0 \tag{1A}$$

Let

$$p(x)=x+a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(\frac{3}{2\left(1+x\right)}-\frac{2}{x}\right)(1)+\left(\left(-\frac{3}{2\left(1+x\right)^2}+\frac{2}{x^2}\right)+\left(\frac{3}{2\left(1+x\right)}-\frac{2}{x}\right)^2-\left(\frac{-x^2+20x+24}{4\left(x^2+x\right)^2}\right)\right)=0$$

$$\frac{-4+a_0}{x\left(1+x\right)}=0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0=4\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x)=x+4$$

Therefore the first solution to the ode $z''=rz$ is

$$\begin{aligned}
z_1(x)&=pe^{\int \omega\,dx}\\
&=(x+4)\,\mathrm{e}^{\int \left(\frac{3}{2(1+x)}-\frac{2}{x}\right)dx}\\
&=(x+4)\,\mathrm{e}^{\frac{3\ln(1+x)}{2}-2\ln(x)}\\
&=\frac{(x+4)\left(1+x\right)^{3/2}}{x^2}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1&=z_1e^{\int -\frac{1}{2}\frac{B}{A}\,dx}\\
&=z_1e^{-\int \frac{1}{2}\frac{3x^2}{x^2(1+x)}\,dx}\\
&=z_1e^{-\frac{3\ln(1+x)}{2}}\\
&=z_1\left(\frac{1}{\left(1+x\right)^{3/2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1=\frac{x+4}{x^2}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2=y_1\int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2&=y_1\int \frac{e^{\int -\frac{3x^2}{x^2(1+x)}\,dx}}{\left(y_1\right)^2}\,dx\\
&=y_1\int \frac{e^{-3\ln(1+x)}}{\left(y_1\right)^2}\,dx\\
&=y_1\left(\ln\left(1+x\right)-\frac{1}{18\left(1+x\right)^2}+\frac{14}{27\left(1+x\right)}+\frac{256}{27\left(x+4\right)}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{x+4}{x^2}\right) + c_2 \left(\frac{x+4}{x^2}\left(\ln(1+x) - \frac{1}{18(1+x)^2} + \frac{14}{27(1+x)} + \frac{256}{27(x+4)}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2(x+1)\left(\frac{d^2}{dx^2}y(x)\right) + 3x^2\left(\frac{d}{dx}y(x)\right) - (-x+6)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{(-6+x)y(x)}{(x+1)x^2} - \frac{3\left(\frac{d}{dx}y(x)\right)}{x+1}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x) + \frac{3\left(\frac{d}{dx}y(x)\right)}{x+1} + \frac{(-6+x)y(x)}{(x+1)x^2} = 0$

□ Check to see if x_0 is a regular singular point

  - Define functions

    $\left[P_2(x) = \frac{3}{x+1}, P_3(x) = \frac{-6+x}{(x+1)x^2}\right]$

  - $(x+1)\cdot P_2(x)$ is analytic at $x=-1$

    $\left((x+1)\cdot P_2(x)\right)\Big|_{x=-1} = 3$

  - $(x+1)^2\cdot P_3(x)$ is analytic at $x=-1$

    $\left((x+1)^2\cdot P_3(x)\right)\Big|_{x=-1} = 0$

  - $x=-1$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = -1$

- Multiply by denominators

  $x^2(x+1)\left(\frac{d^2}{dx^2}y(x)\right) + 3x^2\left(\frac{d}{dx}y(x)\right) + (-6+x)\,y(x) = 0$

- Change variables using $x = u-1$ so that the regular singular point is at $u=0$

  $(u^3-2u^2+u)\left(\frac{d^2}{du^2}y(u)\right) + (3u^2-6u+3)\left(\frac{d}{du}y(u)\right) + (-7+u)\,y(u) = 0$

- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

□ Rewrite ODE with series expansions

  - Convert $u^m \cdot y(u)$ to series expansion for $m = 0..1$

    $u^m \cdot y(u) = \sum_{k=0}^{\infty} a_k u^{k+r+m}$

  - Shift index using $k->k-m$

    $u^m \cdot y(u) = \sum_{k=m}^{\infty} a_{k-m} u^{k+r}$

  - Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..2$

$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, u^{k+r-1+m}$

- Shift index using $k->k+1-m$

  $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$

- Convert $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m = 1..3$

  $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, u^{k+r-2+m}$

- Shift index using $k->k+2-m$

  $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, u^{k+r}$

  Rewrite ODE with series expansions

  $a_0 r(2+r)\, u^{-1+r} + (a_1(1+r)\,(3+r) - a_0(2r^2+4r+7))\, u^r + \left(\sum_{k=1}^{\infty} (a_{k+1}(k+r+1)\,(k+3+r)\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r(2+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{-2, 0\}$

- Each term must be 0

  $a_1(1+r)\,(3+r) - a_0(2r^2+4r+7) = 0$

- Each term in the series must be 0, giving the recursion relation

  $a_{k-1}(k+r)^2 + a_{k+1}(k+r+1)\,(k+3+r) - 2\left(k^2 + (2r+2)\,k + r^2 + 2r + \frac{7}{2}\right) a_k = 0$

- Shift index using $k->k+1$

  $a_k(k+r+1)^2 + a_{k+2}(k+r+2)\,(k+4+r) - 2\left((k+1)^2 + (2r+2)\,(k+1) + r^2 + 2r + \frac{7}{2}\right) a_{k+1}$

- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{k^2a_k - 2k^2a_{k+1} + 2kra_k - 4kra_{k+1} + r^2a_k - 2r^2a_{k+1} + 2ka_k - 8ka_{k+1} + 2ra_k - 8ra_{k+1} + a_k - 13a_{k+1}}{(k+r+2)(k+4+r)}$

- Recursion relation for $r = -2$

  $a_{k+2} = -\frac{k^2a_k - 2k^2a_{k+1} - 2ka_k + a_k - 5a_{k+1}}{k(k+2)}$

- Series not valid for $r = -2$, division by 0 in the recursion relation at $k = 0$

  $a_{k+2} = -\frac{k^2a_k - 2k^2a_{k+1} - 2ka_k + a_k - 5a_{k+1}}{k(k+2)}$

- Recursion relation for $r = 0$

  $a_{k+2} = -\frac{k^2a_k - 2k^2a_{k+1} + 2ka_k - 8ka_{k+1} + a_k - 13a_{k+1}}{(k+2)(k+4)}$

- Solution for $r = 0$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+2} = -\frac{k^2a_k - 2k^2a_{k+1} + 2ka_k - 8ka_{k+1} + a_k - 13a_{k+1}}{(k+2)(k+4)}, 3a_1 - 7a_0 = 0\right]$

- Revert the change of variables $u = x+1$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k(x+1)^k, a_{k+2} = -\frac{k^2a_k - 2k^2a_{k+1} + 2ka_k - 8ka_{k+1} + a_k - 13a_{k+1}}{(k+2)(k+4)}, 3a_1 - 7a_0 = 0\right]$

CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2(1+2x)\,y''-2x(3+14x)\,y'+(6+100x)\,y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.200 (sec)

Writing the ode as

$$\left(2x^3+x^2\right)y''+\left(-28x^2-6x\right)y'+(6+100x)\,y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A&=2x^3+x^2\\ B&=-28x^2-6x \\ C&=6+100x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r&=\frac{s}{t} \\ &=\frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{24x^2-16x+6}{\left(2x^2+x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s&=24x^2-16x+6\\ t&=\left(2x^2+x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{24x^2-16x+6}{\left(2x^2+x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.342: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (2x^2 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -\frac{1}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{20}{\left(x + \frac{1}{2}\right)^2} + \frac{40}{x + \frac{1}{2}} - \frac{40}{x} + \frac{6}{x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = 6$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 3 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -2 \end{aligned}$$

For the pole at $x = -\frac{1}{2}$ let b be the coefficient of $\frac{1}{\left(x+\frac{1}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 20$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 5 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -4 \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{24x^2 - 16x + 6}{(2x^2 + x)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = 6$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = 3 \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -2
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{24x^2 - 16x + 6}{(2x^2 + x)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	3	-2
$-\frac{1}{2}$	2	0	5	-4

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	3	-2

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = 3$ then

$$\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^- + \alpha_{c_2}^+\right) \\
&= 3 - (3) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x-c_2} \right) + (+)[\sqrt{r}]_\infty \\
&= -\frac{2}{x} + \frac{5}{x+\frac{1}{2}} + (0) \\
&= -\frac{2}{x} + \frac{5}{x+\frac{1}{2}} \\
&= \frac{-2+6x}{2x^2+x}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{2}{x} + \frac{5}{x+\frac{1}{2}}\right)(0) + \left(\left(\frac{2}{x^2} - \frac{5}{\left(x+\frac{1}{2}\right)^2}\right) + \left(-\frac{2}{x} + \frac{5}{x+\frac{1}{2}}\right)^2 - \left(\frac{24x^2 - 16x + 6}{\left(2x^2+x\right)^2}\right)\right) = 0$$
$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= pe^{\int \omega\, dx} \\ &= \mathrm{e}^{\int \left(-\frac{2}{x} + \frac{5}{x+\frac{1}{2}}\right) dx} \\ &= \frac{(1+2x)^5}{x^2} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-28x^2-6x}{2x^3+x^2}\, dx} \\ &= z_1 e^{4\ln(1+2x)+3\ln(x)} \\ &= z_1\left((1+2x)^4 x^3\right) \end{aligned}$$

Which simplifies to

$$y_1 = (1+2x)^9 x$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-28x^2-6x}{2x^3+x^2}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{8\ln(1+2x)+6\ln(x)}}{(y_1)^2}\, dx \\ &= y_1\left(-\frac{\left(2016x^4 + 672x^3 + 144x^2 + 18x + 1\right)\mathrm{e}^{8\ln(1+2x)+6\ln(x)}}{20160\,(1+2x)^{17} x^6}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left((1+2x)^9 x\right) + c_2\left((1+2x)^9 x\left(-\frac{\left(2016x^4 + 672x^3 + 144x^2 + 18x + 1\right)\mathrm{e}^{8\ln(1+2x)+6\ln(x)}}{20160\,(1+2x)^{17} x^6}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

2.1.180 Problem 182

Internal problem ID [9352]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 182
Date solved : `Monday, January 27, 2025 at 06:01:48 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2(1+x)\,y''-x(6+11x)\,y'+(6+32x)\,y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.218 (sec)

Writing the ode as

$$x^2(1+x)\,y''+\left(-11x^2-6x\right)y'+(6+32x)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2(1+x)\\ B &= -11x^2-6x \\ C &= 6+32x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{15x^2+4x+24}{4\left(x^2+x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 15x^2+4x+24 \\ t &= 4\left(x^2+x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{15x^2+4x+24}{4\left(x^2+x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.344: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^2 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{35}{4\,(1+x)^2} + \frac{11}{1+x} - \frac{11}{x} + \frac{6}{x^2}$$

For the pole at $x = -1$ let b be the coefficient of $\frac{1}{(1+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{35}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{5}{2} \end{aligned}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = 6$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 3 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -2 \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{15x^2 + 4x + 24}{4\left(x^2 + x\right)^2}$$

Since the $\gcd(s, t) = 1$. This gives $b = \frac{15}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{5}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{3}{2}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{15x^2 + 4x + 24}{4\left(x^2 + x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
-1	2	0	$\frac{7}{2}$	$-\frac{5}{2}$
0	2	0	3	-2

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{5}{2}$	$-\frac{3}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{5}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^+ + \alpha_{c_2}^-\right) \\
&= \frac{5}{2} - \left(\frac{3}{2}\right) \\
&= 1
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x - c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x - c_2} \right) + (+)[\sqrt{r}]_\infty \\
&= \frac{7}{2\left(1 + x\right)} - \frac{2}{x} + (0) \\
&= \frac{7}{2\left(1 + x\right)} - \frac{2}{x} \\
&= \frac{3x - 4}{2x\left(1 + x\right)}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{7}{2(1+x)} - \frac{2}{x}\right)(1) + \left(\left(-\frac{7}{2(1+x)^2} + \frac{2}{x^2}\right) + \left(\frac{7}{2(1+x)} - \frac{2}{x}\right)^2 - \left(\frac{15x^2 + 4x + 24}{4(x^2+x)^2}\right)\right) = 0$$

$$\frac{-4 - 3a_0}{x(1+x)} = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\left\{a_0 = -\frac{4}{3}\right\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x - \frac{4}{3}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx} \\
&= \left(x - \frac{4}{3}\right) e^{\int \left(\frac{7}{2(1+x)} - \frac{2}{x}\right) dx} \\
&= \left(x - \frac{4}{3}\right) e^{-2\ln(x) + \frac{7\ln(1+x)}{2}} \\
&= \frac{\left(x - \frac{4}{3}\right)(1+x)^{7/2}}{x^2}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-11x^2 - 6x}{x^2(1+x)}\, dx} \\
&= z_1 e^{3\ln(x) + \frac{5\ln(1+x)}{2}} \\
&= z_1 \left(x^3 (1+x)^{5/2}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = x(1+x)^6 \left(x - \frac{4}{3}\right)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-11x^2 - 6x}{x^2(1+x)}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{6\ln(x) + 5\ln(1+x)}}{(y_1)^2}\, dx \\
&= y_1 \left(-\frac{3\, e^{6\ln(x) + 5\ln(1+x)}(35x^3 + 42x^2 + 21x + 4)}{140(3x-4)\, x^6 (1+x)^{11}}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1y_1 + c_2y_2 \\
&= c_1\left(x(1+x)^6\left(x-\frac{4}{3}\right)\right) \\
&\quad + c_2\left(x(1+x)^6\left(x-\frac{4}{3}\right)\left(-\frac{3\,\mathrm{e}^{6\ln(x)+5\ln(1+x)}(35x^3+42x^2+21x+4)}{140\,(3x-4)\,x^6\,(1+x)^{11}}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2(x+1)\left(\frac{d^2}{dx^2}y(x)\right)-x(6+11x)\left(\frac{d}{dx}y(x)\right)+(6+32x)\,y(x)=0$

2.1.181 Problem 183

Internal problem ID [9353]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 183
Date solved : Monday, January 27, 2025 at 06:01:48 PM
CAS classification : [[_2nd_order, _with_linear_symmetries]]

Solve

$$4x^2(1+x)\,y''+4x(1+4x)\,y'-(49+27x)\,y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.212 (sec)

Writing the ode as

$$\left(4x^3+4x^2\right)y''+\left(16x^2+4x\right)y'+(-27x-49)\,y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=4x^3+4x^2\\B&=16x^2+4x\\C&=-27x-49\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned}r&=\frac{s}{t}\\&=\frac{2AB'-2BA'+B^2-4AC}{4A^2}\end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{35x^2+80x+48}{4\left(x^2+x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned}s&=35x^2+80x+48\\t&=4\left(x^2+x\right)^2\end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{35x^2+80x+48}{4\left(x^2+x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.346: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^2+x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{12}{x^2} - \frac{4}{x} + \frac{4}{1+x} + \frac{3}{4\,(1+x)^2}$$

For the pole at $x = -1$ let b be the coefficient of $\frac{1}{(1+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = 12$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 4 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -3 \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{35x^2 + 80x + 48}{4\left(x^2 + x\right)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{35}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{5}{2}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{35x^2 + 80x + 48}{4\left(x^2 + x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
-1	2	0	$\frac{3}{2}$	$-\frac{1}{2}$
0	2	0	4	-3

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{7}{2}$	$-\frac{5}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{7}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^- + \alpha_{c_2}^+\right) \\
&= \frac{7}{2} - \left(\frac{7}{2}\right) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x-c_2} \right) + (+)[\sqrt{r}]_\infty \\
&= -\frac{1}{2(1+x)} + \frac{4}{x} + (0) \\
&= -\frac{1}{2(1+x)} + \frac{4}{x} \\
&= \frac{7x+8}{2x(1+x)}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{2(1+x)} + \frac{4}{x}\right)(0) + \left(\left(\frac{1}{2(1+x)^2} - \frac{4}{x^2}\right) + \left(-\frac{1}{2(1+x)} + \frac{4}{x}\right)^2 - \left(\frac{35x^2 + 80x + 48}{4(x^2+x)^2}\right)\right) = 0$$
$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega\, dx} \\ &= \mathrm{e}^{\int \left(-\frac{1}{2(1+x)} + \frac{4}{x}\right) dx} \\ &= \frac{x^4}{\sqrt{1+x}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{16x^2+4x}{4x^3+4x^2}\, dx} \\ &= z_1 e^{-\frac{\ln(x)}{2} - \frac{3\ln(1+x)}{2}} \\ &= z_1 \left(\frac{1}{\sqrt{x}\,(1+x)^{3/2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{x^{7/2}}{(1+x)^2}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{16x^2+4x}{4x^3+4x^2}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-\ln(x) - 3\ln(1+x)}}{(y_1)^2}\, dx \\ &= y_1 \left(-\frac{(7x+6)(1+x)^3\, \mathrm{e}^{-\ln(x) - 3\ln(1+x)}}{42x^6}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\frac{x^{7/2}}{(1+x)^2}\right) + c_2 \left(\frac{x^{7/2}}{(1+x)^2}\left(-\frac{(7x+6)(1+x)^3\, \mathrm{e}^{-\ln(x) - 3\ln(1+x)}}{42x^6}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$4x^2(x+1)\left(\frac{d^2}{dx^2}y(x)\right)+4x(4x+1)\left(\frac{d}{dx}y(x)\right)-(49+27x)\,y(x)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x)=\frac{(49+27x)y(x)}{4x^2(x+1)}-\frac{(4x+1)\left(\frac{d}{dx}y(x)\right)}{x(x+1)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x)+\frac{(4x+1)\left(\frac{d}{dx}y(x)\right)}{x(x+1)}-\frac{(49+27x)y(x)}{4x^2(x+1)}=0$

☐ Check to see if x_0 is a regular singular point

- ○ Define functions

  $\left[P_2(x)=\frac{4x+1}{x(x+1)},P_3(x)=-\frac{49+27x}{4x^2(x+1)}\right]$

- ○ $(x+1)\cdot P_2(x)$ is analytic at $x=-1$

  $\left((x+1)\cdot P_2(x)\right)\Big|_{x=-1}=3$

- ○ $(x+1)^2\cdot P_3(x)$ is analytic at $x=-1$

  $\left((x+1)^2\cdot P_3(x)\right)\Big|_{x=-1}=0$

- ○ $x=-1$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=-1$

- Multiply by denominators

  $4x^2(x+1)\left(\frac{d^2}{dx^2}y(x)\right)+4x(4x+1)\left(\frac{d}{dx}y(x)\right)+(-27x-49)\,y(x)=0$

- Change variables using $x=u-1$ so that the regular singular point is at $u=0$

  $(4u^3-8u^2+4u)\left(\frac{d^2}{du^2}y(u)\right)+(16u^2-28u+12)\left(\frac{d}{du}y(u)\right)+(-27u-22)\,y(u)=0$

- Assume series solution for $y(u)$

  $y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

☐ Rewrite ODE with series expansions

- ○ Convert $u^m\cdot y(u)$ to series expansion for $m=0..1$

  $u^m\cdot y(u)=\sum_{k=0}^{\infty}a_k u^{k+r+m}$

- ○ Shift index using $k->k-m$

  $u^m\cdot y(u)=\sum_{k=m}^{\infty}a_{k-m}u^{k+r}$

- ○ Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..2$

  $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,u^{k+r-1+m}$

- ○ Shift index using $k->k+1-m$

  $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,u^{k+r}$

- ○ Convert $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m=1..3$

  $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)(k+r-1)\,u^{k+r-2+m}$

- ○ Shift index using $k->k+2-m$

$$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,u^{k+r}$$

Rewrite ODE with series expansions

$$4a_0r(2+r)\,u^{-1+r} + (4a_1(1+r)\,(3+r) - 2a_0(4r^2+10r+11))\,u^r + \left(\sum_{k=1}^{\infty} (4a_{k+1}(k+1+r)\,(k+3\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $4r(2+r) = 0$
- Values of r that satisfy the indicial equation
  $r \in \{-2, 0\}$
- Each term must be 0
  $4a_1(1+r)\,(3+r) - 2a_0(4r^2+10r+11) = 0$
- Each term in the series must be 0, giving the recursion relation
  $4(-2a_k + a_{k-1} + a_{k+1})\,k^2 + 4(2(-2a_k + a_{k-1} + a_{k+1})\,r - 5a_k + a_{k-1} + 4a_{k+1})\,k + 4(-2a_k + a_{k-1} +$
- Shift index using $k- >k+1$
  $4(-2a_{k+1} + a_k + a_{k+2})\,(k+1)^2 + 4(2(-2a_{k+1} + a_k + a_{k+2})\,r - 5a_{k+1} + a_k + 4a_{k+2})\,(k+1) + 4(-2$
- Recursion relation that defines series solution to ODE
  $a_{k+2} = -\frac{4k^2a_k-8k^2a_{k+1}+8kra_k-16kra_{k+1}+4r^2a_k-8r^2a_{k+1}+12ka_k-36ka_{k+1}+12ra_k-36ra_{k+1}-27a_k-50a_{k+1}}{4(k^2+2kr+r^2+6k+6r+8)}$
- Recursion relation for $r = -2$
  $a_{k+2} = -\frac{4k^2a_k-8k^2a_{k+1}-4ka_k-4ka_{k+1}-35a_k-10a_{k+1}}{4(k^2+2k)}$
- Series not valid for $r = -2$, division by 0 in the recursion relation at $k = 0$
  $a_{k+2} = -\frac{4k^2a_k-8k^2a_{k+1}-4ka_k-4ka_{k+1}-35a_k-10a_{k+1}}{4(k^2+2k)}$
- Recursion relation for $r = 0$
  $a_{k+2} = -\frac{4k^2a_k-8k^2a_{k+1}+12ka_k-36ka_{k+1}-27a_k-50a_{k+1}}{4(k^2+6k+8)}$
- Solution for $r = 0$
  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+2} = -\frac{4k^2a_k-8k^2a_{k+1}+12ka_k-36ka_{k+1}-27a_k-50a_{k+1}}{4(k^2+6k+8)}, 12a_1 - 22a_0 = 0\right]$
- Revert the change of variables $u = x+1$

Solve

$$x^2\left(x^2+1\right)y''-x\left(-2x^2+7\right)y'+12y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.301 (sec)

Writing the ode as

$$\left(x^4+x^2\right)y''+\left(2x^3-7x\right)y'+12y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^4+x^2 \\ B &= 2x^3-7x \\ C &= 12 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{-30x^2+15}{4\left(x^3+x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -30x^2+15 \\ t &= 4\left(x^3+x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{-30x^2+15}{4\left(x^3+x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.348: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 2 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^3 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = i$ of order 2. There is a pole at $x = -i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{45}{16\,(x-i)^2} + \frac{45}{16\,(x+i)^2} + \frac{75i}{16\,(x-i)} - \frac{75i}{16\,(x+i)} + \frac{15}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{15}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{2} \end{aligned}$$

For the pole at $x = i$ let b be the coefficient of $\frac{1}{(x-i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{45}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{9}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{5}{4} \end{aligned}$$

For the pole at $x = -i$ let b be the coefficient of $\frac{1}{(x+i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{45}{16}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{9}{4} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{5}{4}
\end{aligned}
$$

Since the order of r at ∞ is $4 > 2$ then

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= 0 \\
\alpha_\infty^- &= 1
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{-30x^2 + 15}{4\left(x^3 + x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{5}{2}$	$-\frac{3}{2}$
i	2	0	$\frac{9}{4}$	$-\frac{5}{4}$
$-i$	2	0	$\frac{9}{4}$	$-\frac{5}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = 0$ then

$$
\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^+ + \alpha_{c_2}^- + \alpha_{c_3}^-\right) \\
&= 0 - (0) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

Substituting the above values in the above results in

$$
\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2} \right) + \left((-)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^-}{x-c_3} \right) + (+)[\sqrt{r}]_\infty \\
&= \frac{5}{2x} - \frac{5}{4\left(x-i\right)} - \frac{5}{4\left(x+i\right)} + (0) \\
&= \frac{5}{2x} - \frac{5}{4\left(x-i\right)} - \frac{5}{4\left(x+i\right)} \\
&= \frac{5}{2x\left(x^2+1\right)}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{5}{2x} - \frac{5}{4(x-i)} - \frac{5}{4(x+i)}\right)(0) + \left(\left(-\frac{5}{2x^2} + \frac{5}{4(x-i)^2} + \frac{5}{4(x+i)^2}\right) + \left(\frac{5}{2x} - \frac{5}{4(x-i)} - \frac{}{4(}\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega\, dx} \\ &= \mathrm{e}^{\int \left(\frac{5}{2x} - \frac{5}{4(x-i)} - \frac{5}{4(x+i)}\right) dx} \\ &= \frac{x^{5/2}}{(x^2+1)^{5/4}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{2x^3-7x}{x^4+x^2}\, dx} \\ &= z_1 e^{\frac{7\ln(x)}{2} - \frac{9\ln(x^2+1)}{4}} \\ &= z_1 \left(\frac{x^{7/2}}{(x^2+1)^{9/4}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{x^6}{(x^2+1)^{7/2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{2x^3-7x}{x^4+x^2}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{7\ln(x) - \frac{9\ln(x^2+1)}{2}}}{(y_1)^2}\, dx \\ &= y_1 \left(-\frac{(x^2+1)^{7/2}}{4x^4} - \frac{3(x^2+1)^{7/2}}{8x^2} + \frac{3(x^2+1)^{5/2}}{8} + \frac{5(x^2+1)^{3/2}}{8} + \frac{15\sqrt{x^2+1}}{8} \right. \\ &\qquad \left. - \frac{15 \operatorname{arctanh}\left(\frac{1}{\sqrt{x^2+1}}\right)}{8}\right) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{x^6}{(x^2+1)^{7/2}}\right) \\
&\quad + c_2\left(\frac{x^6}{(x^2+1)^{7/2}}\left(-\frac{(x^2+1)^{7/2}}{4x^4} - \frac{3(x^2+1)^{7/2}}{8x^2} + \frac{3(x^2+1)^{5/2}}{8} + \frac{5(x^2+1)^{3/2}}{8} + \frac{15\sqrt{x^2+1}}{8} - \frac{15\operatorname{arctanh}\left(\right.}{8}\right.\right.
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2(x^2+1)\left(\frac{d^2}{dx^2}y(x)\right) - x(-2x^2+7)\left(\frac{d}{dx}y(x)\right) + 12y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{12y(x)}{x^2(x^2+1)} - \frac{(2x^2-7)\left(\frac{d}{dx}y(x)\right)}{x(x^2+1)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x) + \frac{(2x^2-7)\left(\frac{d}{dx}y(x)\right)}{x(x^2+1)} + \frac{12y(x)}{x^2(x^2+1)} = 0$

☐ Check to see if x_0 is a regular singular point

  - Define functions

    $\left[P_2(x) = \frac{2x^2-7}{x(x^2+1)}, P_3(x) = \frac{12}{x^2(x^2+1)}\right]$

  - $x \cdot P_2(x)$ is analytic at $x = 0$

    $(x \cdot P_2(x))\bigg|_{x=0} = -7$

  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $(x^2 \cdot P_3(x))\bigg|_{x=0} = 12$

  - $x = 0$is a regular singular point

    Check to see if x_0 is a regular singular point

    $x_0 = 0$

- Multiply by denominators

  $x^2(x^2+1)\left(\frac{d^2}{dx^2}y(x)\right) + x(2x^2-7)\left(\frac{d}{dx}y(x)\right) + 12y(x) = 0$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

  - Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m = 1..3$

    $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1+m}$

  - Shift index using $k- >k+1-m$

    $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$

  - Convert $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m = 2..4$

$$x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, x^{k+r-2+m}$$

- Shift index using $k->k+2-m$

$$x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0(-2+r)(-6+r)\, x^r + a_1(-1+r)(-5+r)\, x^{1+r} + \left(\sum_{k=2}^{\infty} (a_k(k+r-2)(k+r-6) + a_{k-2}(k+$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $(-2+r)(-6+r) = 0$
- Values of r that satisfy the indicial equation
  $r \in \{2, 6\}$
- Each term must be 0
  $a_1(-1+r)(-5+r) = 0$
- Solve for the dependent coefficient(s)
  $a_1 = 0$
- Each term in the series must be 0, giving the recursion relation
  $(k+r-2)(a_k(k+r-6) + a_{k-2}(k+r-1)) = 0$
- Shift index using $k->k+2$
  $(k+r)(a_{k+2}(k-4+r) + a_k(k+r+1)) = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+2} = -\frac{a_k(k+r+1)}{k-4+r}$
- Recursion relation for $r = 2$
  $a_{k+2} = -\frac{a_k(k+3)}{k-2}$
- Series not valid for $r = 2$, division by 0 in the recursion relation at $k = 2$
  $a_{k+2} = -\frac{a_k(k+3)}{k-2}$
- Recursion relation for $r = 6$
  $a_{k+2} = -\frac{a_k(k+7)}{k+2}$
- Solution for $r = 6$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+6}, a_{k+2} = -\frac{a_k(k+7)}{k+2}, a_1 = 0\right]$

2.1.183 Problem 185

Internal problem ID [9355]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 185
Date solved : `Monday, January 27, 2025 at 06:01:50 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' - x\left(-x^2+7\right)y' + 12y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.266 (sec)

Writing the ode as

$$x^2y'' + \left(x^3-7x\right)y' + 12y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= x^3-7x \\ C &= 12 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^4-12x^2+15}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^4-12x^2+15 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^4-12x^2+15}{4x^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.350: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 4 \\ &= -2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{x^2}{4} - 3 + \frac{15}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{15}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x}{2} - \frac{3}{x} - \frac{21}{4x^3} - \frac{63}{2x^5} - \frac{3465}{16x^7} - \frac{13041}{8x^9} - \frac{417501}{32x^{11}} - \frac{1744659}{16x^{13}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= \frac{x}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{x^2}{4}$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^4 - 12x^2 + 15}{4x^2} \\ &= Q + \frac{R}{4x^2} \\ &= \left(\frac{x^2}{4} - 3\right) + \left(\frac{15}{4x^2}\right) \\ &= \frac{x^2}{4} - 3 + \frac{15}{4x^2} \end{aligned}$$

We see that the coefficient of the term x in the quotient is -3. Now b can be found.

$$\begin{aligned} b &= (-3) - (0) \\ &= -3 \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{x}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-3}{\frac{1}{2}} - 1\right) &= -\frac{7}{2} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-3}{\frac{1}{2}} - 1\right) &= \frac{5}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^4 - 12x^2 + 15}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{5}{2}$	$-\frac{3}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-2	$\frac{x}{2}$	$-\frac{7}{2}$	$\frac{5}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{5}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^+\right) \\ &= \frac{5}{2} - \left(\frac{5}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{5}{2x} + (-)\left(\frac{x}{2}\right) \\ &= \frac{5}{2x} - \frac{x}{2} \\ &= \frac{5}{2x} - \frac{x}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(\frac{5}{2x} - \frac{x}{2}\right)(0) + \left(\left(-\frac{5}{2x^2} - \frac{1}{2}\right) + \left(\frac{5}{2x} - \frac{x}{2}\right)^2 - \left(\frac{x^4 - 12x^2 + 15}{4x^2}\right)\right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= e^{\int \left(\frac{5}{2x} - \frac{x}{2}\right) dx} \\ &= x^{5/2} e^{-\frac{x^2}{4}} \end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{x^3-7x}{x^2}\,dx} \\
&= z_1 e^{-\frac{x^2}{4}+\frac{7\ln(x)}{2}} \\
&= z_1 \left(x^{7/2}\mathrm{e}^{-\frac{x^2}{4}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = x^6\mathrm{e}^{-\frac{x^2}{2}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x^3-7x}{x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{x^2}{2}+7\ln(x)}}{(y_1)^2}\,dx \\
&= y_1 \left(-\frac{\mathrm{e}^{\frac{x^2}{2}}}{4x^4}-\frac{\mathrm{e}^{\frac{x^2}{2}}}{8x^2}-\frac{\mathrm{Ei}_1\left(-\frac{x^2}{2}\right)}{16}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(x^6\mathrm{e}^{-\frac{x^2}{2}}\right) + c_2\left(x^6\mathrm{e}^{-\frac{x^2}{2}}\left(-\frac{\mathrm{e}^{\frac{x^2}{2}}}{4x^4}-\frac{\mathrm{e}^{\frac{x^2}{2}}}{8x^2}-\frac{\mathrm{Ei}_1\left(-\frac{x^2}{2}\right)}{16}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve
$x^2\left(\frac{d^2}{dx^2}y(x)\right) - x(-x^2+7)\left(\frac{d}{dx}y(x)\right) + 12y(x) = 0$

- Highest derivative means the order of the ODE is 2
  $\frac{d^2}{dx^2}y(x)$
- Isolate 2nd derivative
  $\frac{d^2}{dx^2}y(x) = -\frac{12y(x)}{x^2} - \frac{(x^2-7)\left(\frac{d}{dx}y(x)\right)}{x}$
- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin
  $\frac{d^2}{dx^2}y(x) + \frac{(x^2-7)\left(\frac{d}{dx}y(x)\right)}{x} + \frac{12y(x)}{x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point
  - Define functions

$\left[P_2(x) = \frac{x^2-7}{x}, P_3(x) = \frac{12}{x^2}\right]$

- ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

  $\left.(x \cdot P_2(x))\right|_{x=0} = -7$

- ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $\left.(x^2 \cdot P_3(x))\right|_{x=0} = 12$

- ◦ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $x^2\left(\frac{d^2}{dx^2}y(x)\right) + x(x^2-7)\left(\frac{d}{dx}y(x)\right) + 12y(x) = 0$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

- ◦ Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m = 1..3$

  $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1+m}$

- ◦ Shift index using $k- >k+1-m$

  $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$

- ◦ Convert $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

  $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(-2+r)\,(-6+r)\,x^r + a_1(-1+r)\,(-5+r)\,x^{1+r} + \left(\sum_{k=2}^{\infty} (a_k(k+r-2)\,(k+r-6) + a_{k-2}(k+r\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-2+r)\,(-6+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{2, 6\}$

- Each term must be 0

  $a_1(-1+r)\,(-5+r) = 0$

- Solve for the dependent coefficient(s)

  $a_1 = 0$

- Each term in the series must be 0, giving the recursion relation

  $(k+r-2)\,(a_k(k+r-6) + a_{k-2}) = 0$

- Shift index using $k- >k+2$

  $(k+r)\,(a_{k+2}(k-4+r) + a_k) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{a_k}{k-4+r}$

- Recursion relation for $r = 2$

  $a_{k+2} = -\frac{a_k}{k-2}$

- Series not valid for $r = 2$, division by 0 in the recursion relation at $k = 2$

  $a_{k+2} = -\frac{a_k}{k-2}$

- Recursion relation for $r = 6$

  $a_{k+2} = -\frac{a_k}{k+2}$

- Solution for $r = 6$

$$\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+6}, a_{k+2} = -\frac{a_k}{k+2}, a_1 = 0\right]$$

2.1.184 Problem 186

Internal problem ID [9356]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 186
Date solved : `Monday, January 27, 2025 at 06:01:50 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' + x(2x^2+1)\, y' - (-10x^2+1)\, y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.329 (sec)

Writing the ode as

$$x^2y'' + (2x^3+x)\, y' + (10x^2-1)\, y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= 2x^3 + x \\ C &= 10x^2 - 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{4x^4 - 32x^2 + 3}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 4x^4 - 32x^2 + 3 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{4x^4 - 32x^2 + 3}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.352: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 4 \\ &= -2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = x^2 - 8 + \frac{3}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx x - \frac{4}{x} - \frac{61}{8x^3} - \frac{61}{2x^5} - \frac{19337}{128x^7} - \frac{26779}{32x^9} - \frac{5083557}{1024x^{11}} - \frac{7896633}{256x^{13}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = 1$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= x \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = x^2$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{4x^4 - 32x^2 + 3}{4x^2} \\ &= Q + \frac{R}{4x^2} \\ &= (x^2 - 8) + \left(\frac{3}{4x^2}\right) \\ &= x^2 - 8 + \frac{3}{4x^2} \end{aligned}$$

We see that the coefficient of the term x in the quotient is -8. Now b can be found.

$$\begin{aligned} b &= (-8) - (0) \\ &= -8 \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= x \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-8}{1} - 1\right) &= -\frac{9}{2} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-8}{1} - 1\right) &= \frac{7}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{4x^4 - 32x^2 + 3}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-2	x	$-\frac{9}{2}$	$\frac{7}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{7}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^+\right) \\ &= \frac{7}{2} - \left(\frac{3}{2}\right) \\ &= 2 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{3}{2x} + (-)\,(x) \\ &= \frac{3}{2x} - x \\ &= \frac{3}{2x} - x \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 2$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x^2 + a_1 x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(2) + 2\left(\frac{3}{2x} - x\right)(2x + a_1) + \left(\left(-\frac{3}{2x^2} - 1\right) + \left(\frac{3}{2x} - x\right)^2 - \left(\frac{4x^4 - 32x^2 + 3}{4x^2}\right) \right) = 0$$

$$\frac{2x^2 a_1 + (4a_0 + 8)\,x + 3a_1}{x} = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = -2, a_1 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^2 - 2$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \left(x^2-2\right) \mathrm{e}^{\int \left(\frac{3}{2x}-x\right)dx} \\
&= \left(x^2-2\right) \mathrm{e}^{-\frac{x^2}{2}+\frac{3\ln(x)}{2}} \\
&= \left(x^2-2\right) x^{3/2} \mathrm{e}^{-\frac{x^2}{2}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{2x^3+x}{x^2} \, dx} \\
&= z_1 e^{-\frac{x^2}{2}-\frac{\ln(x)}{2}} \\
&= z_1 \left(\frac{\mathrm{e}^{-\frac{x^2}{2}}}{\sqrt{x}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = x \,\mathrm{e}^{-x^2} \left(x^2-2\right)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{2x^3+x}{x^2} \, dx}}{(y_1)^2} \, dx \\
&= y_1 \int \frac{e^{-x^2-\ln(x)}}{(y_1)^2} \, dx \\
&= y_1 \left(\int \frac{\mathrm{e}^{-x^2-\ln(x)} \mathrm{e}^{2x^2}}{x^2 \left(x^2-2\right)^2} dx\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(x \,\mathrm{e}^{-x^2} \left(x^2-2\right)\right) + c_2 \left(x \,\mathrm{e}^{-x^2} \left(x^2-2\right) \left(\int \frac{\mathrm{e}^{-x^2-\ln(x)} \mathrm{e}^{2x^2}}{x^2 \left(x^2-2\right)^2} dx\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2\left(\frac{d^2}{dx^2}y(x)\right)+x(2x^2+1)\left(\frac{d}{dx}y(x)\right)-(-10x^2+1)\,y(x)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

2.1.185 Problem 187

Internal problem ID [9357]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 187
Date solved : `Monday, January 27, 2025 at 06:01:51 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' + x\left(-2x^2+1\right)y' - 4\left(2x^2+1\right)y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.249 (sec)

Writing the ode as

$$x^2y'' + \left(-2x^3+x\right)y' + \left(-8x^2-4\right)y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -2x^3+x \\ C &= -8x^2-4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{4x^4+24x^2+15}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 4x^4+24x^2+15 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{4x^4+24x^2+15}{4x^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.354: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 4 \\ &= -2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = x^2 + 6 + \frac{15}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{15}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx x + \frac{3}{x} - \frac{21}{8x^3} + \frac{63}{8x^5} - \frac{3465}{128x^7} + \frac{13041}{128x^9} - \frac{417501}{1024x^{11}} + \frac{1744659}{1024x^{13}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = 1$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= x \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = x^2$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{4x^4 + 24x^2 + 15}{4x^2} \\ &= Q + \frac{R}{4x^2} \\ &= (x^2 + 6) + \left(\frac{15}{4x^2}\right) \\ &= x^2 + 6 + \frac{15}{4x^2} \end{aligned}$$

We see that the coefficient of the term x in the quotient is 6. Now b can be found.

$$\begin{aligned} b &= (6) - (0) \\ &= 6 \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= x \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{6}{1} - 1\right) &&= \frac{5}{2} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{6}{1} - 1\right) &&= -\frac{7}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{4x^4 + 24x^2 + 15}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{5}{2}$	$-\frac{3}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-2	x	$\frac{5}{2}$	$-\frac{7}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{5}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^+ - (\alpha_{c_1}^+) \\ &= \frac{5}{2} - \left(\frac{5}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1} \right) + (+)[\sqrt{r}]_\infty \\ &= \frac{5}{2x} + (x) \\ &= \frac{5}{2x} + x \\ &= \frac{5}{2x} + x \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(\frac{5}{2x} + x\right)(0) + \left(\left(-\frac{5}{2x^2} + 1\right) + \left(\frac{5}{2x} + x\right)^2 - \left(\frac{4x^4 + 24x^2 + 15}{4x^2}\right) \right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= e^{\int \left(\frac{5}{2x} + x\right) dx} \\ &= x^{5/2} e^{\frac{x^2}{2}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-2x^3+x}{x^2}\,dx} \\ &= z_1 e^{\frac{x^2}{2}-\frac{\ln(x)}{2}} \\ &= z_1\left(\frac{e^{\frac{x^2}{2}}}{\sqrt{x}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = x^2 e^{x^2}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-2x^3+x}{x^2}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{x^2-\ln(x)}}{(y_1)^2}\,dx \\ &= y_1\left(-\frac{e^{-x^2}}{4x^4}+\frac{e^{-x^2}}{4x^2}-\frac{\mathrm{Ei}_1(x^2)}{4}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(x^2 e^{x^2}\right) + c_2\left(x^2 e^{x^2}\left(-\frac{e^{-x^2}}{4x^4}+\frac{e^{-x^2}}{4x^2}-\frac{\mathrm{Ei}_1(x^2)}{4}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve
$x^2\left(\frac{d^2}{dx^2}y(x)\right) + x(-2x^2+1)\left(\frac{d}{dx}y(x)\right) - 4(2x^2+1)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2
  $\frac{d^2}{dx^2}y(x)$
- Isolate 2nd derivative
  $\frac{d^2}{dx^2}y(x) = \frac{4(2x^2+1)y(x)}{x^2} + \frac{(2x^2-1)\left(\frac{d}{dx}y(x)\right)}{x}$
- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea
  $\frac{d^2}{dx^2}y(x) - \frac{(2x^2-1)\left(\frac{d}{dx}y(x)\right)}{x} - \frac{4(2x^2+1)y(x)}{x^2} = 0$
- □ Check to see if $x_0 = 0$ is a regular singular point
  - ○ Define functions
    $\left[P_2(x) = -\frac{2x^2-1}{x}, P_3(x) = -\frac{4(2x^2+1)}{x^2}\right]$

- $x \cdot P_2(x)$ is analytic at $x=0$

  $\left(x \cdot P_2(x)\right)\Big|_{x=0} = 1$

- $x^2 \cdot P_3(x)$ is analytic at $x=0$

  $\left(x^2 \cdot P_3(x)\right)\Big|_{x=0} = -4$

- $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $x^2\left(\frac{d^2}{dx^2}y(x)\right) - x(2x^2-1)\left(\frac{d}{dx}y(x)\right) + (-8x^2-4)\,y(x) = 0$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

- Convert $x^m \cdot y(x)$ to series expansion for $m = 0..2$

  $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- Shift index using $k->k-m$

  $x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m = 1..3$

  $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$

- Shift index using $k->k+1-m$

  $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$

- Convert $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

  $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\,x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(2+r)(-2+r)x^r + a_1(3+r)(-1+r)x^{1+r} + \left(\sum_{k=2}^{\infty} (a_k(k+r+2)(k+r-2) - 2a_{k-2}(k+r\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(2+r)(-2+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{-2, 2\}$

- Each term must be 0

  $a_1(3+r)(-1+r) = 0$

- Solve for the dependent coefficient(s)

  $a_1 = 0$

- Each term in the series must be 0, giving the recursion relation

  $(k+r+2)(a_k(k+r-2) - 2a_{k-2}) = 0$

- Shift index using $k->k+2$

  $(k+r+4)(a_{k+2}(k+r) - 2a_k) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+2} = \frac{2a_k}{k+r}$

- Recursion relation for $r=-2$

  $a_{k+2} = \frac{2a_k}{k-2}$

- Series not valid for $r=-2$, division by 0 in the recursion relation at $k=2$
  $a_{k+2}=\frac{2a_k}{k-2}$
- Recursion relation for $r=2$
  $a_{k+2}=\frac{2a_k}{k+2}$
- Solution for $r=2$
  $\left[y(x)=\sum_{k=0}^{\infty} a_k x^{k+2}, a_{k+2}=\frac{2a_k}{k+2}, a_1=0\right]$

2.1.186 Problem 188

Internal problem ID [9358]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 188
Date solved : `Monday, January 27, 2025 at 06:01:52 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' + x\left(-3x^2+1\right)y' - 4\left(-3x^2+1\right)y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.580 (sec)

Writing the ode as

$$x^2y'' + \left(-3x^3+x\right)y' + \left(12x^2-4\right)y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -3x^3+x \\ C &= 12x^2-4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{9x^4 - 60x^2 + 15}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 9x^4 - 60x^2 + 15 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{9x^4 - 60x^2 + 15}{4x^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.356: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 4 \\ &= -2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{9x^2}{4} - 15 + \frac{15}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{15}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{3x}{2} - \frac{5}{x} - \frac{85}{12x^3} - \frac{425}{18x^5} - \frac{41225}{432x^7} - \frac{278375}{648x^9} - \frac{1787125}{864x^{11}} - \frac{40534375}{3888x^{13}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{3}{2}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= \frac{3x}{2}\end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{9x^2}{4}$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned}r &= \frac{s}{t} \\ &= \frac{9x^4 - 60x^2 + 15}{4x^2} \\ &= Q + \frac{R}{4x^2} \\ &= \left(\frac{9x^2}{4} - 15\right) + \left(\frac{15}{4x^2}\right) \\ &= \frac{9x^2}{4} - 15 + \frac{15}{4x^2}\end{aligned}$$

We see that the coefficient of the term x in the quotient is -15. Now b can be found.

$$\begin{aligned}b &= (-15) - (0) \\ &= -15\end{aligned}$$

Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= \frac{3x}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) = \frac{1}{2}\left(\frac{-15}{\frac{3}{2}} - 1\right) = -\frac{11}{2} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) = \frac{1}{2}\left(-\frac{-15}{\frac{3}{2}} - 1\right) = \frac{9}{2}\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{9x^4 - 60x^2 + 15}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{5}{2}$	$-\frac{3}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-2	$\frac{3x}{2}$	$-\frac{11}{2}$	$\frac{9}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{9}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^- - (\alpha_{c_1}^+) \\ &= \frac{9}{2} - \left(\frac{5}{2}\right) \\ &= 2 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{5}{2x} + (-)\left(\frac{3x}{2}\right) \\ &= \frac{5}{2x} - \frac{3x}{2} \\ &= \frac{5}{2x} - \frac{3x}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 2$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = x^2 + a_1 x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(2) + 2\left(\frac{5}{2x} - \frac{3x}{2}\right)(2x + a_1) + \left(\left(-\frac{5}{2x^2} - \frac{3}{2}\right) + \left(\frac{5}{2x} - \frac{3x}{2}\right)^2 - \left(\frac{9x^4 - 60x^2 + 15}{4x^2}\right)\right) = 0$$

$$\frac{3x^2 a_1 + 6(2 + a_0)\, x + 5a_1}{x} = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = -2, a_1 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^2 - 2$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= pe^{\int \omega \, dx} \\ &= (x^2 - 2)\, e^{\int \left(\frac{5}{2x} - \frac{3x}{2}\right) dx} \\ &= (x^2 - 2)\, e^{-\frac{3x^2}{4} + \frac{5\ln(x)}{2}} \\ &= (x^2 - 2)\, x^{5/2} e^{-\frac{3x^2}{4}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-3x^3+x}{x^2}\, dx} \\ &= z_1 e^{\frac{3x^2}{4} - \frac{\ln(x)}{2}} \\ &= z_1 \left(\frac{e^{\frac{3x^2}{4}}}{\sqrt{x}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = (x^2 - 2)\, x^2$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-3x^3+x}{x^2}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{\frac{3x^2}{2} - \ln(x)}}{(y_1)^2}\, dx \\ &= y_1 \left(\int \frac{e^{\frac{3x^2}{2} - \ln(x)}}{(x^2 - 2)^2\, x^4} dx\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left((x^2 - 2)\, x^2\right) + c_2\left((x^2 - 2)\, x^2 \left(\int \frac{e^{\frac{3x^2}{2} - \ln(x)}}{(x^2 - 2)^2\, x^4} dx\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2\left(\frac{d^2}{dx^2}y(x)\right)+x(-3x^2+1)\left(\frac{d}{dx}y(x)\right)-4(-3x^2+1)\,y(x)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x)=-\frac{4(3x^2-1)y(x)}{x^2}+\frac{(3x^2-1)\left(\frac{d}{dx}y(x)\right)}{x}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x)-\frac{(3x^2-1)\left(\frac{d}{dx}y(x)\right)}{x}+\frac{4(3x^2-1)y(x)}{x^2}=0$

□ Check to see if $x_0=0$ is a regular singular point

  - Define functions

    $\left[P_2(x)=-\frac{3x^2-1}{x}, P_3(x)=\frac{4(3x^2-1)}{x^2}\right]$

  - $x\cdot P_2(x)$ is analytic at $x=0$

    $\left.(x\cdot P_2(x))\right|_{x=0}=1$

  - $x^2\cdot P_3(x)$ is analytic at $x=0$

    $\left.(x^2\cdot P_3(x))\right|_{x=0}=-4$

  - $x=0$is a regular singular point

  Check to see if $x_0=0$ is a regular singular point

  $x_0=0$

- Multiply by denominators

  $x^2\left(\frac{d^2}{dx^2}y(x)\right)-(3x^2-1)\,x\left(\frac{d}{dx}y(x)\right)+(12x^2-4)\,y(x)=0$

- Assume series solution for $y(x)$

  $y(x)=\sum_{k=0}^{\infty}a_k x^{k+r}$

□ Rewrite ODE with series expansions

  - Convert $x^m\cdot y(x)$ to series expansion for $m=0..2$

    $x^m\cdot y(x)=\sum_{k=0}^{\infty}a_k x^{k+r+m}$

  - Shift index using $k->k-m$

    $x^m\cdot y(x)=\sum_{k=m}^{\infty}a_{k-m}x^{k+r}$

  - Convert $x^m\cdot\left(\frac{d}{dx}y(x)\right)$ to series expansion for $m=1..3$

    $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,x^{k+r-1+m}$

  - Shift index using $k->k+1-m$

    $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,x^{k+r}$

  - Convert $x^2\cdot\left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

    $x^2\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(2+r)\,(-2+r)\,x^r+a_1(3+r)\,(-1+r)\,x^{1+r}+\left(\sum_{k=2}^{\infty}(a_k(k+r+2)\,(k+r-2)-3a_{k-2}(k-6+\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$(2+r)(-2+r)=0$

- Values of r that satisfy the indicial equation

  $r \in \{-2, 2\}$
- Each term must be 0

  $a_1(3+r)(-1+r)=0$
- Solve for the dependent coefficient(s)

  $a_1=0$
- Each term in the series must be 0, giving the recursion relation

  $a_k(k+r+2)(k+r-2)-3a_{k-2}(k-6+r)=0$
- Shift index using $k->k+2$

  $a_{k+2}(k+4+r)(k+r)-3a_k(k+r-4)=0$
- Recursion relation that defines series solution to ODE

  $a_{k+2}=\frac{3a_k(k+r-4)}{(k+4+r)(k+r)}$
- Recursion relation for $r=-2$; series terminates at $k=6$

  $a_{k+2}=\frac{3a_k(k-6)}{(k+2)(k-2)}$
- Series not valid for $r=-2$, division by 0 in the recursion relation at $k=2$

  $a_{k+2}=\frac{3a_k(k-6)}{(k+2)(k-2)}$
- Recursion relation for $r=2$; series terminates at $k=2$

  $a_{k+2}=\frac{3a_k(k-2)}{(k+6)(k+2)}$
- Solution for $r=2$

  $\left[y(x)=\sum_{k=0}^{\infty} a_k x^{k+2}, a_{k+2}=\frac{3a_k(k-2)}{(k+6)(k+2)}, a_1=0\right]$

CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2\left(x^2+1\right)y''+x\left(11x^2+5\right)y'+24x^2y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.380 (sec)

Writing the ode as

$$\left(x^4+x^2\right)y''+\left(11x^3+5x\right)y'+24x^2y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=x^4+x^2\\B&=11x^3+5x\\C&=24x^2\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned}r&=\frac{s}{t}\\&=\frac{2AB'-2BA'+B^2-4AC}{4A^2}\end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{3x^4+6x^2+15}{4\left(x^3+x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned}s&=3x^4+6x^2+15\\t&=4\left(x^3+x\right)^2\end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{3x^4+6x^2+15}{4\left(x^3+x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.358: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 4 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^3+x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = i$ of order 2. There is a pole at $x = -i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{3}{4(x-i)^2} + \frac{3}{4(x+i)^2} + \frac{9i}{4(x-i)} - \frac{9i}{4(x+i)} + \frac{15}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{15}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{2} \end{aligned}$$

For the pole at $x = i$ let b be the coefficient of $\frac{1}{(x-i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

For the pole at $x = -i$ let b be the coefficient of $\frac{1}{(x+i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = \frac{3x^4 + 6x^2 + 15}{4\left(x^3 + x\right)^2}
$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{3}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{3x^4 + 6x^2 + 15}{4\left(x^3 + x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{5}{2}$	$-\frac{3}{2}$
i	2	0	$\frac{3}{2}$	$-\frac{1}{2}$
$-i$	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{3}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^- + \alpha_{c_2}^+ + \alpha_{c_3}^+\right) \\
&= \frac{3}{2} - \left(\frac{3}{2}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

Substituting the above values in the above results in

$$\begin{aligned}\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x-c_2}\right) + \left((+)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^+}{x-c_3}\right) + (+)[\sqrt{r}]_\infty \\ &= -\frac{3}{2x} + \frac{3}{2(x-i)} + \frac{3}{2(x+i)} + (0) \\ &= -\frac{3}{2x} + \frac{3}{2(x-i)} + \frac{3}{2(x+i)} \\ &= -\frac{3}{2x} + \frac{3x}{x^2+1}\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{3}{2x} + \frac{3}{2(x-i)} + \frac{3}{2(x+i)}\right)(0) + \left(\left(\frac{3}{2x^2} - \frac{3}{2(x-i)^2} - \frac{3}{2(x+i)^2}\right) + \left(-\frac{3}{2x} + \frac{3}{2(x-i)} + \frac{3}{2(x$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}z_1(x) &= pe^{\int \omega\, dx} \\ &= e^{\int \left(-\frac{3}{2x} + \frac{3}{2(x-i)} + \frac{3}{2(x+i)}\right) dx} \\ &= \frac{(x^2+1)^{3/2}}{x^{3/2}}\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{11x^3+5x}{x^4+x^2}\, dx} \\ &= z_1 e^{-\frac{5\ln(x)}{2} - \frac{3\ln(x^2+1)}{2}} \\ &= z_1 \left(\frac{1}{x^{5/2}(x^2+1)^{3/2}}\right)\end{aligned}$$

Which simplifies to

$$y_1 = \frac{1}{x^4}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}y_2 &= y_1 \int \frac{e^{\int -\frac{11x^3+5x}{x^4+x^2}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-5\ln(x) - 3\ln(x^2+1)}}{(y_1)^2}\, dx \\ &= y_1 \left(-\frac{(x^2+1)(2x^2+1)\, x^5 e^{-5\ln(x) - 3\ln(x^2+1)}}{4}\right)\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{1}{x^4}\right) + c_2 \left(\frac{1}{x^4}\left(-\frac{(x^2+1)(2x^2+1)\,x^5 \mathrm{e}^{-5\ln(x)-3\ln(x^2+1)}}{4}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2(x^2+1)\left(\frac{d^2}{dx^2}y(x)\right) + x(11x^2+5)\left(\frac{d}{dx}y(x)\right) + 24x^2 y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{24y(x)}{x^2+1} - \frac{(11x^2+5)\left(\frac{d}{dx}y(x)\right)}{x(x^2+1)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x) + \frac{(11x^2+5)\left(\frac{d}{dx}y(x)\right)}{x(x^2+1)} + \frac{24y(x)}{x^2+1} = 0$

- □ Check to see if x_0 is a regular singular point
  - Define functions

    $\left[P_2(x) = \frac{11x^2+5}{x(x^2+1)}, P_3(x) = \frac{24}{x^2+1}\right]$

  - $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left.(x \cdot P_2(x))\right|_{x=0} = 5$

  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $\left.(x^2 \cdot P_3(x))\right|_{x=0} = 0$

  - $x = 0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $x(x^2+1)\left(\frac{d^2}{dx^2}y(x)\right) + (11x^2+5)\left(\frac{d}{dx}y(x)\right) + 24xy(x) = 0$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

- □ Rewrite ODE with series expansions
  - Convert $x \cdot y(x)$ to series expansion

    $x \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+1}$

  - Shift index using $k->k-1$

    $x \cdot y(x) = \sum_{k=1}^{\infty} a_{k-1} x^{k+r}$

  - Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m = 0..2$

    $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r-1+m}$

  - Shift index using $k->k+1-m$

$x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$

- Convert $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m = 1..3$

  $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-2+m}$

- Shift index using $k->k+2-m$

  $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0 r(4+r)\, x^{-1+r} + a_1(1+r)\,(5+r)\, x^r + \left(\sum_{k=1}^{\infty} (a_{k+1}(k+r+1)\,(k+5+r) + a_{k-1}(k+5+r)\,(k+3\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r(4+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{-4, 0\}$

- Each term must be 0

  $a_1(1+r)\,(5+r) = 0$

- Each term in the series must be 0, giving the recursion relation

  $(k+5+r)\,(a_{k+1}(k+r+1) + a_{k-1}(k+3+r)) = 0$

- Shift index using $k->k+1$

  $(k+r+6)\,(a_{k+2}(k+2+r) + a_k(k+r+4)) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{a_k(k+r+4)}{k+2+r}$

- Recursion relation for $r = -4$

  $a_{k+2} = -\frac{a_k k}{k-2}$

- Series not valid for $r = -4$, division by 0 in the recursion relation at $k = 2$

  $a_{k+2} = -\frac{a_k k}{k-2}$

- Recursion relation for $r = 0$

  $a_{k+2} = -\frac{a_k(k+4)}{k+2}$

- Solution for $r = 0$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^k, a_{k+2} = -\frac{a_k(k+4)}{k+2}, 5a_1 = 0\right]$

2.1.188 Problem 190

Internal problem ID [9360]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 190
Date solved : `Monday, January 27, 2025 at 06:01:53 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$4x^2\left(x^2+1\right)y''+8xy'-\left(-x^2+35\right)y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.334 (sec)

Writing the ode as

$$\left(4x^4+4x^2\right)y''+8xy'+\left(x^2-35\right)y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A&=4x^4+4x^2\\ B&=8x \\ C&=x^2-35 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r&=\frac{s}{t} \\ &=\frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{-x^4+22x^2+35}{4\left(x^3+x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s&=-x^4+22x^2+35\\ t&=4\left(x^3+x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{-x^4+22x^2+35}{4\left(x^3+x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.360: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 4 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^3 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = i$ of order 2. There is a pole at $x = -i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{35}{4x^2} + \frac{3}{4\,(x-i)^2} + \frac{3}{4\,(x+i)^2} + \frac{21i}{4\,(x-i)} - \frac{21i}{4\,(x+i)}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{35}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{5}{2} \end{aligned}$$

For the pole at $x = i$ let b be the coefficient of $\frac{1}{(x-i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

For the pole at $x = -i$ let b be the coefficient of $\frac{1}{(x+i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0\\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2}\\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = \frac{-x^4 + 22x^2 + 35}{4\left(x^3+x\right)^2}
$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{1}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0\\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2}\\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{-x^4 + 22x^2 + 35}{4\left(x^3+x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{7}{2}$	$-\frac{5}{2}$
i	2	0	$\frac{3}{2}$	$-\frac{1}{2}$
$-i$	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^+ + \alpha_{c_3}^+\right)\\
&= \frac{1}{2} - \left(\frac{1}{2}\right)\\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x-c_1}\right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{+}}{x-c_2}\right) + \left((+)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^{+}}{x-c_3}\right) + (-)[\sqrt{r}]_{\infty} \\
&= -\frac{5}{2x} + \frac{3}{2\left(x-i\right)} + \frac{3}{2\left(x+i\right)} + (-)\left(0\right) \\
&= -\frac{5}{2x} + \frac{3}{2\left(x-i\right)} + \frac{3}{2\left(x+i\right)} \\
&= -\frac{5}{2x} + \frac{3x}{x^2+1}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(0) + 2\left(-\frac{5}{2x} + \frac{3}{2\left(x-i\right)} + \frac{3}{2\left(x+i\right)}\right)(0) + \left(\left(\frac{5}{2x^2} - \frac{3}{2\left(x-i\right)^2} - \frac{3}{2\left(x+i\right)^2}\right) + \left(-\frac{5}{2x} + \frac{3}{2\left(x-i\right)} + \right.\right.
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(-\frac{5}{2x} + \frac{3}{2(x-i)} + \frac{3}{2(x+i)}\right) dx} \\
&= \frac{\left(x^2+1\right)^{3/2}}{x^{5/2}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{8x}{4x^4+4x^2}\, dx} \\
&= z_1 e^{\frac{\ln\left(x^2+1\right)}{2} - \ln(x)} \\
&= z_1 \left(\frac{\sqrt{x^2+1}}{x}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{\left(x^2+1\right)^2}{x^{7/2}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{8x}{4x^4+4x^2}\, dx}}{\left(y_1\right)^2}\, dx \\
&= y_1 \int \frac{e^{\ln\left(x^2+1\right) - 2\ln(x)}}{\left(y_1\right)^2}\, dx \\
&= y_1 \left(\frac{1}{x^2+1} - \frac{1}{4\left(x^2+1\right)^2} + \frac{\ln\left(x^2+1\right)}{2}\right)
\end{aligned}
$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\frac{(x^2+1)^2}{x^{7/2}} \right) + c_2 \left(\frac{(x^2+1)^2}{x^{7/2}} \left(\frac{1}{x^2+1} - \frac{1}{4(x^2+1)^2} + \frac{\ln(x^2+1)}{2} \right) \right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$4x^2(x^2+1)\left(\frac{d^2}{dx^2}y(x)\right) + 8x\left(\frac{d}{dx}y(x)\right) - (-x^2+35)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{(x^2-35)y(x)}{4x^2(x^2+1)} - \frac{2\left(\frac{d}{dx}y(x)\right)}{x(x^2+1)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x) + \frac{2\left(\frac{d}{dx}y(x)\right)}{x(x^2+1)} + \frac{(x^2-35)y(x)}{4x^2(x^2+1)} = 0$

- □ Check to see if x_0 is a regular singular point
  - ◦ Define functions

    $\left[P_2(x) = \frac{2}{(x^2+1)x}, P_3(x) = \frac{x^2-35}{4x^2(x^2+1)}\right]$

  - ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left.(x \cdot P_2(x))\right|_{x=0} = 2$

  - ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $\left.(x^2 \cdot P_3(x))\right|_{x=0} = -\frac{35}{4}$

  - ◦ $x = 0$is a regular singular point

    Check to see if x_0 is a regular singular point

    $x_0 = 0$

- Multiply by denominators

  $4x^2(x^2+1)\left(\frac{d^2}{dx^2}y(x)\right) + 8x\left(\frac{d}{dx}y(x)\right) + (x^2-35)\,y(x) = 0$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

- □ Rewrite ODE with series expansions
  - ◦ Convert $x^m \cdot y(x)$ to series expansion for $m = 0..2$

    $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

  - ◦ Shift index using $k- >k-m$

    $x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

  - ◦ Convert $x \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion

    $x \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r}$

  - ◦ Convert $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m = 2..4$

$$x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, x^{k+r-2+m}$$

- Shift index using $k->k+2-m$

$$x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0(7+2r)(-5+2r)\, x^r + a_1(9+2r)(-3+2r)\, x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(2k+2r+7)(2k+2r-5) + a_k\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $(7+2r)(-5+2r) = 0$
- Values of r that satisfy the indicial equation
  $r \in \left\{-\frac{7}{2}, \frac{5}{2}\right\}$
- Each term must be 0
  $a_1(9+2r)(-3+2r) = 0$
- Solve for the dependent coefficient(s)
  $a_1 = 0$
- Each term in the series must be 0, giving the recursion relation
  $4\left(k-\frac{5}{2}+r\right)\left(\left(k-\frac{5}{2}+r\right)a_{k-2} + a_k\left(k+r+\frac{7}{2}\right)\right) = 0$
- Shift index using $k->k+2$
  $4\left(k-\frac{1}{2}+r\right)\left(\left(k-\frac{1}{2}+r\right)a_k + a_{k+2}\left(k+\frac{11}{2}+r\right)\right) = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+2} = -\frac{(2k+2r-1)a_k}{2k+11+2r}$
- Recursion relation for $r = -\frac{7}{2}$; series terminates at $k = 4$
  $a_{k+2} = -\frac{(2k-8)a_k}{2k+4}$
- Solution for $r = -\frac{7}{2}$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k-\frac{7}{2}}, a_{k+2} = -\frac{(2k-8)a_k}{2k+4}, a_1 = 0\right]$
- Recursion relation for $r = \frac{5}{2}$
  $a_{k+2} = -\frac{(2k+4)a_k}{2k+16}$
- Solution for $r = \frac{5}{2}$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+\frac{5}{2}}, a_{k+2} = -\frac{(2k+4)a_k}{2k+16}, a_1 = 0\right]$
- Combine solutions and rename parameters
  $\left[y(x) = \left(\sum_{k=0}^{\infty} a_k x^{k-\frac{7}{2}}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{5}{2}}\right), a_{k+2} = -\frac{(2k-8)a_k}{2k+4}, a_1 = 0, b_{k+2} = -\frac{(2k+4)b_k}{2k+16}, b_1 = 0\right]$

2.1.189 Problem 191

Internal problem ID [9361]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 191
Date solved : Monday, January 27, 2025 at 06:01:54 PM
CAS classification : [[_2nd_order, _with_linear_symmetries]]

Solve

$$x^2\left(x^2+1\right)y''-x\left(-x^2+5\right)y'-\left(25x^2+7\right)y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.354 (sec)

Writing the ode as

$$\left(x^4+x^2\right)y''+\left(x^3-5x\right)y'+\left(-25x^2-7\right)y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^4+x^2 \\ B &= x^3-5x \\ C &= -25x^2-7 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{99x^4+150x^2+63}{4\left(x^3+x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 99x^4+150x^2+63 \\ t &= 4\left(x^3+x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{99x^4+150x^2+63}{4\left(x^3+x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.362: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 4 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^3 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = i$ of order 2. There is a pole at $x = -i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{3}{4\,(x-i)^2} + \frac{3}{4\,(x+i)^2} - \frac{15i}{4\,(x-i)} + \frac{15i}{4\,(x+i)} + \frac{63}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{63}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{9}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{7}{2} \end{aligned}$$

For the pole at $x = i$ let b be the coefficient of $\frac{1}{(x-i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

For the pole at $x = -i$ let b be the coefficient of $\frac{1}{(x+i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{99x^4 + 150x^2 + 63}{4\left(x^3 + x\right)^2}$$

Since the $\gcd(s, t) = 1$. This gives $b = \frac{99}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{11}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{9}{2}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{99x^4 + 150x^2 + 63}{4\left(x^3 + x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{9}{2}$	$-\frac{7}{2}$
i	2	0	$\frac{3}{2}$	$-\frac{1}{2}$
$-i$	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{11}{2}$	$-\frac{9}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -\frac{9}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^- + \alpha_{c_3}^-\right) \\
&= -\frac{9}{2} - \left(-\frac{9}{2}\right) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2}\right) + \left((-)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^-}{x-c_3}\right) + (-)[\sqrt{r}]_\infty \\ &= -\frac{7}{2x} - \frac{1}{2(x-i)} - \frac{1}{2(x+i)} + (-)(0) \\ &= -\frac{7}{2x} - \frac{1}{2(x-i)} - \frac{1}{2(x+i)} \\ &= -\frac{7}{2x} - \frac{x}{x^2+1}\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{7}{2x} - \frac{1}{2(x-i)} - \frac{1}{2(x+i)}\right)(0) + \left(\left(\frac{7}{2x^2} + \frac{1}{2(x-i)^2} + \frac{1}{2(x+i)^2}\right) + \left(-\frac{7}{2x} - \frac{1}{2(x-i)} - \frac{1}{2(x$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}z_1(x) &= p e^{\int \omega\, dx} \\ &= e^{\int \left(-\frac{7}{2x} - \frac{1}{2(x-i)} - \frac{1}{2(x+i)}\right) dx} \\ &= \frac{1}{\sqrt{x^2+1}\, x^{7/2}}\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{x^3-5x}{x^4+x^2}\, dx} \\ &= z_1 e^{-\frac{3\ln(x^2+1)}{2} + \frac{5\ln(x)}{2}} \\ &= z_1 \left(\frac{x^{5/2}}{(x^2+1)^{3/2}}\right)\end{aligned}$$

Which simplifies to

$$y_1 = \frac{1}{(x^2+1)^2\, x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}y_2 &= y_1 \int \frac{e^{\int -\frac{x^3-5x}{x^4+x^2}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-3\ln(x^2+1)+5\ln(x)}}{(y_1)^2}\, dx \\ &= y_1 \left(\frac{x^3(4x^2+5)\,(x^2+1)^3\, e^{-3\ln(x^2+1)+5\ln(x)}}{40}\right)\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{1}{\left(x^2+1\right)^2 x}\right) + c_2\left(\frac{1}{\left(x^2+1\right)^2 x}\left(\frac{x^3(4x^2+5)\left(x^2+1\right)^3 \mathrm{e}^{-3\ln(x^2+1)+5\ln(x)}}{40}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve
$x^2(x^2+1)\left(\frac{d^2}{dx^2}y(x)\right) - x(-x^2+5)\left(\frac{d}{dx}y(x)\right) - (25x^2+7)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2
  $\frac{d^2}{dx^2}y(x)$
- Isolate 2nd derivative
  $\frac{d^2}{dx^2}y(x) = \frac{(25x^2+7)y(x)}{x^2(x^2+1)} - \frac{(x^2-5)\left(\frac{d}{dx}y(x)\right)}{x(x^2+1)}$
- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin
  $\frac{d^2}{dx^2}y(x) + \frac{(x^2-5)\left(\frac{d}{dx}y(x)\right)}{x(x^2+1)} - \frac{(25x^2+7)y(x)}{x^2(x^2+1)} = 0$
- □ Check to see if x_0 is a regular singular point
  - ○ Define functions
    $\left[P_2(x) = \frac{x^2-5}{x(x^2+1)}, P_3(x) = -\frac{25x^2+7}{x^2(x^2+1)}\right]$
  - ○ $x \cdot P_2(x)$ is analytic at $x=0$
    $\left.(x \cdot P_2(x))\right|_{x=0} = -5$
  - ○ $x^2 \cdot P_3(x)$ is analytic at $x=0$
    $\left.(x^2 \cdot P_3(x))\right|_{x=0} = -7$
  - ○ $x = 0$is a regular singular point
    Check to see if x_0 is a regular singular point
    $x_0 = 0$
- Multiply by denominators
  $x^2(x^2+1)\left(\frac{d^2}{dx^2}y(x)\right) + x(x^2-5)\left(\frac{d}{dx}y(x)\right) + (-25x^2-7)\,y(x) = 0$
- Assume series solution for $y(x)$
  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$
- □ Rewrite ODE with series expansions
  - ○ Convert $x^m \cdot y(x)$ to series expansion for $m = 0..2$
    $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$
  - ○ Shift index using $k->k-m$
    $x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$
  - ○ Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m = 1..3$
    $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r-1+m}$
  - ○ Shift index using $k->k+1-m$

$$x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$$

- Convert $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m = 2..4$

$$x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-2+m}$$

- Shift index using $k- > k+2-m$

$$x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0(1+r)\,(-7+r)\, x^r + a_1(2+r)\,(-6+r)\, x^{1+r} + \left(\sum_{k=2}^{\infty} (a_k(k+r+1)\,(k+r-7) + a_{k-2}(k+3+r$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
$(1+r)\,(-7+r) = 0$
- Values of r that satisfy the indicial equation
$r \in \{-1, 7\}$
- Each term must be 0
$a_1(2+r)\,(-6+r) = 0$
- Solve for the dependent coefficient(s)
$a_1 = 0$
- Each term in the series must be 0, giving the recursion relation
$(k+r-7)\,(a_k(k+r+1) + a_{k-2}(k+3+r)) = 0$
- Shift index using $k- > k+2$
$(k+r-5)\,(a_{k+2}(k+3+r) + a_k(k+r+5)) = 0$
- Recursion relation that defines series solution to ODE
$a_{k+2} = -\frac{a_k(k+r+5)}{k+3+r}$
- Recursion relation for $r = -1$
$a_{k+2} = -\frac{a_k(k+4)}{k+2}$
- Solution for $r = -1$
$\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k-1}, a_{k+2} = -\frac{a_k(k+4)}{k+2}, a_1 = 0\right]$
- Recursion relation for $r = 7$
$a_{k+2} = -\frac{a_k(k+12)}{k+10}$
- Solution for $r = 7$
$\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+7}, a_{k+2} = -\frac{a_k(k+12)}{k+10}, a_1 = 0\right]$
- Combine solutions and rename parameters
$\left[y(x) = \left(\sum_{k=0}^{\infty} a_k x^{k-1}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+7}\right), a_{k+2} = -\frac{a_k(4+k)}{k+2}, a_1 = 0, b_{k+2} = -\frac{b_k(k+12)}{k+10}, b_1 = 0\right]$

2.1.190 Problem 192

Internal problem ID [9362]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 192
Date solved : `Monday, January 27, 2025 at 06:01:55 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2(x^2+1)\, y''+x(2x^2+5)\, y'-21y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.324 (sec)

Writing the ode as

$$(x^4+x^2)\, y''+(2x^3+5x)\, y'-21y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^4+x^2 \\ B &= 2x^3+5x \\ C &= -21 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r=\frac{78x^2+99}{4\,(x^3+x)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 78x^2+99 \\ t &= 4(x^3+x)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{78x^2+99}{4\,(x^3+x)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.364: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 2 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^3+x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = i$ of order 2. There is a pole at $x = -i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{99}{4x^2} + \frac{21}{16\,(x-i)^2} + \frac{21}{16\,(x+i)^2} + \frac{219i}{16\,(x-i)} - \frac{219i}{16\,(x+i)}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{99}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{11}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{9}{2} \end{aligned}$$

For the pole at $x = i$ let b be the coefficient of $\frac{1}{(x-i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{21}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{4} \end{aligned}$$

For the pole at $x = -i$ let b be the coefficient of $\frac{1}{(x+i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{21}{16}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{4} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{4}
\end{aligned}
$$

Since the order of r at ∞ is $4 > 2$ then

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= 0 \\
\alpha_\infty^- &= 1
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{78x^2 + 99}{4(x^3 + x)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{11}{2}$	$-\frac{9}{2}$
i	2	0	$\frac{7}{4}$	$-\frac{3}{4}$
$-i$	2	0	$\frac{7}{4}$	$-\frac{3}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$ then

$$
\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^+ + \alpha_{c_3}^+\right) \\
&= 1 - (-1) \\
&= 2
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x - c_1} \right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x - c_2} \right) + \left((+)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^+}{x - c_3} \right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{9}{2x} + \frac{7}{4(x-i)} + \frac{7}{4(x+i)} + (-)(0) \\
&= -\frac{9}{2x} + \frac{7}{4(x-i)} + \frac{7}{4(x+i)} \\
&= -\frac{9}{2x} + \frac{7x}{2x^2+2}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 2$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = x^2 + a_1 x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(2) + 2\left(-\frac{9}{2x} + \frac{7}{4(x-i)} + \frac{7}{4(x+i)}\right)(2x + a_1) + \left(\left(\frac{9}{2x^2} - \frac{7}{4(x-i)^2} - \frac{7}{4(x+i)^2}\right) + \left(-\frac{9}{2x} + \frac{7}{4(x-\right.\right.$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 8, a_1 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^2 + 8$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= (x^2 + 8)\, e^{\int \left(-\frac{9}{2x} + \frac{7}{4(x-i)} + \frac{7}{4(x+i)}\right) dx} \\ &= (x^2 + 8)\, e^{\frac{7\ln(x^2+1)}{4} - \frac{9\ln(x)}{2}} \\ &= \frac{(x^2 + 8)(x^2 + 1)^{7/4}}{x^{9/2}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{2x^3+5x}{x^4+x^2} \, dx} \\ &= z_1 e^{\frac{3\ln(x^2+1)}{4} - \frac{5\ln(x)}{2}} \\ &= z_1 \left(\frac{(x^2 + 1)^{3/4}}{x^{5/2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{(x^2 + 1)^{5/2}(x^2 + 8)}{x^7}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{2x^3+5x}{x^4+x^2} \, dx}}{(y_1)^2} \, dx \\ &= y_1 \int \frac{e^{\frac{3\ln(x^2+1)}{2} - 5\ln(x)}}{(y_1)^2} \, dx \\ &= y_1 \left(-\frac{(35x^6 + 140x^4 + 168x^2 + 64)\, x^5 e^{\frac{3\ln(x^2+1)}{2} - 5\ln(x)}}{35 (x^2 + 1)^4 (x^2 + 8)}\right) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{(x^2+1)^{5/2}(x^2+8)}{x^7}\right) \\
&\quad + c_2\left(\frac{(x^2+1)^{5/2}(x^2+8)}{x^7}\left(-\frac{(35x^6+140x^4+168x^2+64)\,x^5 \mathrm{e}^{\frac{3\ln(x^2+1)}{2}-5\ln(x)}}{35(x^2+1)^4(x^2+8)}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2(x^2+1)\left(\frac{d^2}{dx^2}y(x)\right)+x(2x^2+5)\left(\frac{d}{dx}y(x)\right)-21y(x)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x)=\frac{21y(x)}{x^2(x^2+1)}-\frac{(2x^2+5)\left(\frac{d}{dx}y(x)\right)}{x(x^2+1)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x)+\frac{(2x^2+5)\left(\frac{d}{dx}y(x)\right)}{x(x^2+1)}-\frac{21y(x)}{x^2(x^2+1)}=0$

☐ Check to see if x_0 is a regular singular point

  - Define functions

    $\left[P_2(x)=\frac{2x^2+5}{x(x^2+1)}, P_3(x)=-\frac{21}{x^2(x^2+1)}\right]$

  - $x\cdot P_2(x)$ is analytic at $x=0$

    $\left.(x\cdot P_2(x))\right|_{x=0}=5$

  - $x^2\cdot P_3(x)$ is analytic at $x=0$

    $\left.(x^2\cdot P_3(x))\right|_{x=0}=-21$

  - $x=0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=0$

- Multiply by denominators

  $x^2(x^2+1)\left(\frac{d^2}{dx^2}y(x)\right)+x(2x^2+5)\left(\frac{d}{dx}y(x)\right)-21y(x)=0$

- Assume series solution for $y(x)$

  $y(x)=\sum_{k=0}^{\infty}a_k x^{k+r}$

☐ Rewrite ODE with series expansions

  - Convert $x^m\cdot\left(\frac{d}{dx}y(x)\right)$ to series expansion for $m=1..3$

    $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,x^{k+r-1+m}$

  - Shift index using $k->k+1-m$

    $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,x^{k+r}$

  - Convert $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m=2..4$

$$x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, x^{k+r-2+m}$$

- Shift index using $k->k+2-m$

$$x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0(7+r)(-3+r)\, x^r + a_1(8+r)(-2+r)\, x^{1+r} + \left(\sum_{k=2}^{\infty} (a_k(k+r+7)(k+r-3) + a_{k-2}(k-2$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $(7+r)(-3+r) = 0$
- Values of r that satisfy the indicial equation
  $r \in \{-7, 3\}$
- Each term must be 0
  $a_1(8+r)(-2+r) = 0$
- Solve for the dependent coefficient(s)
  $a_1 = 0$
- Each term in the series must be 0, giving the recursion relation
  $a_k(k+r+7)(k+r-3) + a_{k-2}(k-2+r)(k+r-1) = 0$
- Shift index using $k->k+2$
  $a_{k+2}(k+9+r)(k+r-1) + a_k(k+r)(k+r+1) = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+2} = -\frac{a_k(k+r)(k+r+1)}{(k+9+r)(k+r-1)}$
- Recursion relation for $r = -7$; series terminates at $k = 6$
  $a_{k+2} = -\frac{a_k(k-7)(k-6)}{(k+2)(k-8)}$
- Solution for $r = -7$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k-7}, a_{k+2} = -\frac{a_k(k-7)(k-6)}{(k+2)(k-8)}, a_1 = 0\right]$
- Recursion relation for $r = 3$
  $a_{k+2} = -\frac{a_k(k+3)(k+4)}{(k+12)(k+2)}$
- Solution for $r = 3$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+3}, a_{k+2} = -\frac{a_k(k+3)(k+4)}{(k+12)(k+2)}, a_1 = 0\right]$
- Combine solutions and rename parameters
  $\left[y(x) = \left(\sum_{k=0}^{\infty} a_k x^{k-7}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+3}\right), a_{k+2} = -\frac{a_k(k-7)(k-6)}{(k+2)(k-8)}, a_1 = 0, b_{k+2} = -\frac{b_k(k+3)(4+k)}{(k+12)(k+2)}, b_1 = 0\right.$

2.1.191 Problem 193

Internal problem ID [9363]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 193
Date solved : `Monday, January 27, 2025 at 06:01:56 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$4x^2\left(x^2+1\right)y''+4x\left(x^2+2\right)y'-\left(x^2+15\right)y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.249 (sec)

Writing the ode as

$$\left(4x^4+4x^2\right)y''+\left(4x^3+8x\right)y'+\left(-x^2-15\right)y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4x^4+4x^2 \\ B &= 4x^3+8x \\ C &= -x^2-15 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r=\frac{10x^2+15}{4\left(x^3+x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 10x^2+15 \\ t &= 4\left(x^3+x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{10x^2+15}{4\left(x^3+x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.366: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 2 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^3 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = i$ of order 2. There is a pole at $x = -i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{15}{4x^2} + \frac{5}{16\,(x-i)^2} + \frac{5}{16\,(x+i)^2} + \frac{35i}{16\,(x-i)} - \frac{35i}{16\,(x+i)}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{15}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{2} \end{aligned}$$

For the pole at $x = i$ let b be the coefficient of $\frac{1}{(x-i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{5}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{4} \end{aligned}$$

For the pole at $x = -i$ let b be the coefficient of $\frac{1}{(x+i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{5}{16}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{4} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{4}
\end{aligned}
$$

Since the order of r at ∞ is $4 > 2$ then

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= 0 \\
\alpha_\infty^- &= 1
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{10x^2 + 15}{4(x^3 + x)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{5}{2}$	$-\frac{3}{2}$
i	2	0	$\frac{5}{4}$	$-\frac{1}{4}$
$-i$	2	0	$\frac{5}{4}$	$-\frac{1}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$ then

$$
\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^+ + \alpha_{c_3}^+\right) \\
&= 1 - (1) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x - c_1} \right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x - c_2} \right) + \left((+)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^+}{x - c_3} \right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{3}{2x} + \frac{5}{4(x-i)} + \frac{5}{4(x+i)} + (-)(0) \\
&= -\frac{3}{2x} + \frac{5}{4(x-i)} + \frac{5}{4(x+i)} \\
&= -\frac{3}{2x} + \frac{5x}{2x^2 + 2}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p''+2\omega p'+\left(\omega'+\omega^2-r\right)p=0 \tag{1A}$$

Let

$$p(x)=1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(-\frac{3}{2x}+\frac{5}{4(x-i)}+\frac{5}{4(x+i)}\right)(0)+\left(\left(\frac{3}{2x^2}-\frac{5}{4(x-i)^2}-\frac{5}{4(x+i)^2}\right)+\left(-\frac{3}{2x}+\frac{5}{4(x-i)}+\frac{5}{4(x\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z''=rz$ is

$$\begin{aligned}
z_1(x)&=pe^{\int \omega\,dx}\\
&=e^{\int\left(-\frac{3}{2x}+\frac{5}{4(x-i)}+\frac{5}{4(x+i)}\right)dx}\\
&=\frac{(x^2+1)^{5/4}}{x^{3/2}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1&=z_1e^{\int -\frac{1}{2}\frac{B}{A}\,dx}\\
&=z_1e^{-\int \frac{1}{2}\frac{4x^3+8x}{4x^4+4x^2}\,dx}\\
&=z_1e^{-\ln(x)+\frac{\ln\left(x^2+1\right)}{4}}\\
&=z_1\left(\frac{(x^2+1)^{1/4}}{x}\right)
\end{aligned}$$

Which simplifies to

$$y_1=\frac{(x^2+1)^{3/2}}{x^{5/2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2=y_1\int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2&=y_1\int \frac{e^{\int -\frac{4x^3+8x}{4x^4+4x^2}\,dx}}{(y_1)^2}\,dx\\
&=y_1\int \frac{e^{-2\ln(x)+\frac{\ln\left(x^2+1\right)}{2}}}{(y_1)^2}\,dx\\
&=y_1\left(-\frac{(3x^2+2)\,x^2e^{-2\ln(x)+\frac{\ln\left(x^2+1\right)}{2}}}{3\,(x^2+1)^2}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y&=c_1y_1+c_2y_2\\
&=c_1\left(\frac{(x^2+1)^{3/2}}{x^{5/2}}\right)+c_2\left(\frac{(x^2+1)^{3/2}}{x^{5/2}}\left(-\frac{(3x^2+2)\,x^2e^{-2\ln(x)+\frac{\ln\left(x^2+1\right)}{2}}}{3\,(x^2+1)^2}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$4x^2(x^2+1)\left(\frac{d^2}{dx^2}y(x)\right)+4x(x^2+2)\left(\frac{d}{dx}y(x)\right)-(x^2+15)\,y(x)=0$

$x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,x^{k+r}$

- ◦ Convert $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m=2..4$

$x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,x^{k+r-2+m}$

- ◦ Shift index using $k->k+2-m$

$x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=-2+m}^{\infty}a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$

Rewrite ODE with series expansions

$$a_0(5+2r)(-3+2r)x^r + a_1(7+2r)(-1+2r)x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(2k+2r+5)(2k+2r-3) + a_{k-2}(\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $(5+2r)(-3+2r) = 0$
- Values of r that satisfy the indicial equation
  $r \in \left\{-\frac{5}{2}, \frac{3}{2}\right\}$
- Each term must be 0
  $a_1(7+2r)(-1+2r) = 0$
- Solve for the dependent coefficient(s)
  $a_1 = 0$
- Each term in the series must be 0, giving the recursion relation
  $4\left(\left(k-\frac{5}{2}+r\right)a_{k-2} + \left(k+r+\frac{5}{2}\right)a_k\right)\left(k+r-\frac{3}{2}\right) = 0$
- Shift index using $k- >k+2$
  $4\left(\left(k-\frac{1}{2}+r\right)a_k + \left(k+\frac{9}{2}+r\right)a_{k+2}\right)\left(k+\frac{1}{2}+r\right) = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+2} = -\frac{(2k+2r-1)a_k}{2k+9+2r}$
- Recursion relation for $r = -\frac{5}{2}$
  $a_{k+2} = -\frac{(2k-6)a_k}{2k+4}$
- Solution for $r = -\frac{5}{2}$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k-\frac{5}{2}}, a_{k+2} = -\frac{(2k-6)a_k}{2k+4}, a_1 = 0\right]$
- Recursion relation for $r = \frac{3}{2}$
  $a_{k+2} = -\frac{(2k+2)a_k}{2k+12}$
- Solution for $r = \frac{3}{2}$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+\frac{3}{2}}, a_{k+2} = -\frac{(2k+2)a_k}{2k+12}, a_1 = 0\right]$
- Combine solutions and rename parameters
  $\left[y(x) = \left(\sum_{k=0}^{\infty} a_k x^{k-\frac{5}{2}}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{3}{2}}\right), a_{k+2} = -\frac{(2k-6)a_k}{2k+4}, a_1 = 0, b_{k+2} = -\frac{(2k+2)b_k}{2k+12}, b_1 = 0\right]$

2.1.192 Problem 194

Internal problem ID [9364]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 194
Date solved : `Monday, January 27, 2025 at 06:01:56 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$y'' - \frac{2(t+1)\, y'}{t^2+2t-1} + \frac{2y}{t^2+2t-1} = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.270 (sec)

Writing the ode as

$$y'' + \frac{(-2t-2)\, y'}{t^2+2t-1} + \frac{2y}{t^2+2t-1} = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= \frac{-2t-2}{t^2+2t-1} \\ C &= \frac{2}{t^2+2t-1} \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(t) = y e^{\int \frac{B}{2A}\, dt}$$

Then (2) becomes

$$z''(t) = r z(t) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{6}{\left(t^2+2t-1\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 6 \\ t &= \left(t^2+2t-1\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(t) = \left(\frac{6}{\left(t^2+2t-1\right)^2}\right) z(t) \tag{7}$$

Equation (7) is now solved. After finding $z(t)$ then y is found using the inverse transformation

$$y = z(t)\, e^{-\int \frac{B}{2A}\, dt}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.368: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 0 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = \left(t^2+2t-1\right)^2$. There is a pole at $t = \sqrt{2}-1$ of order 2. There is a pole at $t = -1-\sqrt{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{3}{4\left(t-\sqrt{2}+1\right)^2} + \frac{3}{4\left(t+1+\sqrt{2}\right)^2} - \frac{3\sqrt{2}}{8\left(t-\sqrt{2}+1\right)} + \frac{3\sqrt{2}}{8\left(t+1+\sqrt{2}\right)}$$

For the pole at $t = \sqrt{2}-1$ let b be the coefficient of $\frac{1}{\left(t-\sqrt{2}+1\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

For the pole at $t=-1-\sqrt{2}$ let b be the coefficient of $\frac{1}{\left(t+1+\sqrt{2}\right)^{2}}$ in the partial fractions decomposition of r given above. Therefore $b=\frac{3}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^{+} &= \frac{1}{2}+\sqrt{1+4b}=\frac{3}{2} \\
\alpha_c^{-} &= \frac{1}{2}-\sqrt{1+4b}=-\frac{1}{2}
\end{aligned}
$$

Since the order of r at ∞ is $4>2$ then

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= 0 \\
\alpha_\infty^{-} &= 1
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r=\frac{6}{\left(t^{2}+2t-1\right)^{2}}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
$\sqrt{2}-1$	2	0	$\frac{3}{2}$	$-\frac{1}{2}$
$-1-\sqrt{2}$	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-}=1$ then

$$
\begin{aligned}
d &= \alpha_\infty^{-}-\left(\alpha_{c_1}^{-}+\alpha_{c_2}^{+}\right) \\
&= 1-(1) \\
&= 0
\end{aligned}
$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$
\omega=\sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c+\frac{\alpha_c^{s(c)}}{t-c}\right)+s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1}+\frac{\alpha_{c_1}^{-}}{t-c_1}\right)+\left((+)[\sqrt{r}]_{c_2}+\frac{\alpha_{c_2}^{+}}{t-c_2}\right)+(-)[\sqrt{r}]_\infty \\
&= -\frac{1}{2\left(t-\sqrt{2}+1\right)}+\frac{3}{2\left(t+1+\sqrt{2}\right)}+(-)\,(0) \\
&= -\frac{1}{2\left(t-\sqrt{2}+1\right)}+\frac{3}{2\left(t+1+\sqrt{2}\right)} \\
&= \frac{t+1-2\sqrt{2}}{t^{2}+2t-1}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(t)$ of degree $d = 0$ to solve the ode. The polynomial $p(t)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\,p = 0 \tag{1A}$$

Let

$$p(t) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{2\left(t-\sqrt{2}+1\right)} + \frac{3}{2\left(t+1+\sqrt{2}\right)}\right)(0) + \left(\left(\frac{1}{2\left(t-\sqrt{2}+1\right)^2} - \frac{3}{2\left(t+1+\sqrt{2}\right)^2}\right) + \left(-\frac{}{2\,(t -}\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(t) &= p e^{\int \omega \, dt} \\
&= \mathrm{e}^{\int \left(-\frac{1}{2\left(t-\sqrt{2}+1\right)} + \frac{3}{2\left(t+1+\sqrt{2}\right)}\right) dt} \\
&= \frac{\left(t+1+\sqrt{2}\right)^{3/2}}{\sqrt{t-\sqrt{2}+1}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dt} \\
&= z_1 e^{-\int \frac{1}{2}\frac{\frac{-2t-2}{t^2+2t-1}}{1}\, dt} \\
&= z_1 e^{\frac{\ln\left(t^2+2t-1\right)}{2}} \\
&= z_1\left(\sqrt{t^2+2t-1}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{\sqrt{t^2+2t-1}\,\left(t+1+\sqrt{2}\right)^{3/2}}{\sqrt{t-\sqrt{2}+1}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dt}}{y_1^2}\, dt$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{\frac{-2t-2}{t^2+2t-1}}{1}\, dt}}{(y_1)^2}\, dt \\
&= y_1 \int \frac{e^{\ln\left(t^2+2t-1\right)}}{(y_1)^2}\, dt \\
&= y_1\left(\frac{\sqrt{2}}{\left(t+1+\sqrt{2}\right)^2} - \frac{1}{t+1+\sqrt{2}}\right)
\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{\sqrt{t^2+2t-1}\,\left(t+1+\sqrt{2}\right)^{3/2}}{\sqrt{t-\sqrt{2}+1}}\right) \\
&\quad + c_2 \left(\frac{\sqrt{t^2+2t-1}\,\left(t+1+\sqrt{2}\right)^{3/2}}{\sqrt{t-\sqrt{2}+1}} \left(\frac{\sqrt{2}}{\left(t+1+\sqrt{2}\right)^2} - \frac{1}{t+1+\sqrt{2}}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$\frac{d^2}{dt^2}y(t) - \frac{2(t+1)\left(\frac{d}{dt}y(t)\right)}{t^2+2t-1} + \frac{2y(t)}{t^2+2t-1} = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dt^2}y(t)$

- □ Check to see if t_0 is a regular singular point
  - ◦ Define functions

    $\left[P_2(t) = -\frac{2(t+1)}{t^2+2t-1}, P_3(t) = \frac{2}{t^2+2t-1}\right]$
  - ◦ $\left(t+\sqrt{2}+1\right) \cdot P_2(t)$ is analytic at $t = -\sqrt{2}-1$

    $\left(\left(t+\sqrt{2}+1\right) \cdot P_2(t)\right)\Big|_{t=-\sqrt{2}-1} = 0$
  - ◦ $\left(t+\sqrt{2}+1\right)^2 \cdot P_3(t)$ is analytic at $t = -\sqrt{2}-1$

    $\left(\left(t+\sqrt{2}+1\right)^2 \cdot P_3(t)\right)\Big|_{t=-\sqrt{2}-1} = 0$
  - ◦ $t = -\sqrt{2}-1$is a regular singular point

    Check to see if t_0 is a regular singular point

    $t_0 = -\sqrt{2}-1$
- Multiply by denominators

  $(t^2+2t-1)\left(\frac{d^2}{dt^2}y(t)\right) + (-2t-2)\left(\frac{d}{dt}y(t)\right) + 2y(t) = 0$
- Change variables using $t = u-\sqrt{2}-1$ so that the regular singular point is at $u = 0$

  $\left(u^2-2u\sqrt{2}\right)\left(\frac{d^2}{du^2}y(u)\right) + \left(-2u+2\sqrt{2}\right)\left(\frac{d}{du}y(u)\right) + 2y(u) = 0$
- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$
- □ Rewrite ODE with series expansions
  - ◦ Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..1$

    $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,u^{k+r-1+m}$
  - ◦ Shift index using $k- >k+1-m$

    $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,u^{k+r}$

CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$y'' - 4ty' + (4t^2 - 2)\, y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.056 (sec)

Writing the ode as

$$y'' - 4ty' + (4t^2 - 2)\, y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -4t \\ C &= 4t^2 - 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(t) = y e^{\int \frac{B}{2A}\, dt}$$

Then (2) becomes

$$z''(t) = r z(t) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(t) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(t)$ then y is found using the inverse transformation

$$y = z(t)\, e^{-\int \frac{B}{2A}\, dt}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.370: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of t, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(t) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dt} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-4t}{1}\, dt} \\ &= z_1 e^{t^2} \\ &= z_1 \left(\mathrm{e}^{t^2}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{t^2}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dt}}{y_1^2}\, dt$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-4t}{1}\, dt}}{(y_1)^2}\, dt \\
&= y_1 \int \frac{e^{2t^2}}{(y_1)^2}\, dt \\
&= y_1(t)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(e^{t^2}\right) + c_2\left(e^{t^2}(t)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve
$\frac{d^2}{dt^2}y(t) - 4t\left(\frac{d}{dt}y(t)\right) + (4t^2 - 2)\, y(t) = 0$

- Highest derivative means the order of the ODE is 2
  $\frac{d^2}{dt^2}y(t)$
- Assume series solution for $y(t)$
  $y(t) = \sum_{k=0}^{\infty} a_k t^k$
- □ Rewrite ODE with series expansions
  - Convert $t^m \cdot y(t)$ to series expansion for $m = 0..2$
    $t^m \cdot y(t) = \sum_{k=\max(0,-m)}^{\infty} a_k t^{k+m}$
  - Shift index using $k- >k - m$
    $t^m \cdot y(t) = \sum_{k=\max(0,-m)+m}^{\infty} a_{k-m} t^k$
  - Convert $t \cdot \left(\frac{d}{dt}y(t)\right)$ to series expansion
    $t \cdot \left(\frac{d}{dt}y(t)\right) = \sum_{k=0}^{\infty} a_k k\, t^k$
  - Convert $\frac{d^2}{dt^2}y(t)$ to series expansion
    $\frac{d^2}{dt^2}y(t) = \sum_{k=2}^{\infty} a_k k(k-1)\, t^{k-2}$
  - Shift index using $k- >k + 2$
    $\frac{d^2}{dt^2}y(t) = \sum_{k=0}^{\infty} a_{k+2}(k+2)(k+1)\, t^k$

  Rewrite ODE with series expansions
  $2a_2 - 2a_0 + (6a_3 - 6a_1)\, t + \left(\sum_{k=2}^{\infty} \left(a_{k+2}(k+2)(k+1) - 2a_k(2k+1) + 4a_{k-2}\right) t^k\right) = 0$
- The coefficients of each power of t must be 0
  $[2a_2 - 2a_0 = 0, 6a_3 - 6a_1 = 0]$
- Solve for the dependent coefficient(s)
  $\{a_2 = a_0, a_3 = a_1\}$
- Each term in the series must be 0, giving the recursion relation
  $(k^2 + 3k + 2)\, a_{k+2} - 4a_k k - 2a_k + 4a_{k-2} = 0$

- Shift index using $k->k+2$
  $$\left((k+2)^2+3k+8\right)a_{k+4}-4a_{k+2}(k+2)-2a_{k+2}+4a_k=0$$
- Recursion relation that defines the series solution to the ODE
  $$\left[y(t)=\sum_{k=0}^{\infty}a_k t^k, a_{k+4}=\frac{2(2ka_{k+2}-2a_k+5a_{k+2})}{k^2+7k+12}, a_2=a_0, a_3=a_1\right]$$

2.1.194 Problem 196

Internal problem ID [9366]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 196
Date solved : `Monday, January 27, 2025 at 06:01:57 PM`
CAS classification : `[_Gegenbauer]`

Solve

$$\left(-t^2+1\right)y''-2ty'+2y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.236 (sec)

Writing the ode as

$$\left(-t^2+1\right)y''-2ty'+2y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=-t^2+1\\B&=-2t\\C&=2\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(t)=ye^{\int \frac{B}{2A}\,dt}$$

Then (2) becomes

$$z''(t)=rz(t) \tag{4}$$

Where r is given by

$$\begin{aligned}r&=\frac{s}{t}\\&=\frac{2AB'-2BA'+B^2-4AC}{4A^2}\end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{2t^2-3}{\left(t^2-1\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned}s&=2t^2-3\\t&=\left(t^2-1\right)^2\end{aligned}$$

Therefore eq. (4) becomes

$$z''(t)=\left(\frac{2t^2-3}{\left(t^2-1\right)^2}\right)z(t) \tag{7}$$

Equation (7) is now solved. After finding $z(t)$ then y is found using the inverse transformation

$$y = z(t)\, e^{-\int \frac{B}{2A}\, dt}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.372: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 4 - 2 \\
&= 2
\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (t^2-1)^2$. There is a pole at $t = 1$ of order 2. There is a pole at $t = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{5}{4(t-1)} - \frac{1}{4(t+1)^2} - \frac{5}{4(t+1)} - \frac{1}{4(t-1)^2}$$

For the pole at $t = 1$ let b be the coefficient of $\frac{1}{(t-1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}
\end{aligned}$$

For the pole at $t = -1$ let b be the coefficient of $\frac{1}{(t+1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}
\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{t^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{2t^2 - 3}{(t^2 - 1)^2}$$

Since the $\gcd(s, t) = 1$. This gives $b = 2$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1 + 4b} = 2 \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1 + 4b} = -1
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{2t^2 - 3}{(t^2 - 1)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
1	2	0	$\frac{1}{2}$	$\frac{1}{2}$
-1	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	2	-1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = 2$ then

$$\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^- + \alpha_{c_2}^-\right) \\
&= 2 - (1) \\
&= 1
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{t - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{t - c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{t - c_2} \right) + (+)[\sqrt{r}]_\infty \\
&= \frac{1}{2t - 2} + \frac{1}{2t + 2} + (0) \\
&= \frac{1}{2t - 2} + \frac{1}{2t + 2} \\
&= \frac{t}{t^2 - 1}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(t)$ of degree $d = 1$ to solve the ode. The polynomial $p(t)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(t) = t + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{2t-2} + \frac{1}{2t+2}\right)(1) + \left(\left(-\frac{1}{2(t-1)^2} - \frac{1}{2(t+1)^2}\right) + \left(\frac{1}{2t-2} + \frac{1}{2t+2}\right)^2 - \left(\frac{2t^2-3}{(t^2-1)^2}\right)\right) = 0$$

$$-\frac{2a_0}{t^2-1} = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 0\}$$

Substituting these coefficients in $p(t)$ in eq. (2A) results in

$$p(t) = t$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(t) &= p e^{\int \omega \, dt} \\ &= (t)\, e^{\int \left(\frac{1}{2t-2} + \frac{1}{2t+2}\right) dt} \\ &= (t)\sqrt{(t-1)(t+1)} \\ &= t\sqrt{t^2-1} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dt} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-2t}{-t^2+1} \, dt} \\ &= z_1 e^{-\frac{\ln(t-1)}{2} - \frac{\ln(t+1)}{2}} \\ &= z_1 \left(\frac{1}{\sqrt{t-1}\,\sqrt{t+1}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{t\sqrt{t^2-1}}{\sqrt{t-1}\,\sqrt{t+1}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dt}}{y_1^2} \, dt$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-2t}{-t^2+1} \, dt}}{(y_1)^2} \, dt \\ &= y_1 \int \frac{e^{-\ln(t-1) - \ln(t+1)}}{(y_1)^2} \, dt \\ &= y_1 \left(-\frac{\ln(t+1)}{2} + \frac{\ln(t-1)}{2} + \frac{1}{t}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\frac{t\sqrt{t^2-1}}{\sqrt{t-1}\,\sqrt{t+1}}\right) + c_2 \left(\frac{t\sqrt{t^2-1}}{\sqrt{t-1}\,\sqrt{t+1}} \left(-\frac{\ln(t+1)}{2} + \frac{\ln(t-1)}{2} + \frac{1}{t}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$(-t^2+1)\left(\frac{d^2}{dt^2}y(t)\right)-2t\left(\frac{d}{dt}y(t)\right)+2y(t)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dt^2}y(t)$

- Isolate 2nd derivative

  $\frac{d^2}{dt^2}y(t)=\frac{2y(t)}{t^2-1}-\frac{2\left(\frac{d}{dt}y(t)\right)t}{t^2-1}$

- Group terms with $y(t)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dt^2}y(t)+\frac{2\left(\frac{d}{dt}y(t)\right)t}{t^2-1}-\frac{2y(t)}{t^2-1}=0$

□ Check to see if t_0 is a regular singular point

  - Define functions

    $\left[P_2(t)=\frac{2t}{t^2-1}, P_3(t)=-\frac{2}{t^2-1}\right]$

  - $(t+1)\cdot P_2(t)$ is analytic at $t=-1$

    $\left((t+1)\cdot P_2(t)\right)\bigg|_{t=-1}=1$

  - $(t+1)^2\cdot P_3(t)$ is analytic at $t=-1$

    $\left((t+1)^2\cdot P_3(t)\right)\bigg|_{t=-1}=0$

  - $t=-1$is a regular singular point

  Check to see if t_0 is a regular singular point

  $t_0=-1$

- Multiply by denominators

  $(t^2-1)\left(\frac{d^2}{dt^2}y(t)\right)+2t\left(\frac{d}{dt}y(t)\right)-2y(t)=0$

- Change variables using $t=u-1$ so that the regular singular point is at $u=0$

  $(u^2-2u)\left(\frac{d^2}{du^2}y(u)\right)+(2u-2)\left(\frac{d}{du}y(u)\right)-2y(u)=0$

- Assume series solution for $y(u)$

  $y(u)=\sum_{k=0}^{\infty} a_k u^{k+r}$

□ Rewrite ODE with series expansions

  - Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$

    $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty} a_k(k+r)\,u^{k+r-1+m}$

  - Shift index using $k->k+1-m$

    $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,u^{k+r}$

  - Convert $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m=1..2$

    $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\,u^{k+r-2+m}$

  - Shift index using $k->k+2-m$

    $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\,u^{k+r}$

  Rewrite ODE with series expansions

  $-2a_0r^2u^{-1+r}+\left(\sum_{k=0}^{\infty}\left(-2a_{k+1}(k+1+r)^2+a_k(k+r+2)(k+r-1)\right)u^{k+r}\right)=0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$-2r^2 = 0$

- Values of r that satisfy the indicial equation
  $r = 0$
- Each term in the series must be 0, giving the recursion relation
  $-2a_{k+1}(k+1)^2 + a_k(k+2)(k-1) = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+1} = \frac{a_k(k+2)(k-1)}{2(k+1)^2}$
- Recursion relation for $r = 0$; series terminates at $k = 1$
  $a_{k+1} = \frac{a_k(k+2)(k-1)}{2(k+1)^2}$
- Apply recursion relation for $k = 0$
  $a_1 = -a_0$
- Terminating series solution of the ODE for $r = 0$. Use reduction of order to find the second linea
  $y(u) = a_0 \cdot (-u+1)$
- Revert the change of variables $u = t+1$
  $[y(t) = -a_0 t]$

2.1.195 Problem 197

Internal problem ID [9367]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 197
Date solved : `Monday, January 27, 2025 at 06:01:58 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$\left(t^{2}+1\right) y''-2 t y'+2 y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.258 (sec)

Writing the ode as

$$\left(t^{2}+1\right) y''-2 t y'+2 y=0 \tag{1}$$

$$A y''+B y'+C y=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= t^{2}+1 \\ B &= -2 t \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(t)=y e^{\int \frac{B}{2 A} d t}$$

Then (2) becomes

$$z''(t)=r z(t) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2 A B'-2 B A'+B^{2}-4 A C}{4 A^{2}} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r=\frac{-3}{\left(t^{2}+1\right)^{2}} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -3 \\ t &= \left(t^{2}+1\right)^{2} \end{aligned}$$

Therefore eq. (4) becomes

$$z''(t)=\left(-\frac{3}{\left(t^{2}+1\right)^{2}}\right) z(t) \tag{7}$$

Equation (7) is now solved. After finding $z(t)$ then y is found using the inverse transformation

$$y = z(t)\, e^{-\int \frac{B}{2A}\, dt}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.374: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 0 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (t^2+1)^2$. There is a pole at $t = i$ of order 2. There is a pole at $t = -i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{3}{4\,(t-i)^2} + \frac{3}{4\,(t+i)^2} + \frac{3i}{4\,(t-i)} - \frac{3i}{4\,(t+i)}$$

For the pole at $t = i$ let b be the coefficient of $\frac{1}{(t-i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

For the pole at $t = -i$ let b be the coefficient of $\frac{1}{(t+i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $4 > 2$ then

$$\begin{aligned}[\sqrt{r}]_\infty &= 0\\ \alpha_\infty^+ &= 0\\ \alpha_\infty^- &= 1\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = -\frac{3}{(t^2+1)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
i	2	0	$\frac{3}{2}$	$-\frac{1}{2}$
$-i$	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$ then

$$\begin{aligned}d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^+\right)\\ &= 1 - (1)\\ &= 0\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{t-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{t-c_1}\right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{t-c_2}\right) + (-)[\sqrt{r}]_\infty\\ &= -\frac{1}{2(t-i)} + \frac{3}{2(t+i)} + (-)(0)\\ &= -\frac{1}{2(t-i)} + \frac{3}{2(t+i)}\\ &= \frac{t-2i}{t^2+1}\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(t)$ of degree $d = 0$ to solve the ode. The polynomial $p(t)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\,p = 0 \tag{1A}$$

Let

$$p(t) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(-\frac{1}{2(t-i)}+\frac{3}{2(t+i)}\right)(0)+\left(\left(\frac{1}{2(t-i)^2}-\frac{3}{2(t+i)^2}\right)+\left(-\frac{1}{2(t-i)}+\frac{3}{2(t+i)}\right)^2-\left(-\frac{3}{(t^2+1}\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z''=rz$ is

$$\begin{aligned} z_1(t) &= pe^{\int \omega\,dt} \\ &= e^{\int \left(-\frac{1}{2(t-i)}+\frac{3}{2(t+i)}\right)dt} \\ &= \frac{(t^2+1)^{3/2}}{(it+1)^2} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dt} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-2t}{t^2+1}\,dt} \\ &= z_1 e^{\frac{\ln(t^2+1)}{2}} \\ &= z_1\left(\sqrt{t^2+1}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{(t^2+1)^2}{(it+1)^2}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dt}}{y_1^2}\,dt$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-2t}{t^2+1}\,dt}}{(y_1)^2}\,dt \\ &= y_1 \int \frac{e^{\ln(t^2+1)}}{(y_1)^2}\,dt \\ &= y_1\left(-\frac{t}{(t+i)^2}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\frac{(t^2+1)^2}{(it+1)^2}\right) + c_2\left(\frac{(t^2+1)^2}{(it+1)^2}\left(-\frac{t}{(t+i)^2}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

2.1.196 Problem 198

Internal problem ID [9368]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 198
Date solved : `Monday, January 27, 2025 at 06:01:59 PM`
CAS classification : `[_Gegenbauer]`

Solve

$$\left(-t^2+1\right) y''-2ty'+6y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.267 (sec)

Writing the ode as

$$\left(-t^2+1\right) y''-2ty'+6y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= -t^2+1 \\ B &= -2t \\ C &= 6 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(t)=ye^{\int \frac{B}{2A}\,dt}$$

Then (2) becomes

$$z''(t)=rz(t) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{6t^2-7}{\left(t^2-1\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 6t^2-7 \\ t &= \left(t^2-1\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(t)=\left(\frac{6t^2-7}{\left(t^2-1\right)^2}\right) z(t) \tag{7}$$

Equation (7) is now solved. After finding $z(t)$ then y is found using the inverse transformation

$$y = z(t)\, e^{-\int \frac{B}{2A}\, dt}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.375: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (t^2 - 1)^2$. There is a pole at $t = 1$ of order 2. There is a pole at $t = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{13}{4\,(t-1)} - \frac{13}{4\,(t+1)} - \frac{1}{4\,(t-1)^2} - \frac{1}{4\,(t+1)^2}$$

For the pole at $t = 1$ let b be the coefficient of $\frac{1}{(t-1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

For the pole at $t = -1$ let b be the coefficient of $\frac{1}{(t+1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{t^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{6t^2 - 7}{(t^2 - 1)^2}$$

Since the $\gcd(s, t) = 1$. This gives $b = 6$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1 + 4b} = 3 \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1 + 4b} = -2
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{6t^2 - 7}{(t^2 - 1)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
1	2	0	$\frac{1}{2}$	$\frac{1}{2}$
-1	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	3	-2

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = 3$ then

$$\begin{aligned}
d &= \alpha_\infty^+ - (\alpha_{c_1}^- + \alpha_{c_2}^-) \\
&= 3 - (1) \\
&= 2
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{t - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{t - c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{t - c_2} \right) + (+)[\sqrt{r}]_\infty \\
&= \frac{1}{2t - 2} + \frac{1}{2t + 2} + (0) \\
&= \frac{1}{2t - 2} + \frac{1}{2t + 2} \\
&= \frac{t}{t^2 - 1}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(t)$ of degree $d = 2$ to solve the ode. The polynomial $p(t)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(t) = t^2 + a_1 t + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(2) + 2\left(\frac{1}{2t-2} + \frac{1}{2t+2}\right)(2t + a_1) + \left(\left(-\frac{1}{2(t-1)^2} - \frac{1}{2(t+1)^2}\right) + \left(\frac{1}{2t-2} + \frac{1}{2t+2}\right)^2 - \left(\frac{6t^2-7}{(t^2-1)^2}\right.\right.$$

$$\frac{-4a_1 t - 6a_0 - 2}{t^2 - 1}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\left\{a_0 = -\frac{1}{3}, a_1 = 0\right\}$$

Substituting these coefficients in $p(t)$ in eq. (2A) results in

$$p(t) = t^2 - \frac{1}{3}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(t) &= p e^{\int \omega \, dt} \\ &= \left(t^2 - \frac{1}{3}\right) e^{\int \left(\frac{1}{2t-2} + \frac{1}{2t+2}\right) dt} \\ &= \left(t^2 - \frac{1}{3}\right) \sqrt{(t-1)(t+1)} \\ &= \frac{(3t^2 - 1)\sqrt{t^2 - 1}}{3} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dt} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-2t}{-t^2+1} \, dt} \\ &= z_1 e^{-\frac{\ln(t-1)}{2} - \frac{\ln(t+1)}{2}} \\ &= z_1 \left(\frac{1}{\sqrt{t-1}\sqrt{t+1}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{(3t^2 - 1)\sqrt{t^2 - 1}}{3\sqrt{t-1}\sqrt{t+1}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dt}}{y_1^2} \, dt$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-2t}{-t^2+1} \, dt}}{(y_1)^2} \, dt \\ &= y_1 \int \frac{e^{-\ln(t-1) - \ln(t+1)}}{(y_1)^2} \, dt \\ &= y_1 \left(\frac{9\ln(t-1)}{8} - \frac{9\ln(t+1)}{8} + \frac{9t}{4\left(t^2 - \frac{1}{3}\right)}\right) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{(3t^2-1)\sqrt{t^2-1}}{3\sqrt{t-1}\,\sqrt{t+1}}\right) + c_2\left(\frac{(3t^2-1)\sqrt{t^2-1}}{3\sqrt{t-1}\,\sqrt{t+1}}\left(\frac{9\ln(t-1)}{8} - \frac{9\ln(t+1)}{8} + \frac{9t}{4\left(t^2-\frac{1}{3}\right)}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve
$(-t^2+1)\left(\frac{d^2}{dt^2}y(t)\right) - 2t\left(\frac{d}{dt}y(t)\right) + 6y(t) = 0$

- Highest derivative means the order of the ODE is 2
  $\frac{d^2}{dt^2}y(t)$
- Isolate 2nd derivative
  $\frac{d^2}{dt^2}y(t) = \frac{6y(t)}{t^2-1} - \frac{2\left(\frac{d}{dt}y(t)\right)t}{t^2-1}$
- Group terms with $y(t)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear
  $\frac{d^2}{dt^2}y(t) + \frac{2\left(\frac{d}{dt}y(t)\right)t}{t^2-1} - \frac{6y(t)}{t^2-1} = 0$

☐ Check to see if t_0 is a regular singular point
  - Define functions
    $\left[P_2(t) = \frac{2t}{t^2-1}, P_3(t) = -\frac{6}{t^2-1}\right]$
  - $(t+1)\cdot P_2(t)$ is analytic at $t=-1$
    $\left((t+1)\cdot P_2(t)\right)\Big|_{t=-1} = 1$
  - $(t+1)^2\cdot P_3(t)$ is analytic at $t=-1$
    $\left((t+1)^2\cdot P_3(t)\right)\Big|_{t=-1} = 0$
  - $t=-1$is a regular singular point
    Check to see if t_0 is a regular singular point
    $t_0 = -1$
- Multiply by denominators
  $(t^2-1)\left(\frac{d^2}{dt^2}y(t)\right) + 2t\left(\frac{d}{dt}y(t)\right) - 6y(t) = 0$
- Change variables using $t = u-1$ so that the regular singular point is at $u=0$
  $(u^2-2u)\left(\frac{d^2}{du^2}y(u)\right) + (2u-2)\left(\frac{d}{du}y(u)\right) - 6y(u) = 0$
- Assume series solution for $y(u)$
  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

☐ Rewrite ODE with series expansions
  - Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..1$
    $u^m\cdot\left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,u^{k+r-1+m}$
  - Shift index using $k->k+1-m$
    $u^m\cdot\left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,u^{k+r}$
  - Convert $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m = 1..2$

$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\,u^{k+r-2+m}$

- Shift index using $k->k+2-m$

  $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\,u^{k+r}$

  Rewrite ODE with series expansions

  $-2a_0r^2u^{-1+r} + \left(\sum_{k=0}^{\infty}\left(-2a_{k+1}(k+1+r)^2 + a_k(k+r+3)(k+r-2)\right)u^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $-2r^2 = 0$
- Values of r that satisfy the indicial equation
  $r = 0$
- Each term in the series must be 0, giving the recursion relation
  $-2a_{k+1}(k+1)^2 + a_k(k+3)(k-2) = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+1} = \frac{a_k(k+3)(k-2)}{2(k+1)^2}$
- Recursion relation for $r = 0$; series terminates at $k = 2$
  $a_{k+1} = \frac{a_k(k+3)(k-2)}{2(k+1)^2}$
- Apply recursion relation for $k = 0$
  $a_1 = -3a_0$
- Apply recursion relation for $k = 1$
  $a_2 = -\frac{a_1}{2}$
- Express in terms of a_0
  $a_2 = \frac{3a_0}{2}$
- Terminating series solution of the ODE for $r = 0$. Use reduction of order to find the second li
  $y(u) = a_0 \cdot \left(1 - 3u + \frac{3}{2}u^2\right)$
- Revert the change of variables $u = t + 1$
  $\left[y(t) = a_0\left(\frac{3t^2}{2} - \frac{1}{2}\right)\right]$

2.1.197 Problem 199

Internal problem ID [9369]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 199
Date solved : `Monday, January 27, 2025 at 06:01:59 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$(2t+1)\,y''-4(t+1)\,y'+4y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.230 (sec)

Writing the ode as

$$(2t+1)\,y''+(-4t-4)\,y'+4y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2t+1\\ B &= -4t-4 \\ C &= 4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(t)=y e^{\int \frac{B}{2A}\,dt}$$

Then (2) becomes

$$z''(t)=rz(t) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{4t^2+2}{\left(2t+1\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 4t^2+2 \\ t &= \left(2t+1\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(t)=\left(\frac{4t^2+2}{\left(2t+1\right)^2}\right)z(t) \tag{7}$$

Equation (7) is now solved. After finding $z(t)$ then y is found using the inverse transformation

$$y = z(t)\, e^{-\int \frac{B}{2A}\, dt}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.377: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (2t+1)^2$. There is a pole at $t = -\frac{1}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1,2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = 1 + \frac{3}{4\left(t+\frac{1}{2}\right)^2} - \frac{1}{t+\frac{1}{2}}$$

For the pole at $t = -\frac{1}{2}$ let b be the coefficient of $\frac{1}{\left(t+\frac{1}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving t^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i t^i \\ &= \sum_{i=0}^{0} a_i t^i \end{aligned} \tag{8}$$

Let a be the coefficient of $t^v = t^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx 1 - \frac{1}{2t} + \frac{1}{2t^2} - \frac{1}{4t^3} + \frac{3}{32t^4} - \frac{3}{64t^5} + \frac{1}{32t^6} - \frac{1}{64t^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = 1$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i t^i \\ &= 1 \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $t^{v-1} = t^{-1} = \frac{1}{t}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = 1$$

This shows that the coefficient of $\frac{1}{t}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{t}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{t}$ in r will be the coefficient in R of the term in t of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{4t^2+2}{4t^2+4t+1} \\ &= Q + \frac{R}{4t^2+4t+1} \\ &= (1) + \left(\frac{-4t+1}{4t^2+4t+1}\right) \\ &= 1 + \frac{-4t+1}{4t^2+4t+1} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term t in the remainder R is -4. Dividing this by leading coefficient in t which is 4 gives -1. Now b can be found.

$$\begin{aligned} b &= (-1) - (0) \\ &= -1 \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= 1 \\ \alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-1}{1} - 0\right) &&= -\frac{1}{2} \\ \alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-1}{1} - 0\right) &&= \frac{1}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{4t^2+2}{(2t+1)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
$-\frac{1}{2}$	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	1	$-\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = -\frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^+ - (\alpha_{c_1}^-) \\ &= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{t-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{t-c_1} \right) + (+)[\sqrt{r}]_\infty \\ &= -\frac{1}{2\left(t+\frac{1}{2}\right)} + (1) \\ &= -\frac{1}{2\left(t+\frac{1}{2}\right)} + 1 \\ &= \frac{2t}{2t+1} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(t)$ of degree $d = 0$ to solve the ode. The polynomial $p(t)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(t) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{2\left(t+\frac{1}{2}\right)} + 1\right)(0) + \left(\left(\frac{1}{2\left(t+\frac{1}{2}\right)^2}\right) + \left(-\frac{1}{2\left(t+\frac{1}{2}\right)} + 1\right)^2 - \left(\frac{4t^2+2}{(2t+1)^2}\right) \right) = 0$$

$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(t) &= p e^{\int \omega \, dt} \\
&= \mathrm{e}^{\int \left(-\frac{1}{2\left(t+\frac{1}{2}\right)}+1\right) dt} \\
&= \frac{\mathrm{e}^{t}}{\sqrt{2t+1}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dt} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-4t-4}{2t+1} \, dt} \\
&= z_1 e^{t+\frac{\ln(2t+1)}{2}} \\
&= z_1 \left(\sqrt{2t+1}\, \mathrm{e}^{t}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{2t}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dt}}{y_1^2} \, dt
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-4t-4}{2t+1} \, dt}}{(y_1)^2} \, dt \\
&= y_1 \int \frac{e^{2t+\ln(2t+1)}}{(y_1)^2} \, dt \\
&= y_1 \left(-\frac{(t+1)\,\mathrm{e}^{2t+\ln(2t+1)}\mathrm{e}^{-4t}}{2t+1}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{2t}\right) + c_2 \left(\mathrm{e}^{2t} \left(-\frac{(t+1)\,\mathrm{e}^{2t+\ln(2t+1)}\mathrm{e}^{-4t}}{2t+1}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$(2t+1)\left(\frac{d^2}{dt^2}y(t)\right)-4(t+1)\left(\frac{d}{dt}y(t)\right)+4y(t)=0$

- Highest derivative means the order of the ODE is 2

$\frac{d^2}{dt^2}y(t)$

- Isolate 2nd derivative

$\frac{d^2}{dt^2}y(t)=-\frac{4y(t)}{2t+1}+\frac{4(t+1)\left(\frac{d}{dt}y(t)\right)}{2t+1}$

- Group terms with $y(t)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$\frac{d^2}{dt^2}y(t)-\frac{4(t+1)\left(\frac{d}{dt}y(t)\right)}{2t+1}+\frac{4y(t)}{2t+1}=0$

□ Check to see if $t_0=-\frac{1}{2}$ is a regular singular point

  ◦ Define functions

  $\left[P_2(t)=-\frac{4(t+1)}{2t+1}, P_3(t)=\frac{4}{2t+1}\right]$

  ◦ $\left(t+\frac{1}{2}\right)\cdot P_2(t)$ is analytic at $t=-\frac{1}{2}$

  $\left(\left(t+\frac{1}{2}\right)\cdot P_2(t)\right)\bigg|_{t=-\frac{1}{2}}=-1$

  ◦ $\left(t+\frac{1}{2}\right)^2\cdot P_3(t)$ is analytic at $t=-\frac{1}{2}$

  $\left(\left(t+\frac{1}{2}\right)^2\cdot P_3(t)\right)\bigg|_{t=-\frac{1}{2}}=0$

  ◦ $t=-\frac{1}{2}$is a regular singular point

Check to see if $t_0=-\frac{1}{2}$ is a regular singular point

$t_0=-\frac{1}{2}$

- Multiply by denominators

$(2t+1)\left(\frac{d^2}{dt^2}y(t)\right)+(-4t-4)\left(\frac{d}{dt}y(t)\right)+4y(t)=0$

- Change variables using $t=u-\frac{1}{2}$ so that the regular singular point is at $u=0$

$2u\left(\frac{d^2}{du^2}y(u)\right)+(-4u-2)\left(\frac{d}{du}y(u)\right)+4y(u)=0$

- Assume series solution for $y(u)$

$y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$

  $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,u^{k+r-1+m}$

  ◦ Shift index using $k->k+1-m$

  $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,u^{k+r}$

  ◦ Convert $u\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion

  $u\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)(k+r-1)\,u^{k+r-1}$

  ◦ Shift index using $k->k+1$

  $u\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=-1}^{\infty}a_{k+1}(k+1+r)(k+r)\,u^{k+r}$

Rewrite ODE with series expansions

$2a_0r(-2+r)\,u^{-1+r}+\left(\sum_{k=0}^{\infty}(2a_{k+1}(k+1+r)(k+r-1)-4a_k(k+r-1))\,u^{k+r}\right)=0$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $2r(-2+r) = 0$
- Values of r that satisfy the indicial equation
  $r \in \{0, 2\}$
- Each term in the series must be 0, giving the recursion relation
  $2(a_{k+1}(k+1+r) - 2a_k)(k+r-1) = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+1} = \frac{2a_k}{k+1+r}$
- Recursion relation for $r = 0$
  $a_{k+1} = \frac{2a_k}{k+1}$
- Solution for $r = 0$
  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+1} = \frac{2a_k}{k+1}\right]$
- Revert the change of variables $u = t + \frac{1}{2}$
  $\left[y(t) = \sum_{k=0}^{\infty} a_k \left(t+\frac{1}{2}\right)^k, a_{k+1} = \frac{2a_k}{k+1}\right]$
- Recursion relation for $r = 2$
  $a_{k+1} = \frac{2a_k}{k+3}$
- Solution for $r = 2$
  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+2}, a_{k+1} = \frac{2a_k}{k+3}\right]$
- Revert the change of variables $u = t + \frac{1}{2}$
  $\left[y(t) = \sum_{k=0}^{\infty} a_k \left(t+\frac{1}{2}\right)^{k+2}, a_{k+1} = \frac{2a_k}{k+3}\right]$
- Combine solutions and rename parameters
  $\left[y(t) = \left(\sum_{k=0}^{\infty} a_k \left(t+\frac{1}{2}\right)^k\right) + \left(\sum_{k=0}^{\infty} b_k \left(t+\frac{1}{2}\right)^{k+2}\right), a_{k+1} = \frac{2a_k}{k+1}, b_{k+1} = \frac{2b_k}{k+3}\right]$

CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$t^2y'' + ty' + \left(t^2 - \frac{1}{4}\right) y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.136 (sec)

Writing the ode as

$$t^2y'' + ty' + \left(t^2 - \frac{1}{4}\right) y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= t^2 \\ B &= t \\ C &= t^2 - \frac{1}{4} \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(t) = ye^{\int \frac{B}{2A}\, dt}$$

Then (2) becomes

$$z''(t) = rz(t) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(t) = -z(t) \tag{7}$$

Equation (7) is now solved. After finding $z(t)$ then y is found using the inverse transformation

$$y = z(t)\, e^{-\int \frac{B}{2A}\, dt}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.379: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of t, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(t) = \cos(t)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dt} \\ &= z_1 e^{-\int \frac{1}{2}\frac{t}{t^2}\, dt} \\ &= z_1 e^{-\frac{\ln(t)}{2}} \\ &= z_1 \left(\frac{1}{\sqrt{t}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{\cos(t)}{\sqrt{t}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dt}}{y_1^2}\, dt$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{t}{t^2}\, dt}}{(y_1)^2}\, dt \\ &= y_1 \int \frac{e^{-\ln(t)}}{(y_1)^2}\, dt \\ &= y_1(\tan(t)) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\frac{\cos(t)}{\sqrt{t}}\right) + c_2\left(\frac{\cos(t)}{\sqrt{t}}(\tan(t))\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve
$\left(\frac{d^2}{dt^2}y(t)\right)t^2 + t\left(\frac{d}{dt}y(t)\right) + \left(t^2 - \frac{1}{4}\right)y(t) = 0$

- Highest derivative means the order of the ODE is 2
  $\frac{d^2}{dt^2}y(t)$
- Isolate 2nd derivative
  $\frac{d^2}{dt^2}y(t) = -\frac{(4t^2-1)y(t)}{4t^2} - \frac{\frac{d}{dt}y(t)}{t}$
- Group terms with $y(t)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin
  $\frac{d^2}{dt^2}y(t) + \frac{\frac{d}{dt}y(t)}{t} + \frac{(4t^2-1)y(t)}{4t^2} = 0$
- ☐ Check to see if $t_0 = 0$ is a regular singular point
  - Define functions
    $\left[P_2(t) = \frac{1}{t}, P_3(t) = \frac{4t^2-1}{4t^2}\right]$
  - $t \cdot P_2(t)$ is analytic at $t = 0$
    $\left.(t \cdot P_2(t))\right|_{t=0} = 1$
  - $t^2 \cdot P_3(t)$ is analytic at $t = 0$
    $\left.(t^2 \cdot P_3(t))\right|_{t=0} = -\frac{1}{4}$
  - $t = 0$is a regular singular point
    Check to see if $t_0 = 0$ is a regular singular point
    $t_0 = 0$
- Multiply by denominators
  $4\left(\frac{d^2}{dt^2}y(t)\right)t^2 + 4t\left(\frac{d}{dt}y(t)\right) + (4t^2 - 1)y(t) = 0$
- Assume series solution for $y(t)$
  $y(t) = \sum_{k=0}^{\infty} a_k t^{k+r}$
- ☐ Rewrite ODE with series expansions

- Convert $t^m \cdot y(t)$ to series expansion for $m = 0..2$

  $t^m \cdot y(t) = \sum_{k=0}^{\infty} a_k t^{k+r+m}$
- Shift index using $k- > k - m$

  $t^m \cdot y(t) = \sum_{k=m}^{\infty} a_{k-m} t^{k+r}$
- Convert $t \cdot \left(\frac{d}{dt} y(t)\right)$ to series expansion

  $t \cdot \left(\frac{d}{dt} y(t)\right) = \sum_{k=0}^{\infty} a_k (k+r)\, t^{k+r}$
- Convert $t^2 \cdot \left(\frac{d^2}{dt^2} y(t)\right)$ to series expansion

  $t^2 \cdot \left(\frac{d^2}{dt^2} y(t)\right) = \sum_{k=0}^{\infty} a_k (k+r)(k+r-1)\, t^{k+r}$

  Rewrite ODE with series expansions

  $a_0(1+2r)(-1+2r)\, t^r + a_1(3+2r)(1+2r)\, t^{1+r} + \left(\sum_{k=2}^{\infty} (a_k(2k+2r+1)(2k+2r-1) + 4a_{k-2})\, t^k\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(1+2r)(-1+2r) = 0$
- Values of r that satisfy the indicial equation

  $r \in \left\{-\frac{1}{2}, \frac{1}{2}\right\}$
- Each term must be 0

  $a_1(3+2r)(1+2r) = 0$
- Solve for the dependent coefficient(s)

  $a_1 = 0$
- Each term in the series must be 0, giving the recursion relation

  $a_k(4k^2 + 8kr + 4r^2 - 1) + 4a_{k-2} = 0$
- Shift index using $k- > k + 2$

  $a_{k+2}\left(4(k+2)^2 + 8(k+2)\, r + 4r^2 - 1\right) + 4a_k = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{4a_k}{4k^2+8kr+4r^2+16k+16r+15}$
- Recursion relation for $r = -\frac{1}{2}$

  $a_{k+2} = -\frac{4a_k}{4k^2+12k+8}$
- Solution for $r = -\frac{1}{2}$

  $\left[y(t) = \sum_{k=0}^{\infty} a_k t^{k-\frac{1}{2}}, a_{k+2} = -\frac{4a_k}{4k^2+12k+8}, a_1 = 0\right]$
- Recursion relation for $r = \frac{1}{2}$

  $a_{k+2} = -\frac{4a_k}{4k^2+20k+24}$
- Solution for $r = \frac{1}{2}$

  $\left[y(t) = \sum_{k=0}^{\infty} a_k t^{k+\frac{1}{2}}, a_{k+2} = -\frac{4a_k}{4k^2+20k+24}, a_1 = 0\right]$
- Combine solutions and rename parameters

  $\left[y(t) = \left(\sum_{k=0}^{\infty} a_k t^{k-\frac{1}{2}}\right) + \left(\sum_{k=0}^{\infty} b_k t^{k+\frac{1}{2}}\right), a_{k+2} = -\frac{4a_k}{4k^2+12k+8}, a_1 = 0, b_{k+2} = -\frac{4b_k}{4k^2+20k+24}, b_1 = 0\right]$

2.1.199 Problem 201

Internal problem ID [9371]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 201
Date solved : Monday, January 27, 2025 at 06:02:01 PM
CAS classification : [[_2nd_order, _with_linear_symmetries]]

Solve

$$y'' - \frac{2ty'}{t^2+1} + \frac{2y}{t^2+1} = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.270 (sec)

Writing the ode as

$$y'' - \frac{2ty'}{t^2+1} + \frac{2y}{t^2+1} = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -\frac{2t}{t^2+1} \\ C &= \frac{2}{t^2+1} \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(t) = ye^{\int \frac{B}{2A}\, dt}$$

Then (2) becomes

$$z''(t) = rz(t) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-3}{(t^2+1)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -3 \\ t &= (t^2+1)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(t) = \left(-\frac{3}{(t^2+1)^2}\right) z(t) \tag{7}$$

Equation (7) is now solved. After finding $z(t)$ then y is found using the inverse transformation

$$y = z(t)\, e^{-\int \frac{B}{2A}\, dt}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.381: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 0 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (t^2+1)^2$. There is a pole at $t = i$ of order 2. There is a pole at $t = -i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{3}{4(t-i)^2} + \frac{3}{4(t+i)^2} + \frac{3i}{4(t-i)} - \frac{3i}{4(t+i)}$$

For the pole at $t = i$ let b be the coefficient of $\frac{1}{(t-i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

For the pole at $t = -i$ let b be the coefficient of $\frac{1}{(t+i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}
$$

Since the order of r at ∞ is $4 > 2$ then

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= 0 \\
\alpha_\infty^- &= 1
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = -\frac{3}{(t^2+1)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
i	2	0	$\frac{3}{2}$	$-\frac{1}{2}$
$-i$	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$ then

$$
\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^+\right) \\
&= 1 - (1) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{t-c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{t-c_1} \right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{t-c_2} \right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{1}{2(t-i)} + \frac{3}{2(t+i)} + (-)(0) \\
&= -\frac{1}{2(t-i)} + \frac{3}{2(t+i)} \\
&= \frac{t-2i}{t^2+1}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(t)$ of degree $d = 0$ to solve the ode. The polynomial $p(t)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$p(t) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{2(t-i)} + \frac{3}{2(t+i)}\right)(0) + \left(\left(\frac{1}{2(t-i)^2} - \frac{3}{2(t+i)^2}\right) + \left(-\frac{1}{2(t-i)} + \frac{3}{2(t+i)}\right)^2 - \left(-\frac{}{(t^2}\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(t) &= p e^{\int \omega \, dt} \\ &= e^{\int \left(-\frac{1}{2(t-i)} + \frac{3}{2(t+i)}\right) dt} \\ &= \frac{(t^2+1)^{3/2}}{(it+1)^2} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dt} \\ &= z_1 e^{-\int \frac{1}{2} \frac{-\frac{2t}{t^2+1}}{1} \, dt} \\ &= z_1 e^{\frac{\ln(t^2+1)}{2}} \\ &= z_1 \left(\sqrt{t^2+1}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{(t^2+1)^2}{(it+1)^2}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dt}}{y_1^2} \, dt$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-\frac{2t}{t^2+1}}{1} \, dt}}{(y_1)^2} \, dt \\ &= y_1 \int \frac{e^{\ln(t^2+1)}}{(y_1)^2} \, dt \\ &= y_1 \left(-\frac{t}{(t+i)^2}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\frac{(t^2+1)^2}{(it+1)^2}\right) + c_2 \left(\frac{(t^2+1)^2}{(it+1)^2} \left(-\frac{t}{(t+i)^2}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

2.1.200 Problem 202

Internal problem ID [9372]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 202
Date solved : `Monday, January 27, 2025 at 06:02:01 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$y'' + \left(t^2+2t+1\right) y' - (4+4t)\, y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.264 (sec)

Writing the ode as

$$y'' + (1+t)^2 y' + (-4-4t)\, y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= (1+t)^2 \\ C &= -4-4t \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(t) = y e^{\int \frac{B}{2A}\,dt}$$

Then (2) becomes

$$z''(t) = r z(t) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{t^4+4t^3+6t^2+24t+21}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= t^4+4t^3+6t^2+24t+21 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(t) = \left(\frac{21}{4} + 6t + \frac{1}{4}t^4 + t^3 + \frac{3}{2}t^2\right) z(t) \tag{7}$$

Equation (7) is now solved. After finding $z(t)$ then y is found using the inverse transformation

$$y = z(t)\, e^{-\int \frac{B}{2A}\, dt}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.382: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 4 \\ &= -4 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -4 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -4$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{4}{2} = 2$$

$[\sqrt{r}]_\infty$ is the sum of terms involving t^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i t^i \\ &= \sum_{i=0}^{2} a_i t^i \end{aligned} \tag{8}$$

Let a be the coefficient of $t^v = t^2$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{t^2}{2} + t + \frac{1}{2} + \frac{5}{t} - \frac{5}{t^2} + \frac{5}{t^3} - \frac{30}{t^4} + \frac{105}{t^5} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 2$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{2} a_i t^i \\ &= \frac{1}{2}t^2 + t + \frac{1}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $t^{v-1} = t^1 = t$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}t^4 + t^3 + \frac{3}{2}t^2 + t + \frac{1}{4}$$

This shows that the coefficient of t in the above is 1. Now we need to find the coefficient of t in r. How this is done depends on if $v = 0$ or not. Since $v = 2$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of t in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{t^4 + 4t^3 + 6t^2 + 24t + 21}{4} \\ &= Q + \frac{R}{4} \\ &= \left(\frac{21}{4} + 6t + \frac{1}{4}t^4 + t^3 + \frac{3}{2}t^2\right) + (0) \\ &= \frac{21}{4} + 6t + \frac{1}{4}t^4 + t^3 + \frac{3}{2}t^2 \end{aligned}$$

We see that the coefficient of the term $\frac{1}{t}$ in the quotient is 6. Now b can be found.

$$\begin{aligned} b &= (6) - (1) \\ &= 5 \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{2}t^2 + t + \frac{1}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{5}{\frac{1}{2}} - 2\right) &= 4 \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{5}{\frac{1}{2}} - 2\right) &= -6 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{21}{4} + 6t + \frac{1}{4}t^4 + t^3 + \frac{3}{2}t^2$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-4	$\frac{1}{2}t^2 + t + \frac{1}{2}$	4	-6

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = 4$, and since there are no poles, then

$$\begin{aligned} d &= \alpha_\infty^+ \\ &= 4 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{t-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= (+)[\sqrt{r}]_\infty \\ &= 0 + \left(\frac{1}{2}t^2 + t + \frac{1}{2}\right) \\ &= \frac{1}{2}t^2 + t + \frac{1}{2} \\ &= \frac{(1+t)^2}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(t)$ of degree $d = 4$ to solve the ode. The polynomial $p(t)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(t) = t^4 + a_3t^3 + a_2t^2 + a_1t + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(12t^2 + 6ta_3 + 2a_2) + 2\left(\frac{1}{2}t^2 + t + \frac{1}{2}\right)(4t^3 + 3t^2a_3 + 2ta_2 + a_1) + \left((1+t) + \left(\frac{1}{2}t^2 + t + \frac{1}{2}\right)^2 - \left(\frac{21}{4} + 6t\right.\right.$$

$$(-a_3 + 4)\, t^4 + 2(2 - a_2 + a_3)\, t^3 + 3(4 - a_1 + a_3)\, t^2 + 2(-2a_0 - a_1 + a_2 + 3a_3)\, t -$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 5, a_1 = 8, a_2 = 6, a_3 = 4\}$$

Substituting these coefficients in $p(t)$ in eq. (2A) results in

$$p(t) = t^4 + 4t^3 + 6t^2 + 8t + 5$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(t) &= pe^{\int \omega\, dt} \\ &= \left(t^4 + 4t^3 + 6t^2 + 8t + 5\right) e^{\int \left(\frac{1}{2}t^2 + t + \frac{1}{2}\right) dt} \\ &= \left(t^4 + 4t^3 + 6t^2 + 8t + 5\right) e^{\frac{(1+t)^3}{6}} \\ &= (1+t)\left(t^3 + 3t^2 + 3t + 5\right) e^{\frac{(1+t)^3}{6}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dt} \\ &= z_1 e^{-\int \frac{1}{2}\frac{(1+t)^2}{1}\, dt} \\ &= z_1 e^{-\frac{(1+t)^3}{6}} \\ &= z_1 \left(e^{-\frac{(1+t)^3}{6}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = (1+t)\left(t^3+3t^2+3t+5\right)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dt}}{y_1^2}\, dt$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{(1+t)^2}{1}\, dt}}{(y_1)^2}\, dt \\ &= y_1 \int \frac{e^{-\frac{(1+t)^3}{3}}}{(y_1)^2}\, dt \\ &= y_1 \left(\int \frac{e^{-\frac{(1+t)^3}{3}}}{(1+t)^2\,(t^3+3t^2+3t+5)^2} dt\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left((1+t)\left(t^3+3t^2+3t+5\right)\right) \\ &\quad + c_2\left((1+t)\left(t^3+3t^2+3t+5\right)\left(\int \frac{e^{-\frac{(1+t)^3}{3}}}{(1+t)^2\,(t^3+3t^2+3t+5)^2} dt\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve
$\frac{d^2}{dt^2}y(t) + (t^2+2t+1)\left(\frac{d}{dt}y(t)\right) - (4t+4)\,y(t) = 0$

- Highest derivative means the order of the ODE is 2
  $\frac{d^2}{dt^2}y(t)$
- Isolate 2nd derivative
  $\frac{d^2}{dt^2}y(t) = -(t^2+2t+1)\left(\frac{d}{dt}y(t)\right) + (4t+4)\,y(t)$
- Group terms with $y(t)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin
  $\frac{d^2}{dt^2}y(t) + (t^2+2t+1)\left(\frac{d}{dt}y(t)\right) + (-4t-4)\,y(t) = 0$
- Assume series solution for $y(t)$
  $y(t) = \sum_{k=0}^{\infty} a_k t^k$

□ Rewrite ODE with series expansions
  - Convert $t^m \cdot y(t)$ to series expansion for $m = 0..1$
    $t^m \cdot y(t) = \sum_{k=\max(0,-m)}^{\infty} a_k t^{k+m}$
  - Shift index using $k->k-m$
    $t^m \cdot y(t) = \sum_{k=\max(0,-m)+m}^{\infty} a_{k-m} t^k$
  - Convert $t^m \cdot \left(\frac{d}{dt}y(t)\right)$ to series expansion for $m = 0..2$

$$t^m \cdot \left(\frac{d}{dt}y(t)\right) = \sum_{k=\max(0,1-m)}^{\infty} a_k k\, t^{k-1+m}$$

- Shift index using $k- >k+1-m$

$$t^m \cdot \left(\frac{d}{dt}y(t)\right) = \sum_{k=\max(0,1-m)+m-1}^{\infty} a_{k+1-m}(k+1-m)\, t^k$$

- Convert $\frac{d^2}{dt^2}y(t)$ to series expansion

$$\frac{d^2}{dt^2}y(t) = \sum_{k=2}^{\infty} a_k k(k-1)\, t^{k-2}$$

- Shift index using $k- >k+2$

$$\frac{d^2}{dt^2}y(t) = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, t^k$$

Rewrite ODE with series expansions

$$2a_2 + a_1 - 4a_0 + \left(\sum_{k=1}^{\infty} \left(a_{k+2}(k+2)\,(k+1) + a_{k+1}(k+1) + 2a_k(k-2) + a_{k-1}(k-5)\right) t^k\right) = 0$$

- Each term must be 0

$$2a_2 + a_1 - 4a_0 = 0$$

- Each term in the series must be 0, giving the recursion relation

$$k^2 a_{k+2} + (2a_k + a_{k-1} + a_{k+1} + 3a_{k+2})\, k - 4a_k - 5a_{k-1} + a_{k+1} + 2a_{k+2} = 0$$

- Shift index using $k- >k+1$

$$(k+1)^2 a_{k+3} + (2a_{k+1} + a_k + a_{k+2} + 3a_{k+3})\,(k+1) - 4a_{k+1} - 5a_k + a_{k+2} + 2a_{k+3} = 0$$

- Recursion relation that defines the series solution to the ODE

$$\left[y(t) = \sum_{k=0}^{\infty} a_k t^k, a_{k+3} = -\frac{a_k k + 2a_{k+1} k + k a_{k+2} - 4a_k - 2a_{k+1} + 2a_{k+2}}{k^2+5k+6}, 2a_2 + a_1 - 4a_0 = 0\right]$$

2.1.201 Problem 204

Internal problem ID [9373]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 204
Date solved : `Monday, January 27, 2025 at 06:02:02 PM`
CAS classification : `[_Laguerre]`

Solve

$$2ty'' + (1 - 2t) y' - y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.223 (sec)

Writing the ode as

$$2ty'' + (1 - 2t) y' - y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2t \\ B &= 1 - 2t \\ C &= -1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(t) = ye^{\int \frac{B}{2A}\, dt}$$

Then (2) becomes

$$z''(t) = rz(t) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{4t^2 + 4t - 3}{16t^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 4t^2 + 4t - 3 \\ t &= 16t^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(t) = \left(\frac{4t^2 + 4t - 3}{16t^2}\right) z(t) \tag{7}$$

Equation (7) is now solved. After finding $z(t)$ then y is found using the inverse transformation

$$y = z(t)\, e^{-\int \frac{B}{2A}\, dt}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.384: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16t^2$. There is a pole at $t = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} - \frac{3}{16t^2} + \frac{1}{4t}$$

For the pole at $t = 0$ let b be the coefficient of $\frac{1}{t^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{4} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving t^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i t^i \\ &= \sum_{i=0}^{0} a_i t^i \end{aligned} \tag{8}$$

Let a be the coefficient of $t^v = t^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} + \frac{1}{4t} - \frac{1}{4t^2} + \frac{1}{8t^3} - \frac{1}{8t^4} + \frac{1}{8t^5} - \frac{9}{64t^6} + \frac{21}{128t^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i t^i \\ &= \frac{1}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $t^{v-1} = t^{-1} = \frac{1}{t}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{t}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{t}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{t}$ in r will be the coefficient in R of the term in t of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{4t^2 + 4t - 3}{16t^2} \\ &= Q + \frac{R}{16t^2} \\ &= \left(\frac{1}{4}\right) + \left(\frac{4t - 3}{16t^2}\right) \\ &= \frac{1}{4} + \frac{4t - 3}{16t^2} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term t in the remainder R is 4. Dividing this by leading coefficient in t which is 16 gives $\frac{1}{4}$. Now b can be found.

$$\begin{aligned} b &= \left(\frac{1}{4}\right) - (0) \\ &= \frac{1}{4} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{\frac{1}{4}}{\frac{1}{2}} - 0\right) &&= \frac{1}{4} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{\frac{1}{4}}{\frac{1}{2}} - 0\right) &&= -\frac{1}{4} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{4t^2 + 4t - 3}{16t^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{3}{4}$	$\frac{1}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	$\frac{1}{4}$	$-\frac{1}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{1}{4}$ then

$$\begin{aligned} d &= \alpha_\infty^+ - (\alpha_{c_1}^-) \\ &= \frac{1}{4} - \left(\frac{1}{4}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{t-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{t-c_1}\right) + (+)[\sqrt{r}]_\infty \\ &= \frac{1}{4t} + \left(\frac{1}{2}\right) \\ &= \frac{1}{2} + \frac{1}{4t} \\ &= \frac{1}{2} + \frac{1}{4t} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(t)$ of degree $d = 0$ to solve the ode. The polynomial $p(t)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(t) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{2} + \frac{1}{4t}\right)(0) + \left(\left(-\frac{1}{4t^2}\right) + \left(\frac{1}{2} + \frac{1}{4t}\right)^2 - \left(\frac{4t^2+4t-3}{16t^2}\right)\right) = 0$$
$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(t) &= p e^{\int \omega\, dt} \\ &= e^{\int \left(\frac{1}{2} + \frac{1}{4t}\right) dt} \\ &= t^{1/4} e^{\frac{t}{2}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dt} \\ &= z_1 e^{-\int \frac{1}{2}\frac{1-2t}{2t}\,dt} \\ &= z_1 e^{\frac{t}{2}-\frac{\ln(t)}{4}} \\ &= z_1 \left(\frac{e^{\frac{t}{2}}}{t^{1/4}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = e^t$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dt}}{y_1^2}\,dt$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{1-2t}{2t}\,dt}}{(y_1)^2}\,dt \\ &= y_1 \int \frac{e^{t-\frac{\ln(t)}{2}}}{(y_1)^2}\,dt \\ &= y_1\left(\sqrt{\pi}\,\mathrm{erf}\left(\sqrt{t}\right)\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(e^t\right) + c_2\left(e^t\left(\sqrt{\pi}\,\mathrm{erf}\left(\sqrt{t}\right)\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$2\left(\frac{d^2}{dt^2}y(t)\right)t + (1-2t)\left(\frac{d}{dt}y(t)\right) - y(t) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dt^2}y(t)$

- Isolate 2nd derivative

  $\frac{d^2}{dt^2}y(t) = \frac{y(t)}{2t} + \frac{(2t-1)\left(\frac{d}{dt}y(t)\right)}{2t}$

- Group terms with $y(t)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d^2}{dt^2}y(t) - \frac{(2t-1)\left(\frac{d}{dt}y(t)\right)}{2t} - \frac{y(t)}{2t} = 0$

- □ Check to see if $t_0 = 0$ is a regular singular point
  - Define functions

    $\left[P_2(t) = -\frac{2t-1}{2t}, P_3(t) = -\frac{1}{2t}\right]$

  - $t \cdot P_2(t)$ is analytic at $t = 0$

$(t \cdot P_2(t))\Big|_{t=0} = \frac{1}{2}$

- ◦ $t^2 \cdot P_3(t)$ is analytic at $t = 0$

  $(t^2 \cdot P_3(t))\Big|_{t=0} = 0$

- ◦ $t = 0$is a regular singular point

  Check to see if $t_0 = 0$ is a regular singular point

  $t_0 = 0$

- Multiply by denominators

  $2\left(\frac{d^2}{dt^2}y(t)\right)t + (1-2t)\left(\frac{d}{dt}y(t)\right) - y(t) = 0$

- Assume series solution for $y(t)$

  $y(t) = \sum_{k=0}^{\infty} a_k t^{k+r}$

- □ Rewrite ODE with series expansions

  - ◦ Convert $t^m \cdot \left(\frac{d}{dt}y(t)\right)$ to series expansion for $m = 0..1$

    $t^m \cdot \left(\frac{d}{dt}y(t)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, t^{k+r-1+m}$

  - ◦ Shift index using $k- >k+1-m$

    $t^m \cdot \left(\frac{d}{dt}y(t)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, t^{k+r}$

  - ◦ Convert $t \cdot \left(\frac{d^2}{dt^2}y(t)\right)$ to series expansion

    $t \cdot \left(\frac{d^2}{dt^2}y(t)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, t^{k+r-1}$

  - ◦ Shift index using $k- >k+1$

    $t \cdot \left(\frac{d^2}{dt^2}y(t)\right) = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)(k+r)\, t^{k+r}$

  Rewrite ODE with series expansions

  $a_0 r(-1+2r)\, t^{-1+r} + \left(\sum_{k=0}^{\infty} \left(a_{k+1}(k+1+r)(2k+2r+1) - a_k(2k+2r+1)\right) t^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r(-1+2r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \left\{0, \frac{1}{2}\right\}$

- Each term in the series must be 0, giving the recursion relation

  $2(a_{k+1}(k+1+r) - a_k)\left(k+r+\frac{1}{2}\right) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+1} = \frac{a_k}{k+1+r}$

- Recursion relation for $r = 0$

  $a_{k+1} = \frac{a_k}{k+1}$

- Solution for $r = 0$

  $\left[y(t) = \sum_{k=0}^{\infty} a_k t^k, a_{k+1} = \frac{a_k}{k+1}\right]$

- Recursion relation for $r = \frac{1}{2}$

  $a_{k+1} = \frac{a_k}{k+\frac{3}{2}}$

- Solution for $r = \frac{1}{2}$

  $\left[y(t) = \sum_{k=0}^{\infty} a_k t^{k+\frac{1}{2}}, a_{k+1} = \frac{a_k}{k+\frac{3}{2}}\right]$

- Combine solutions and rename parameters

$$\left[y(t) = \left(\sum_{k=0}^{\infty} a_k t^k\right) + \left(\sum_{k=0}^{\infty} b_k t^{k+\frac{1}{2}}\right), a_{k+1} = \frac{a_k}{k+1}, b_{k+1} = \frac{b_k}{k+\frac{3}{2}}\right]$$

2.1.202 Problem 205

Internal problem ID [9374]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 205
Date solved : `Monday, January 27, 2025 at 06:02:03 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$2ty'' + (1+t)\,y' - 2y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.394 (sec)

Writing the ode as

$$2ty'' + (1+t)\,y' - 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2t \\ B &= 1+t \\ C &= -2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(t) = ye^{\int \frac{B}{2A}\,dt}$$

Then (2) becomes

$$z''(t) = rz(t) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{t^2 + 18t - 3}{16t^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= t^2 + 18t - 3 \\ t &= 16t^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(t) = \left(\frac{t^2 + 18t - 3}{16t^2}\right) z(t) \tag{7}$$

Equation (7) is now solved. After finding $z(t)$ then y is found using the inverse transformation

$$y = z(t)\, e^{-\int \frac{B}{2A}\, dt}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.386: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16t^2$. There is a pole at $t = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{16} - \frac{3}{16t^2} + \frac{9}{8t}$$

For the pole at $t = 0$ let b be the coefficient of $\frac{1}{t^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{4} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving t^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i t^i \\ &= \sum_{i=0}^{0} a_i t^i \end{aligned} \tag{8}$$

Let a be the coefficient of $t^v = t^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{4} + \frac{9}{4t} - \frac{21}{2t^2} + \frac{189}{2t^3} - \frac{1071}{t^4} + \frac{13608}{t^5} - \frac{370629}{2t^6} + \frac{5288409}{2t^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{4}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i t^i \\ &= \frac{1}{4} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $t^{v-1} = t^{-1} = \frac{1}{t}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{16}$$

This shows that the coefficient of $\frac{1}{t}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{t}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{t}$ in r will be the coefficient in R of the term in t of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{t^2 + 18t - 3}{16t^2} \\ &= Q + \frac{R}{16t^2} \\ &= \left(\frac{1}{16}\right) + \left(\frac{18t - 3}{16t^2}\right) \\ &= \frac{1}{16} + \frac{18t - 3}{16t^2} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term t in the remainder R is 18. Dividing this by leading coefficient in t which is 16 gives $\frac{9}{8}$. Now b can be found.

$$\begin{aligned} b &= \left(\frac{9}{8}\right) - (0) \\ &= \frac{9}{8} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{4} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{\frac{9}{8}}{\frac{1}{4}} - 0\right) &&= \frac{9}{4} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{\frac{9}{8}}{\frac{1}{4}} - 0\right) &&= -\frac{9}{4} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{t^2 + 18t - 3}{16t^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{3}{4}$	$\frac{1}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{4}$	$\frac{9}{4}$	$-\frac{9}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{9}{4}$ then

$$\begin{aligned} d &= \alpha_\infty^+ - \left(\alpha_{c_1}^-\right) \\ &= \frac{9}{4} - \left(\frac{1}{4}\right) \\ &= 2 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{t-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{t-c_1} \right) + (+)[\sqrt{r}]_\infty \\ &= \frac{1}{4t} + \left(\frac{1}{4}\right) \\ &= \frac{1}{4t} + \frac{1}{4} \\ &= \frac{1+t}{4t} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(t)$ of degree $d = 2$ to solve the ode. The polynomial $p(t)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(t) = t^2 + a_1 t + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(2) + 2\left(\frac{1}{4t} + \frac{1}{4}\right)(2t + a_1) + \left(\left(-\frac{1}{4t^2}\right) + \left(\frac{1}{4t} + \frac{1}{4}\right)^2 - \left(\frac{t^2 + 18t - 3}{16t^2}\right)\right) = 0$$

$$\frac{(-a_1 + 6)\, t - 2a_0 + a_1}{2t} = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 3, a_1 = 6\}$$

Substituting these coefficients in $p(t)$ in eq. (2A) results in

$$p(t) = t^2 + 6t + 3$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(t) &= p e^{\int \omega \, dt} \\ &= \left(t^2+6t+3\right) e^{\int \left(\frac{1}{4t}+\frac{1}{4}\right)dt} \\ &= \left(t^2+6t+3\right) e^{\frac{t}{4}+\frac{\ln(t)}{4}} \\ &= \left(t^2+6t+3\right) t^{1/4} e^{\frac{t}{4}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dt} \\ &= z_1 e^{-\int \frac{1}{2}\frac{1+t}{2t}\, dt} \\ &= z_1 e^{-\frac{t}{4}-\frac{\ln(t)}{4}} \\ &= z_1 \left(\frac{e^{-\frac{t}{4}}}{t^{1/4}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = t^2+6t+3$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dt}}{y_1^2}\, dt$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{1+t}{2t}\, dt}}{(y_1)^2}\, dt \\ &= y_1 \int \frac{e^{-\frac{t}{2}-\frac{\ln(t)}{2}}}{(y_1)^2}\, dt \\ &= y_1 \left(\int \frac{e^{-\frac{t}{2}-\frac{\ln(t)}{2}}}{\left(t^2+6t+3\right)^2} dt\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(t^2+6t+3\right) + c_2\left(t^2+6t+3\left(\int \frac{e^{-\frac{t}{2}-\frac{\ln(t)}{2}}}{\left(t^2+6t+3\right)^2} dt\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve
$2\left(\frac{d^2}{dt^2}y(t)\right)t + (t+1)\left(\frac{d}{dt}y(t)\right) - 2y(t) = 0$

- Highest derivative means the order of the ODE is 2
$\frac{d^2}{dt^2}y(t)$

Problem number : 206
Date solved : `Monday, January 27, 2025 at 06:02:03 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$2t^2y'' - ty' + (1+t)\,y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.212 (sec)

Writing the ode as

$$2t^2y'' - ty' + (1+t)\,y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2t^2 \\ B &= -t \\ C &= 1+t \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(t) = ye^{\int \frac{B}{2A}\,dt}$$

Then (2) becomes

$$z''(t) = rz(t) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-3-8t}{16t^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -3-8t \\ t &= 16t^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(t) = \left(\frac{-3-8t}{16t^2}\right) z(t) \tag{7}$$

Equation (7) is now solved. After finding $z(t)$ then y is found using the inverse transformation

$$y = z(t)\, e^{-\int \frac{B}{2A}\, dt}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.388: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 1 \\ &= 1 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16t^2$. There is a pole at $t = 0$ of order 2. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [2]$$

Attempting to find a solution using case $n = 2$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{3}{16t^2} - \frac{1}{2t}$$

For the pole at $t = 0$ let b be the coefficient of $\frac{1}{t^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} E_c &= \{2, 2 + 2\sqrt{1 + 4b}, 2 - 2\sqrt{1 + 4b}\} \\ &= \{1, 2, 3\} \end{aligned}$$

Since the order of r at ∞ is $1 < 2$ then

$$E_\infty = \{1\}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ for case 2 of Kovacic algorithm.

pole c location	pole order	E_c
0	2	$\{1, 2, 3\}$

Order of r at ∞	E_∞
1	$\{1\}$

Using the family $\{e_1, e_2, \ldots, e_\infty\}$ given by

$$e_1 = 1, \; e_\infty = 1$$

Gives a non negative integer d (the degree of the polynomial $p(t)$), which is generated using

$$\begin{aligned} d &= \frac{1}{2}\left(e_\infty - \sum_{c\in\Gamma} e_c\right) \\ &= \frac{1}{2}(1 - (1)) \\ &= 0 \end{aligned}$$

We now form the following rational function

$$\begin{aligned} \theta &= \frac{1}{2}\sum_{c\in\Gamma} \frac{e_c}{t-c} \\ &= \frac{1}{2}\left(\frac{1}{(t-(0))}\right) \\ &= \frac{1}{2t} \end{aligned}$$

Now we search for a monic polynomial $p(t)$ of degree $d = 0$ such that

$$p''' + 3\theta p'' + \left(3\theta^2 + 3\theta' - 4r\right)p' + \left(\theta'' + 3\theta\theta' + \theta^3 - 4r\theta - 2r'\right)p = 0 \tag{1A}$$

Since $d = 0$, then letting

$$p = 1 \tag{2A}$$

Substituting p and θ into Eq. (1A) gives

$$0 = 0$$

And solving for p gives

$$p = 1$$

Now that $p(t)$ is found let

$$\begin{aligned} \phi &= \theta + \frac{p'}{p} \\ &= \frac{1}{2t} \end{aligned}$$

Let ω be the solution of

$$\omega^2 - \phi\omega + \left(\frac{1}{2}\phi' + \frac{1}{2}\phi^2 - r\right) = 0$$

Substituting the values for ϕ and r into the above equation gives

$$w^2 - \frac{w}{2t} + \frac{1+8t}{16t^2} = 0$$

Solving for ω gives

$$\omega = \frac{1 + 2\sqrt{2}\,\sqrt{-t}}{4t}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(t) &= e^{\int \omega\, dt} \\ &= \mathrm{e}^{\int \frac{1+2\sqrt{2}\,\sqrt{-t}}{4t} dt} \\ &= t^{1/4} \mathrm{e}^{\sqrt{2}\,\sqrt{-t}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dt} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-t}{2t^2}\,dt} \\ &= z_1 e^{\frac{\ln(t)}{4}} \\ &= z_1 \left(t^{1/4}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \sqrt{t}\,\mathrm{e}^{\sqrt{2}\sqrt{-t}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dt}}{y_1^2}\,dt$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-t}{2t^2}\,dt}}{(y_1)^2}\,dt \\ &= y_1 \int \frac{e^{\frac{\ln(t)}{2}}}{(y_1)^2}\,dt \\ &= y_1 \left(-\frac{\sqrt{2}\sqrt{-t}\left(1-\mathrm{e}^{-2\sqrt{2}\sqrt{-t}}\right)}{2\sqrt{t}}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\sqrt{t}\,\mathrm{e}^{\sqrt{2}\sqrt{-t}}\right) + c_2\left(\sqrt{t}\,\mathrm{e}^{\sqrt{2}\sqrt{-t}}\left(-\frac{\sqrt{2}\sqrt{-t}\left(1-\mathrm{e}^{-2\sqrt{2}\sqrt{-t}}\right)}{2\sqrt{t}}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

    $t \cdot \left(\frac{d}{dt}y(t)\right) = \sum_{k=0}^{\infty} a_k (k+r)\, t^{k+r}$

  - Convert $t^2 \cdot \left(\frac{d^2}{dt^2}y(t)\right)$ to series expansion

    $t^2 \cdot \left(\frac{d^2}{dt^2}y(t)\right) = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, t^{k+r}$

  Rewrite ODE with series expansions

  $a_0(-1+2r)\,(-1+r)\, t^r + \left(\sum_{k=1}^{\infty} \left(a_k(2k+2r-1)\,(k+r-1) + a_{k-1}\right) t^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-1+2r)\,(-1+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \left\{1, \frac{1}{2}\right\}$

- Each term in the series must be 0, giving the recursion relation

  $2\left(k+r-\frac{1}{2}\right)(k+r-1)\, a_k + a_{k-1} = 0$

- Shift index using $k- >k + 1$

  $2\left(k+\frac{1}{2}+r\right)(k+r)\, a_{k+1} + a_k = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+1} = -\frac{a_k}{(2k+1+2r)(k+r)}$

- Recursion relation for $r = 1$

  $a_{k+1} = -\frac{a_k}{(2k+3)(k+1)}$

- Solution for $r = 1$

  $\left[y(t) = \sum_{k=0}^{\infty} a_k t^{k+1}, a_{k+1} = -\frac{a_k}{(2k+3)(k+1)}\right]$

- Recursion relation for $r = \frac{1}{2}$

  $a_{k+1} = -\frac{a_k}{(2k+2)\left(k+\frac{1}{2}\right)}$

- Solution for $r = \frac{1}{2}$

$$\left[y(t)=\sum_{k=0}^{\infty} a_k t^{k+\frac{1}{2}}, a_{k+1}=-\frac{a_k}{(2k+2)\left(k+\frac{1}{2}\right)}\right]$$

- Combine solutions and rename parameters

$$\left[y(t)=\left(\sum_{k=0}^{\infty} a_k t^{k+1}\right)+\left(\sum_{k=0}^{\infty} b_k t^{k+\frac{1}{2}}\right), a_{k+1}=-\frac{a_k}{(2k+3)(k+1)}, b_{k+1}=-\frac{b_k}{(2k+2)\left(k+\frac{1}{2}\right)}\right]$$

2.1.204 Problem 207

Internal problem ID [9376]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 207
Date solved : Monday, January 27, 2025 at 06:02:04 PM
CAS classification : [[_2nd_order, _with_linear_symmetries]]

Solve

$$2t^2y'' + (t^2 - t)\, y' + y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.230 (sec)

Writing the ode as

$$2t^2y'' + (t^2 - t)\, y' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2t^2 \\ B &= t^2 - t \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(t) = y e^{\int \frac{B}{2A}\, dt}$$

Then (2) becomes

$$z''(t) = rz(t) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{t^2 - 2t - 3}{16t^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= t^2 - 2t - 3 \\ t &= 16t^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(t) = \left(\frac{t^2 - 2t - 3}{16t^2}\right) z(t) \tag{7}$$

Equation (7) is now solved. After finding $z(t)$ then y is found using the inverse transformation

$$y = z(t)\, e^{-\int \frac{B}{2A}\, dt}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.390: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16t^2$. There is a pole at $t = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{16} - \frac{3}{16t^2} - \frac{1}{8t}$$

For the pole at $t = 0$ let b be the coefficient of $\frac{1}{t^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{3}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{4} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving t^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i t^i \\ &= \sum_{i=0}^{0} a_i t^i \end{aligned} \tag{8}$$

Let a be the coefficient of $t^v = t^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{4} - \frac{1}{4t} - \frac{1}{2t^2} - \frac{1}{2t^3} - \frac{1}{t^4} - \frac{2}{t^5} - \frac{9}{2t^6} - \frac{21}{2t^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{4}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i t^i \\ &= \frac{1}{4}\end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $t^{v-1} = t^{-1} = \frac{1}{t}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{16}$$

This shows that the coefficient of $\frac{1}{t}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{t}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{t}$ in r will be the coefficient in R of the term in t of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned}r &= \frac{s}{t} \\ &= \frac{t^2 - 2t - 3}{16t^2} \\ &= Q + \frac{R}{16t^2} \\ &= \left(\frac{1}{16}\right) + \left(\frac{-2t - 3}{16t^2}\right) \\ &= \frac{1}{16} + \frac{-2t - 3}{16t^2}\end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term t in the remainder R is -2. Dividing this by leading coefficient in t which is 16 gives $-\frac{1}{8}$. Now b can be found.

$$\begin{aligned}b &= \left(-\frac{1}{8}\right) - (0) \\ &= -\frac{1}{8}\end{aligned}$$

Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= \frac{1}{4} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{1}{8}}{\frac{1}{4}} - 0\right) &&= -\frac{1}{4} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{1}{8}}{\frac{1}{4}} - 0\right) &&= \frac{1}{4}\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{t^2 - 2t - 3}{16t^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{3}{4}$	$\frac{1}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{4}$	$-\frac{1}{4}$	$\frac{1}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{4}$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\ &= \frac{1}{4} - \left(\frac{1}{4}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{t-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{t-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{1}{4t} + (-)\left(\frac{1}{4}\right) \\ &= \frac{1}{4t} - \frac{1}{4} \\ &= -\frac{t-1}{4t} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(t)$ of degree $d = 0$ to solve the ode. The polynomial $p(t)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(t) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(\frac{1}{4t} - \frac{1}{4}\right)(0) + \left(\left(-\frac{1}{4t^2}\right) + \left(\frac{1}{4t} - \frac{1}{4}\right)^2 - \left(\frac{t^2-2t-3}{16t^2}\right) \right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(t) &= p e^{\int \omega \, dt} \\ &= e^{\int \left(\frac{1}{4t} - \frac{1}{4}\right) dt} \\ &= t^{1/4} e^{-\frac{t}{4}} \end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dt} \\
&= z_1 e^{-\int \frac{1}{2}\frac{t^2-t}{2t^2}\,dt} \\
&= z_1 e^{-\frac{t}{4}+\frac{\ln(t)}{4}} \\
&= z_1\left(t^{1/4}\mathrm{e}^{-\frac{t}{4}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \sqrt{t}\,\mathrm{e}^{-\frac{t}{2}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dt}}{y_1^2}\,dt
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{t^2-t}{2t^2}\,dt}}{(y_1)^2}\,dt \\
&= y_1 \int \frac{e^{-\frac{t}{2}+\frac{\ln(t)}{2}}}{(y_1)^2}\,dt \\
&= y_1\left(-i\sqrt{\pi}\,\sqrt{2}\,\operatorname{erf}\left(\frac{i\sqrt{2}\,\sqrt{t}}{2}\right)\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\sqrt{t}\,\mathrm{e}^{-\frac{t}{2}}\right) + c_2\left(\sqrt{t}\,\mathrm{e}^{-\frac{t}{2}}\left(-i\sqrt{\pi}\,\sqrt{2}\,\operatorname{erf}\left(\frac{i\sqrt{2}\,\sqrt{t}}{2}\right)\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$2\left(\frac{d^2}{dt^2}y(t)\right)t^2 + (t^2-t)\left(\frac{d}{dt}y(t)\right) + y(t) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dt^2}y(t)$

- Isolate 2nd derivative

  $\frac{d^2}{dt^2}y(t) = -\frac{y(t)}{2t^2} - \frac{(t-1)\left(\frac{d}{dt}y(t)\right)}{2t}$

- Group terms with $y(t)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dt^2}y(t) + \frac{(t-1)\left(\frac{d}{dt}y(t)\right)}{2t} + \frac{y(t)}{2t^2} = 0$

☐ Check to see if $t_0 = 0$ is a regular singular point

- ○ Define functions

  $\left[P_2(t) = \frac{t-1}{2t}, P_3(t) = \frac{1}{2t^2}\right]$

- ○ $t \cdot P_2(t)$ is analytic at $t = 0$

$\left(t \cdot P_2(t)\right)\Big|_{t=0} = -\frac{1}{2}$

- ◦ $t^2 \cdot P_3(t)$ is analytic at $t = 0$

  $\left(t^2 \cdot P_3(t)\right)\Big|_{t=0} = \frac{1}{2}$

- ◦ $t = 0$is a regular singular point

  Check to see if $t_0 = 0$ is a regular singular point

  $t_0 = 0$

- Multiply by denominators

  $2\left(\frac{d^2}{dt^2}y(t)\right)t^2 + t(t-1)\left(\frac{d}{dt}y(t)\right) + y(t) = 0$

- Assume series solution for $y(t)$

  $y(t) = \sum_{k=0}^{\infty} a_k t^{k+r}$

- □ Rewrite ODE with series expansions

  - ◦ Convert $t^m \cdot \left(\frac{d}{dt}y(t)\right)$ to series expansion for $m = 1..2$

    $t^m \cdot \left(\frac{d}{dt}y(t)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, t^{k+r-1+m}$

  - ◦ Shift index using $k- >k+1-m$

    $t^m \cdot \left(\frac{d}{dt}y(t)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, t^{k+r}$

  - ◦ Convert $t^2 \cdot \left(\frac{d^2}{dt^2}y(t)\right)$ to series expansion

    $t^2 \cdot \left(\frac{d^2}{dt^2}y(t)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, t^{k+r}$

  Rewrite ODE with series expansions

  $a_0(-1+2r)(-1+r)\, t^r + \left(\sum_{k=1}^{\infty} \left(a_k(2k+2r-1)(k+r-1) + a_{k-1}(k+r-1)\right) t^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-1+2r)(-1+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \left\{1, \frac{1}{2}\right\}$

- Each term in the series must be 0, giving the recursion relation

  $2\left(\left(k+r-\frac{1}{2}\right)a_k + \frac{a_{k-1}}{2}\right)(k+r-1) = 0$

- Shift index using $k- >k+1$

  $2\left(\left(k+\frac{1}{2}+r\right)a_{k+1} + \frac{a_k}{2}\right)(k+r) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+1} = -\frac{a_k}{2k+1+2r}$

- Recursion relation for $r = 1$

  $a_{k+1} = -\frac{a_k}{2k+3}$

- Solution for $r = 1$

  $\left[y(t) = \sum_{k=0}^{\infty} a_k t^{k+1}, a_{k+1} = -\frac{a_k}{2k+3}\right]$

- Recursion relation for $r = \frac{1}{2}$

  $a_{k+1} = -\frac{a_k}{2k+2}$

- Solution for $r = \frac{1}{2}$

  $\left[y(t) = \sum_{k=0}^{\infty} a_k t^{k+\frac{1}{2}}, a_{k+1} = -\frac{a_k}{2k+2}\right]$

- Combine solutions and rename parameters

$$\left[y(t)=\left(\sum_{k=0}^{\infty}a_k t^{k+1}\right)+\left(\sum_{k=0}^{\infty}b_k t^{k+\frac{1}{2}}\right), a_{k+1}=-\frac{a_k}{2k+3}, b_{k+1}=-\frac{b_k}{2k+2}\right]$$

2.1.205 Problem 208

Internal problem ID [9377]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 208
Date solved : Monday, January 27, 2025 at 06:02:05 PM
CAS classification : [[_2nd_order, _with_linear_symmetries]]

Solve

$$t^2y'' + \left(-t^2 + t\right) y' - y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.207 (sec)

Writing the ode as

$$t^2y'' + \left(-t^2 + t\right) y' - y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= t^2 \\ B &= -t^2 + t \\ C &= -1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(t) = ye^{\int \frac{B}{2A}\,dt}$$

Then (2) becomes

$$z''(t) = rz(t) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{t^2 - 2t + 3}{4t^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= t^2 - 2t + 3 \\ t &= 4t^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(t) = \left(\frac{t^2 - 2t + 3}{4t^2}\right) z(t) \tag{7}$$

Equation (7) is now solved. After finding $z(t)$ then y is found using the inverse transformation

$$y = z(t)\, e^{-\int \frac{B}{2A}\, dt}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.392: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4t^2$. There is a pole at $t = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} + \frac{3}{4t^2} - \frac{1}{2t}$$

For the pole at $t = 0$ let b be the coefficient of $\frac{1}{t^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving t^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i t^i \\ &= \sum_{i=0}^{0} a_i t^i \end{aligned} \tag{8}$$

Let a be the coefficient of $t^v = t^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} - \frac{1}{2t} + \frac{1}{2t^2} + \frac{1}{2t^3} + \frac{1}{4t^4} - \frac{1}{4t^5} - \frac{3}{4t^6} - \frac{3}{4t^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i t^i \\ &= \frac{1}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $t^{v-1} = t^{-1} = \frac{1}{t}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{t}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{t}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{t}$ in r will be the coefficient in R of the term in t of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{t^2 - 2t + 3}{4t^2} \\ &= Q + \frac{R}{4t^2} \\ &= \left(\frac{1}{4}\right) + \left(\frac{-2t + 3}{4t^2}\right) \\ &= \frac{1}{4} + \frac{-2t + 3}{4t^2} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term t in the remainder R is -2. Dividing this by leading coefficient in t which is 4 gives $-\frac{1}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{1}{2}\right) - (0) \\ &= -\frac{1}{2} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &&= -\frac{1}{2} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &&= \frac{1}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{t^2 - 2t + 3}{4t^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	$-\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = -\frac{1}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^+ - (\alpha_{c_1}^-) \\
&= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{t-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{t-c_1} \right) + (+)[\sqrt{r}]_\infty \\
&= -\frac{1}{2t} + \left(\frac{1}{2}\right) \\
&= \frac{1}{2} - \frac{1}{2t} \\
&= \frac{t-1}{2t}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(t)$ of degree $d = 0$ to solve the ode. The polynomial $p(t)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(t) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned}
(0) + 2\left(\frac{1}{2} - \frac{1}{2t}\right)(0) + \left(\left(\frac{1}{2t^2}\right) + \left(\frac{1}{2} - \frac{1}{2t}\right)^2 - \left(\frac{t^2-2t+3}{4t^2}\right) \right) &= 0 \\
0 &= 0
\end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(t) &= p e^{\int \omega\, dt} \\
&= e^{\int \left(\frac{1}{2} - \frac{1}{2t}\right) dt} \\
&= \frac{e^{\frac{t}{2}}}{\sqrt{t}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dt} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-t^2+t}{t^2}\,dt} \\ &= z_1 e^{\frac{t}{2}-\frac{\ln(t)}{2}} \\ &= z_1\left(\frac{e^{\frac{t}{2}}}{\sqrt{t}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{e^t}{t}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dt}}{y_1^2}\,dt$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-t^2+t}{t^2}\,dt}}{(y_1)^2}\,dt \\ &= y_1 \int \frac{e^{t-\ln(t)}}{(y_1)^2}\,dt \\ &= y_1\left(-(1+t)\,t\,e^{t-\ln(t)}e^{-2t}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\frac{e^t}{t}\right) + c_2\left(\frac{e^t}{t}\left(-(1+t)\,t\,e^{t-\ln(t)}e^{-2t}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve
$\left(\frac{d^2}{dt^2}y(t)\right)t^2 + (-t^2+t)\left(\frac{d}{dt}y(t)\right) - y(t) = 0$

- Highest derivative means the order of the ODE is 2
  $\frac{d^2}{dt^2}y(t)$
- Isolate 2nd derivative
  $\frac{d^2}{dt^2}y(t) = \frac{y(t)}{t^2} + \frac{(t-1)\left(\frac{d}{dt}y(t)\right)}{t}$
- Group terms with $y(t)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear
  $\frac{d^2}{dt^2}y(t) - \frac{(t-1)\left(\frac{d}{dt}y(t)\right)}{t} - \frac{y(t)}{t^2} = 0$

□ Check to see if $t_0 = 0$ is a regular singular point
  - Define functions
    $\left[P_2(t) = -\frac{t-1}{t}, P_3(t) = -\frac{1}{t^2}\right]$
  - $t \cdot P_2(t)$ is analytic at $t = 0$

$(t \cdot P_2(t))\Big|_{t=0} = 1$

- ◦ $t^2 \cdot P_3(t)$ is analytic at $t = 0$

  $(t^2 \cdot P_3(t))\Big|_{t=0} = -1$

- ◦ $t = 0$is a regular singular point

  Check to see if $t_0 = 0$ is a regular singular point

  $t_0 = 0$

- Multiply by denominators

  $\left(\frac{d^2}{dt^2}y(t)\right)t^2 - t(t-1)\left(\frac{d}{dt}y(t)\right) - y(t) = 0$

- Assume series solution for $y(t)$

  $y(t) = \sum_{k=0}^{\infty} a_k t^{k+r}$

- □ Rewrite ODE with series expansions

  - ◦ Convert $t^m \cdot \left(\frac{d}{dt}y(t)\right)$ to series expansion for $m = 1..2$

    $t^m \cdot \left(\frac{d}{dt}y(t)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, t^{k+r-1+m}$

  - ◦ Shift index using $k- >k+1-m$

    $t^m \cdot \left(\frac{d}{dt}y(t)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, t^{k+r}$

  - ◦ Convert $t^2 \cdot \left(\frac{d^2}{dt^2}y(t)\right)$ to series expansion

    $t^2 \cdot \left(\frac{d^2}{dt^2}y(t)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, t^{k+r}$

  Rewrite ODE with series expansions

  $a_0(1+r)(-1+r)\, t^r + \left(\sum_{k=1}^{\infty} (a_k(k+r+1)(k+r-1) - a_{k-1}(k+r-1))\, t^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(1+r)(-1+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{-1, 1\}$

- Each term in the series must be 0, giving the recursion relation

  $(k+r-1)(a_k(k+r+1) - a_{k-1}) = 0$

- Shift index using $k- >k+1$

  $(k+r)(a_{k+1}(k+2+r) - a_k) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+1} = \frac{a_k}{k+2+r}$

- Recursion relation for $r = -1$

  $a_{k+1} = \frac{a_k}{k+1}$

- Solution for $r = -1$

  $\left[y(t) = \sum_{k=0}^{\infty} a_k t^{k-1}, a_{k+1} = \frac{a_k}{k+1}\right]$

- Recursion relation for $r = 1$

  $a_{k+1} = \frac{a_k}{k+3}$

- Solution for $r = 1$

  $\left[y(t) = \sum_{k=0}^{\infty} a_k t^{k+1}, a_{k+1} = \frac{a_k}{k+3}\right]$

- Combine solutions and rename parameters

  $\left[y(t) = \left(\sum_{k=0}^{\infty} a_k t^{k-1}\right) + \left(\sum_{k=0}^{\infty} b_k t^{k+1}\right), a_{k+1} = \frac{a_k}{k+1}, b_{k+1} = \frac{b_k}{k+3}\right]$

CAS classification : `[_Lienard]`

Solve

$$ty'' - \left(t^2 + 2\right) y' + ty = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.262 (sec)

Writing the ode as

$$ty'' + \left(-t^2 - 2\right) y' + ty = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= t \\ B &= -t^2 - 2 \\ C &= t \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(t) = ye^{\int \frac{B}{2A} dt}$$

Then (2) becomes

$$z''(t) = rz(t) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{t^4 - 2t^2 + 8}{4t^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= t^4 - 2t^2 + 8 \\ t &= 4t^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(t) = \left(\frac{t^4 - 2t^2 + 8}{4t^2}\right) z(t) \tag{7}$$

Equation (7) is now solved. After finding $z(t)$ then y is found using the inverse transformation

$$y = z(t)\, e^{-\int \frac{B}{2A}\, dt}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.394: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 2 - 4 \\
&= -2
\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4t^2$. There is a pole at $t = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{t^2}{4} - \frac{1}{2} + \frac{2}{t^2}$$

For the pole at $t = 0$ let b be the coefficient of $\frac{1}{t^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1
\end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving t^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i t^i \\
&= \sum_{i=0}^{1} a_i t^i \qquad (8)
\end{aligned}$$

Let a be the coefficient of $t^v = t^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{t}{2} - \frac{1}{2t} + \frac{7}{4t^3} + \frac{7}{4t^5} - \frac{21}{16t^7} - \frac{119}{16t^9} - \frac{189}{32t^{11}} + \frac{791}{32t^{13}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i t^i \\ &= \frac{t}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $t^{v-1} = t^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{t^2}{4}$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{t^4 - 2t^2 + 8}{4t^2} \\ &= Q + \frac{R}{4t^2} \\ &= \left(\frac{t^2}{4} - \frac{1}{2}\right) + \left(\frac{2}{t^2}\right) \\ &= \frac{t^2}{4} - \frac{1}{2} + \frac{2}{t^2} \end{aligned}$$

We see that the coefficient of the term t in the quotient is $-\frac{1}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{1}{2}\right) - (0) \\ &= -\frac{1}{2} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{t}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{1}{2}}{\frac{1}{2}} - 1\right) &&= -1 \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{1}{2}}{\frac{1}{2}} - 1\right) &&= 0 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{t^4 - 2t^2 + 8}{4t^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	2	-1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-2	$\frac{t}{2}$	-1	0

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = -1$ then

$$\begin{aligned} d &= \alpha_\infty^+ - \left(\alpha_{c_1}^-\right) \\ &= -1 - (-1) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{t-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{t-c_1} \right) + (+)[\sqrt{r}]_\infty \\ &= -\frac{1}{t} + \left(\frac{t}{2}\right) \\ &= -\frac{1}{t} + \frac{t}{2} \\ &= -\frac{1}{t} + \frac{t}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(t)$ of degree $d = 0$ to solve the ode. The polynomial $p(t)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(t) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(-\frac{1}{t} + \frac{t}{2}\right)(0) + \left(\left(\frac{1}{t^2} + \frac{1}{2}\right) + \left(-\frac{1}{t} + \frac{t}{2}\right)^2 - \left(\frac{t^4 - 2t^2 + 8}{4t^2}\right)\right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(t) &= p e^{\int \omega \, dt} \\ &= e^{\int \left(-\frac{1}{t} + \frac{t}{2}\right) dt} \\ &= \frac{e^{\frac{t^2}{4}}}{t} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dt} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-t^2-2}{t}\,dt} \\
&= z_1 e^{\frac{t^2}{4}+\ln(t)} \\
&= z_1\left(t\,\mathrm{e}^{\frac{t^2}{4}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{\frac{t^2}{2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dt}}{y_1^2}\,dt$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-t^2-2}{t}\,dt}}{(y_1)^2}\,dt \\
&= y_1 \int \frac{e^{\frac{t^2}{2}+2\ln(t)}}{(y_1)^2}\,dt \\
&= y_1\left(-t\,\mathrm{e}^{-\frac{t^2}{2}} + \frac{\sqrt{\pi}\,\sqrt{2}\,\operatorname{erf}\left(\frac{\sqrt{2}\,t}{2}\right)}{2}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{\frac{t^2}{2}}\right) + c_2\left(\mathrm{e}^{\frac{t^2}{2}}\left(-t\,\mathrm{e}^{-\frac{t^2}{2}} + \frac{\sqrt{\pi}\,\sqrt{2}\,\operatorname{erf}\left(\frac{\sqrt{2}\,t}{2}\right)}{2}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$\left(\frac{d^2}{dt^2}y(t)\right)t - (t^2+2)\left(\frac{d}{dt}y(t)\right) + ty(t) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dt^2}y(t)$

- Isolate 2nd derivative

  $\frac{d^2}{dt^2}y(t) = -y(t) + \frac{(t^2+2)\left(\frac{d}{dt}y(t)\right)}{t}$

2.1.207 Problem 210

Internal problem ID [9379]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 210
Date solved : `Monday, January 27, 2025 at 06:02:06 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$t^2y'' + t(t+1)\,y' - y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.205 (sec)

Writing the ode as

$$t^2y'' + \left(t^2+t\right)y' - y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= t^2 \\ B &= t^2+t \\ C &= -1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(t) = ye^{\int \frac{B}{2A}\,dt}$$

Then (2) becomes

$$z''(t) = rz(t) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{t^2+2t+3}{4t^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= t^2+2t+3 \\ t &= 4t^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(t) = \left(\frac{t^2+2t+3}{4t^2}\right)z(t) \tag{7}$$

Equation (7) is now solved. After finding $z(t)$ then y is found using the inverse transformation

$$y = z(t)\, e^{-\int \frac{B}{2A}\, dt}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.396: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4t^2$. There is a pole at $t = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} + \frac{1}{2t} + \frac{3}{4t^2}$$

For the pole at $t = 0$ let b be the coefficient of $\frac{1}{t^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving t^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i t^i \\ &= \sum_{i=0}^{0} a_i t^i \end{aligned} \tag{8}$$

Let a be the coefficient of $t^v = t^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} + \frac{1}{2t} + \frac{1}{2t^2} - \frac{1}{2t^3} + \frac{1}{4t^4} + \frac{1}{4t^5} - \frac{3}{4t^6} + \frac{3}{4t^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i t^i \\ &= \frac{1}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $t^{v-1} = t^{-1} = \frac{1}{t}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{t}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{t}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{t}$ in r will be the coefficient in R of the term in t of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{t^2 + 2t + 3}{4t^2} \\ &= Q + \frac{R}{4t^2} \\ &= \left(\frac{1}{4}\right) + \left(\frac{2t + 3}{4t^2}\right) \\ &= \frac{1}{4} + \frac{2t + 3}{4t^2} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term t in the remainder R is 2. Dividing this by leading coefficient in t which is 4 gives $\frac{1}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(\frac{1}{2}\right) - (0) \\ &= \frac{1}{2} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{\frac{1}{2}}{\frac{1}{2}} - 0\right) &= \frac{1}{2} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{\frac{1}{2}}{\frac{1}{2}} - 0\right) &= -\frac{1}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{t^2 + 2t + 3}{4t^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	$\frac{1}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -\frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\ &= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{t-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{t-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= -\frac{1}{2t} + (-)\left(\frac{1}{2}\right) \\ &= -\frac{1}{2t} - \frac{1}{2} \\ &= -\frac{t+1}{2t} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(t)$ of degree $d = 0$ to solve the ode. The polynomial $p(t)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(t) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(-\frac{1}{2t} - \frac{1}{2}\right)(0) + \left(\left(\frac{1}{2t^2}\right) + \left(-\frac{1}{2t} - \frac{1}{2}\right)^2 - \left(\frac{t^2+2t+3}{4t^2}\right)\right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(t) &= p e^{\int \omega \, dt} \\ &= e^{\int \left(-\frac{1}{2t} - \frac{1}{2}\right) dt} \\ &= \frac{e^{-\frac{t}{2}}}{\sqrt{t}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dt} \\ &= z_1 e^{-\int \frac{1}{2}\frac{t^2+t}{t^2}\,dt} \\ &= z_1 e^{-\frac{t}{2}-\frac{\ln(t)}{2}} \\ &= z_1\left(\frac{\mathrm{e}^{-\frac{t}{2}}}{\sqrt{t}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{\mathrm{e}^{-t}}{t}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dt}}{y_1^2}\,dt$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{t^2+t}{t^2}\,dt}}{(y_1)^2}\,dt \\ &= y_1 \int \frac{e^{-t-\ln(t)}}{(y_1)^2}\,dt \\ &= y_1\left((-1+t)\,t\,\mathrm{e}^{-t-\ln(t)}\mathrm{e}^{2t}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\frac{\mathrm{e}^{-t}}{t}\right) + c_2\left(\frac{\mathrm{e}^{-t}}{t}\left((-1+t)\,t\,\mathrm{e}^{-t-\ln(t)}\mathrm{e}^{2t}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

2.1.208 Problem 211

Internal problem ID [9380]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 211
Date solved : `Monday, January 27, 2025 at 06:02:07 PM`
CAS classification : `[_Laguerre]`

Solve

$$ty'' - (4+t)\,y' + 2y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.253 (sec)

Writing the ode as

$$ty'' + (-4-t)\,y' + 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= t \\ B &= -4-t \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(t) = ye^{\int \frac{B}{2A}\,dt}$$

Then (2) becomes

$$z''(t) = rz(t) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} \tag{5}$$
$$= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{t^2+24}{4t^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= t^2+24 \\ t &= 4t^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(t) = \left(\frac{t^2+24}{4t^2}\right) z(t) \tag{7}$$

Equation (7) is now solved. After finding $z(t)$ then y is found using the inverse transformation

$$y = z(t)\, e^{-\int \frac{B}{2A}\, dt}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.398: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4t^2$. There is a pole at $t = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} + \frac{6}{t^2}$$

For the pole at $t = 0$ let b be the coefficient of $\frac{1}{t^2}$ in the partial fractions decomposition of r given above. Therefore $b = 6$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 3 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -2 \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving t^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i t^i \\ &= \sum_{i=0}^{0} a_i t^i \end{aligned} \tag{8}$$

Let a be the coefficient of $t^v = t^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} + \frac{6}{t^2} - \frac{36}{t^4} + \frac{432}{t^6} - \frac{6480}{t^8} + \frac{108864}{t^{10}} - \frac{1959552}{t^{12}} + \frac{36951552}{t^{14}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i t^i \\ &= \frac{1}{2}\end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $t^{v-1} = t^{-1} = \frac{1}{t}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{t}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{t}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{t}$ in r will be the coefficient in R of the term in t of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned}r &= \frac{s}{t} \\ &= \frac{t^2 + 24}{4t^2} \\ &= Q + \frac{R}{4t^2} \\ &= \left(\frac{1}{4}\right) + \left(\frac{6}{t^2}\right) \\ &= \frac{1}{4} + \frac{6}{t^2}\end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term t in the remainder R is 0. Dividing this by leading coefficient in t which is 4 gives 0. Now b can be found.

$$\begin{aligned}b &= (0) - (0) \\ &= 0\end{aligned}$$

Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= \frac{1}{2} \\ \alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{0}{\frac{1}{2}} - 0\right) &&= 0 \\ \alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{0}{\frac{1}{2}} - 0\right) &&= 0\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{t^2 + 24}{4t^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	3	-2

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	0	0

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 0$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\ &= 0 - (-2) \\ &= 2 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{t-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{t-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= -\frac{2}{t} + (-)\left(\frac{1}{2}\right) \\ &= -\frac{2}{t} - \frac{1}{2} \\ &= -\frac{4+t}{2t} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(t)$ of degree $d = 2$ to solve the ode. The polynomial $p(t)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(t) = t^2 + a_1 t + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (2) + 2\left(-\frac{2}{t} - \frac{1}{2}\right)(2t + a_1) + \left(\left(\frac{2}{t^2}\right) + \left(-\frac{2}{t} - \frac{1}{2}\right)^2 - \left(\frac{t^2+24}{4t^2}\right)\right) &= 0 \\ \frac{(a_1 - 6)\,t + 2a_0 - 4a_1}{t} &= 0 \end{aligned}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 12, a_1 = 6\}$$

Substituting these coefficients in $p(t)$ in eq. (2A) results in

$$p(t) = t^2 + 6t + 12$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(t) &= p e^{\int \omega \, dt} \\ &= \left(t^2+6t+12\right) e^{\int \left(-\frac{2}{t}-\frac{1}{2}\right)dt} \\ &= \left(t^2+6t+12\right) e^{-\frac{t}{2}-2\ln(t)} \\ &= \frac{\left(t^2+6t+12\right) e^{-\frac{t}{2}}}{t^2} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dt} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-4-t}{t}\, dt} \\ &= z_1 e^{\frac{t}{2}+2\ln(t)} \\ &= z_1 \left(t^2 e^{\frac{t}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = t^2+6t+12$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dt}}{y_1^2}\, dt$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-4-t}{t}\, dt}}{\left(y_1\right)^2}\, dt \\ &= y_1 \int \frac{e^{t+4\ln(t)}}{\left(y_1\right)^2}\, dt \\ &= y_1 \left(\frac{\left(t^2-6t+12\right) e^{t+4\ln(t)}}{\left(t^2+6t+12\right) t^4}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(t^2+6t+12\right) + c_2 \left(t^2+6t+12\left(\frac{\left(t^2-6t+12\right) e^{t+4\ln(t)}}{\left(t^2+6t+12\right) t^4}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$\left(\frac{d^2}{dt^2}y(t)\right) t - (t+4)\left(\frac{d}{dt}y(t)\right) + 2y(t) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dt^2}y(t)$

- Isolate 2nd derivative

  $\frac{d^2}{dt^2}y(t) = -\frac{2y(t)}{t} + \frac{(t+4)\left(\frac{d}{dt}y(t)\right)}{t}$

- Group terms with $y(t)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

$\frac{d^2}{dt^2}y(t) - \frac{(t+4)\left(\frac{d}{dt}y(t)\right)}{t} + \frac{2y(t)}{t} = 0$

- ☐ Check to see if $t_0 = 0$ is a regular singular point
  - ◦ Define functions
    $\left[P_2(t) = -\frac{t+4}{t}, P_3(t) = \frac{2}{t}\right]$
  - ◦ $t \cdot P_2(t)$ is analytic at $t = 0$
    $\left(t \cdot P_2(t)\right)\Big|_{t=0} = -4$
  - ◦ $t^2 \cdot P_3(t)$ is analytic at $t = 0$
    $\left(t^2 \cdot P_3(t)\right)\Big|_{t=0} = 0$
  - ◦ $t = 0$is a regular singular point
    Check to see if $t_0 = 0$ is a regular singular point
    $t_0 = 0$
- • Multiply by denominators
  $\left(\frac{d^2}{dt^2}y(t)\right)t + (-t-4)\left(\frac{d}{dt}y(t)\right) + 2y(t) = 0$
- • Assume series solution for $y(t)$
  $y(t) = \sum_{k=0}^{\infty} a_k t^{k+r}$
- ☐ Rewrite ODE with series expansions
  - ◦ Convert $t^m \cdot \left(\frac{d}{dt}y(t)\right)$ to series expansion for $m = 0..1$
    $t^m \cdot \left(\frac{d}{dt}y(t)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, t^{k+r-1+m}$
  - ◦ Shift index using $k- >k+1-m$
    $t^m \cdot \left(\frac{d}{dt}y(t)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, t^{k+r}$
  - ◦ Convert $t \cdot \left(\frac{d^2}{dt^2}y(t)\right)$ to series expansion
    $t \cdot \left(\frac{d^2}{dt^2}y(t)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, t^{k+r-1}$
  - ◦ Shift index using $k- >k+1$
    $t \cdot \left(\frac{d^2}{dt^2}y(t)\right) = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)(k+r)\, t^{k+r}$
    Rewrite ODE with series expansions
    $a_0 r(-5+r)\, t^{-1+r} + \left(\sum_{k=0}^{\infty} \left(a_{k+1}(k+1+r)(k-4+r) - a_k(k+r-2)\right) t^{k+r}\right) = 0$
- • $a_0$cannot be 0 by assumption, giving the indicial equation
  $r(-5+r) = 0$
- • Values of r that satisfy the indicial equation
  $r \in \{0, 5\}$
- • Each term in the series must be 0, giving the recursion relation
  $a_{k+1}(k+1+r)(k-4+r) - a_k(k+r-2) = 0$
- • Recursion relation that defines series solution to ODE
  $a_{k+1} = \frac{a_k(k+r-2)}{(k+1+r)(k-4+r)}$
- • Recursion relation for $r = 0$; series terminates at $k = 2$
  $a_{k+1} = \frac{a_k(k-2)}{(k+1)(k-4)}$
- • Apply recursion relation for $k = 0$
  $a_1 = \frac{a_0}{2}$
- • Apply recursion relation for $k = 1$

$a_2 = \frac{a_1}{6}$

- Express in terms of a_0

  $a_2 = \frac{a_0}{12}$

- Terminating series solution of the ODE for $r = 0$. Use reduction of order to find the second li

  $y(t) = a_0 \cdot \left(1 + \frac{1}{2}t + \frac{1}{12}t^2\right)$

- Recursion relation for $r = 5$

  $a_{k+1} = \frac{a_k(k+3)}{(k+6)(k+1)}$

- Solution for $r = 5$

  $\left[y(t) = \sum_{k=0}^{\infty} a_k t^{k+5}, a_{k+1} = \frac{a_k(k+3)}{(k+6)(k+1)}\right]$

- Combine solutions and rename parameters

  $\left[y(t) = a_0 \cdot \left(1 + \frac{1}{2}t + \frac{1}{12}t^2\right) + \left(\sum_{k=0}^{\infty} b_k t^{5+k}\right), b_{k+1} = \frac{b_k(k+3)}{(k+6)(k+1)}\right]$

Solve

$$t^2y'' + \left(t^2 - 3t\right) y' + 3y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.247 (sec)

Writing the ode as

$$t^2y'' + \left(t^2 - 3t\right) y' + 3y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= t^2 \\ B &= t^2 - 3t \\ C &= 3 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(t) = ye^{\int \frac{B}{2A}\, dt}$$

Then (2) becomes

$$z''(t) = rz(t) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{t^2 - 6t + 3}{4t^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= t^2 - 6t + 3 \\ t &= 4t^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(t) = \left(\frac{t^2 - 6t + 3}{4t^2}\right) z(t) \tag{7}$$

Equation (7) is now solved. After finding $z(t)$ then y is found using the inverse transformation

$$y = z(t)\, e^{-\int \frac{B}{2A}\, dt}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.400: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4t^2$. There is a pole at $t = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} + \frac{3}{4t^2} - \frac{3}{2t}$$

For the pole at $t = 0$ let b be the coefficient of $\frac{1}{t^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving t^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i t^i \\ &= \sum_{i=0}^{0} a_i t^i \end{aligned} \tag{8}$$

Let a be the coefficient of $t^v = t^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} - \frac{3}{2t} - \frac{3}{2t^2} - \frac{9}{2t^3} - \frac{63}{4t^4} - \frac{243}{4t^5} - \frac{999}{4t^6} - \frac{4293}{4t^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i t^i \\ &= \frac{1}{2}\end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $t^{v-1} = t^{-1} = \frac{1}{t}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{t}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{t}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{t}$ in r will be the coefficient in R of the term in t of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned}r &= \frac{s}{t} \\ &= \frac{t^2 - 6t + 3}{4t^2} \\ &= Q + \frac{R}{4t^2} \\ &= \left(\frac{1}{4}\right) + \left(\frac{-6t + 3}{4t^2}\right) \\ &= \frac{1}{4} + \frac{-6t + 3}{4t^2}\end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term t in the remainder R is -6. Dividing this by leading coefficient in t which is 4 gives $-\frac{3}{2}$. Now b can be found.

$$\begin{aligned}b &= \left(-\frac{3}{2}\right) - (0) \\ &= -\frac{3}{2}\end{aligned}$$

Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= \frac{1}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{3}{2}}{\frac{1}{2}} - 0\right) &&= -\frac{3}{2} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{3}{2}}{\frac{1}{2}} - 0\right) &&= \frac{3}{2}\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{t^2 - 6t + 3}{4t^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	$-\frac{3}{2}$	$\frac{3}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{3}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^+\right) \\ &= \frac{3}{2} - \left(\frac{3}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{t-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{t-c_1}\right) + (-)[\sqrt{r}]_\infty \\ &= \frac{3}{2t} + (-)\left(\frac{1}{2}\right) \\ &= \frac{3}{2t} - \frac{1}{2} \\ &= -\frac{t-3}{2t} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(t)$ of degree $d = 0$ to solve the ode. The polynomial $p(t)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}$$

Let

$$p(t) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(\frac{3}{2t} - \frac{1}{2}\right)(0) + \left(\left(-\frac{3}{2t^2}\right) + \left(\frac{3}{2t} - \frac{1}{2}\right)^2 - \left(\frac{t^2-6t+3}{4t^2}\right)\right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(t) &= p e^{\int \omega\, dt} \\ &= e^{\int \left(\frac{3}{2t} - \frac{1}{2}\right) dt} \\ &= t^{3/2} e^{-\frac{t}{2}} \end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dt} \\
&= z_1 e^{-\int \frac{1}{2}\frac{t^2-3t}{t^2}\,dt} \\
&= z_1 e^{-\frac{t}{2}+\frac{3\ln(t)}{2}} \\
&= z_1\left(t^{3/2}\mathrm{e}^{-\frac{t}{2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = t^3\mathrm{e}^{-t}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dt}}{y_1^2}\,dt
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{t^2-3t}{t^2}\,dt}}{(y_1)^2}\,dt \\
&= y_1 \int \frac{e^{-t+3\ln(t)}}{(y_1)^2}\,dt \\
&= y_1\left(-\frac{\mathrm{e}^t}{2t^2}-\frac{\mathrm{e}^t}{2t}-\frac{\mathrm{Ei}_1(-t)}{2}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1y_1 + c_2y_2 \\
&= c_1\left(t^3\mathrm{e}^{-t}\right) + c_2\left(t^3\mathrm{e}^{-t}\left(-\frac{\mathrm{e}^t}{2t^2}-\frac{\mathrm{e}^t}{2t}-\frac{\mathrm{Ei}_1(-t)}{2}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$\left(\frac{d^2}{dt^2}y(t)\right)t^2 + (t^2-3t)\left(\frac{d}{dt}y(t)\right) + 3y(t) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dt^2}y(t)$

- Isolate 2nd derivative

  $\frac{d^2}{dt^2}y(t) = -\frac{3y(t)}{t^2} - \frac{(-3+t)\left(\frac{d}{dt}y(t)\right)}{t}$

- Group terms with $y(t)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d^2}{dt^2}y(t) + \frac{(-3+t)\left(\frac{d}{dt}y(t)\right)}{t} + \frac{3y(t)}{t^2} = 0$

☐ Check to see if $t_0 = 0$ is a regular singular point

- ○ Define functions

  $\left[P_2(t) = \frac{-3+t}{t}, P_3(t) = \frac{3}{t^2}\right]$

- ○ $t \cdot P_2(t)$ is analytic at $t = 0$

$$\left(t \cdot P_2(t)\right)\bigg|_{t=0} = -3$$

- ∘ $t^2 \cdot P_3(t)$ is analytic at $t = 0$

$$\left(t^2 \cdot P_3(t)\right)\bigg|_{t=0} = 3$$

- ∘ $t = 0$is a regular singular point

Check to see if $t_0 = 0$ is a regular singular point

$t_0 = 0$

- Multiply by denominators

$$\left(\frac{d^2}{dt^2}y(t)\right)t^2 + (-3+t)\,t\left(\frac{d}{dt}y(t)\right) + 3y(t) = 0$$

- Assume series solution for $y(t)$

$$y(t) = \sum_{k=0}^{\infty} a_k t^{k+r}$$

□ Rewrite ODE with series expansions

- ∘ Convert $t^m \cdot \left(\frac{d}{dt}y(t)\right)$ to series expansion for $m = 1..2$

$$t^m \cdot \left(\frac{d}{dt}y(t)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,t^{k+r-1+m}$$

- ∘ Shift index using $k- >k+1-m$

$$t^m \cdot \left(\frac{d}{dt}y(t)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,t^{k+r}$$

- ∘ Convert $t^2 \cdot \left(\frac{d^2}{dt^2}y(t)\right)$ to series expansion

$$t^2 \cdot \left(\frac{d^2}{dt^2}y(t)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,t^{k+r}$$

Rewrite ODE with series expansions

$$a_0(-1+r)\,(-3+r)\,t^r + \left(\sum_{k=1}^{\infty} \left(a_k(k+r-1)\,(k+r-3) + a_{k-1}(k+r-1)\right)t^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$(-1+r)\,(-3+r) = 0$

- Values of r that satisfy the indicial equation

$r \in \{1, 3\}$

- Each term in the series must be 0, giving the recursion relation

$(k+r-1)\,(a_k(k+r-3) + a_{k-1}) = 0$

- Shift index using $k- >k+1$

$(k+r)\,(a_{k+1}(k-2+r) + a_k) = 0$

- Recursion relation that defines series solution to ODE

$a_{k+1} = -\frac{a_k}{k-2+r}$

- Recursion relation for $r = 1$

$a_{k+1} = -\frac{a_k}{k-1}$

- Series not valid for $r = 1$, division by 0 in the recursion relation at $k = 1$

$a_{k+1} = -\frac{a_k}{k-1}$

- Recursion relation for $r = 3$

$a_{k+1} = -\frac{a_k}{k+1}$

- Solution for $r = 3$

$$\left[y(t) = \sum_{k=0}^{\infty} a_k t^{k+3}, a_{k+1} = -\frac{a_k}{k+1}\right]$$

2.1.210 Problem 213

Internal problem ID [9382]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 213
Date solved : `Monday, January 27, 2025 at 06:02:08 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$ty'' + ty' + 2y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.226 (sec)

Writing the ode as

$$ty'' + ty' + 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= t \\ B &= t \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(t) = ye^{\int \frac{B}{2A}\, dt}$$

Then (2) becomes

$$z''(t) = rz(t) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{t-8}{4t} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= t - 8 \\ t &= 4t \end{aligned}$$

Therefore eq. (4) becomes

$$z''(t) = \left(\frac{t-8}{4t}\right) z(t) \tag{7}$$

Equation (7) is now solved. After finding $z(t)$ then y is found using the inverse transformation

$$y = z(t)\, e^{-\int \frac{B}{2A}\, dt}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.402: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 1 - 1 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4t$. There is a pole at $t = 0$ of order 1. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 1. For the pole at $t = 0$ of order 1 then

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= 1 \\ \alpha_c^- &= 1 \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving t^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i t^i \\ &= \sum_{i=0}^{0} a_i t^i \end{aligned} \tag{8}$$

Let a be the coefficient of $t^v = t^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} - \frac{2}{t} - \frac{4}{t^2} - \frac{16}{t^3} - \frac{80}{t^4} - \frac{448}{t^5} - \frac{2688}{t^6} - \frac{16896}{t^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i t^i \\ &= \frac{1}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $t^{v-1} = t^{-1} = \frac{1}{t}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{t}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{t}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{t}$ in r will be the coefficient in R of the term in t of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{t-8}{4t} \\ &= Q + \frac{R}{4t} \\ &= \left(\frac{1}{4}\right) + \left(-\frac{2}{t}\right) \\ &= \frac{1}{4} - \frac{2}{t} \end{aligned}$$

Since the degree of t is 1, then we see that the coefficient of the term 1 in the remainder R is -8. Dividing this by leading coefficient in t which is 4 gives -2. Now b can be found.

$$\begin{aligned} b &= (-2) - (0) \\ &= -2 \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) = \frac{1}{2}\left(\frac{-2}{\frac{1}{2}} - 0\right) = -2 \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) = \frac{1}{2}\left(-\frac{-2}{\frac{1}{2}} - 0\right) = 2 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{t-8}{4t}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	1	0	0	1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	-2	2

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 2$ then

$$\begin{aligned} d &= \alpha_\infty^- - (\alpha_{c_1}^-) \\ &= 2 - (1) \\ &= 1 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{t-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{t-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{1}{t} + (-)\left(\frac{1}{2}\right) \\ &= \frac{1}{t} - \frac{1}{2} \\ &= \frac{1}{t} - \frac{1}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(t)$ of degree $d = 1$ to solve the ode. The polynomial $p(t)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(t) = t + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(\frac{1}{t} - \frac{1}{2}\right)(1) + \left(\left(-\frac{1}{t^2}\right) + \left(\frac{1}{t} - \frac{1}{2}\right)^2 - \left(\frac{t-8}{4t}\right) \right) &= 0 \\ \frac{2+a_0}{t} &= 0 \end{aligned}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = -2\}$$

Substituting these coefficients in $p(t)$ in eq. (2A) results in

$$p(t) = -2 + t$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(t) &= p e^{\int \omega \, dt} \\ &= (-2+t)\, e^{\int \left(\frac{1}{t} - \frac{1}{2}\right) dt} \\ &= (-2+t)\, e^{-\frac{t}{2} + \ln(t)} \\ &= (-2+t)\, t\, e^{-\frac{t}{2}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dt} \\ &= z_1 e^{-\int \frac{1}{2}\frac{t}{t}\,dt} \\ &= z_1 e^{-\frac{t}{2}} \\ &= z_1\left(\mathrm{e}^{-\frac{t}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-t}(-2+t)\,t$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dt}}{y_1^2}\,dt$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{t}{t}\,dt}}{(y_1)^2}\,dt \\ &= y_1 \int \frac{e^{-t}}{(y_1)^2}\,dt \\ &= y_1\left(-\frac{\mathrm{e}^t(-t+1)}{2(2-t)\,t} - \frac{\mathrm{Ei}_1(-t)}{2}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\mathrm{e}^{-t}(-2+t)\,t\right) + c_2\left(\mathrm{e}^{-t}(-2+t)\,t\left(-\frac{\mathrm{e}^t(-t+1)}{2(2-t)\,t} - \frac{\mathrm{Ei}_1(-t)}{2}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve
$\left(\frac{d^2}{dt^2}y(t)\right)t + t\left(\frac{d}{dt}y(t)\right) + 2y(t) = 0$

- Highest derivative means the order of the ODE is 2
  $\frac{d^2}{dt^2}y(t)$
- Isolate 2nd derivative
  $\frac{d^2}{dt^2}y(t) = -\frac{2y(t)}{t} - \frac{d}{dt}y(t)$
- Group terms with $y(t)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin
  $\frac{d^2}{dt^2}y(t) + \frac{d}{dt}y(t) + \frac{2y(t)}{t} = 0$

□ Check to see if $t_0 = 0$ is a regular singular point
  - Define functions
    $\left[P_2(t) = 1, P_3(t) = \frac{2}{t}\right]$
  - $t \cdot P_2(t)$ is analytic at $t = 0$
    $\left.(t \cdot P_2(t))\right|_{t=0} = 0$

- $t^2 \cdot P_3(t)$ is analytic at $t = 0$

  $\left(t^2 \cdot P_3(t)\right)\Big|_{t=0} = 0$

- $t = 0$is a regular singular point

  Check to see if $t_0 = 0$ is a regular singular point

  $t_0 = 0$

- Multiply by denominators

  $\left(\frac{d^2}{dt^2}y(t)\right)t + t\left(\frac{d}{dt}y(t)\right) + 2y(t) = 0$

- Assume series solution for $y(t)$

  $y(t) = \sum_{k=0}^{\infty} a_k t^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $t \cdot \left(\frac{d}{dt}y(t)\right)$ to series expansion

  $t \cdot \left(\frac{d}{dt}y(t)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, t^{k+r}$

- Convert $t \cdot \left(\frac{d^2}{dt^2}y(t)\right)$ to series expansion

  $t \cdot \left(\frac{d^2}{dt^2}y(t)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, t^{k+r-1}$

- Shift index using $k- >k+1$

  $t \cdot \left(\frac{d^2}{dt^2}y(t)\right) = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\,(k+r)\, t^{k+r}$

  Rewrite ODE with series expansions

  $a_0 r(-1+r)\, t^{-1+r} + \left(\sum_{k=0}^{\infty} \left(a_{k+1}(k+1+r)\,(k+r) + a_k(k+r+2)\right) t^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r(-1+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{0, 1\}$

- Each term in the series must be 0, giving the recursion relation

  $a_{k+1}(k+1+r)\,(k+r) + a_k(k+r+2) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+1} = -\frac{a_k(k+r+2)}{(k+1+r)(k+r)}$

- Recursion relation for $r = 0$

  $a_{k+1} = -\frac{a_k(k+2)}{(k+1)k}$

- Solution for $r = 0$

  $\left[y(t) = \sum_{k=0}^{\infty} a_k t^k, a_{k+1} = -\frac{a_k(k+2)}{(k+1)k}\right]$

- Recursion relation for $r = 1$

  $a_{k+1} = -\frac{a_k(k+3)}{(k+2)(k+1)}$

- Solution for $r = 1$

  $\left[y(t) = \sum_{k=0}^{\infty} a_k t^{k+1}, a_{k+1} = -\frac{a_k(k+3)}{(k+2)(k+1)}\right]$

- Combine solutions and rename parameters

  $\left[y(t) = \left(\sum_{k=0}^{\infty} a_k t^k\right) + \left(\sum_{k=0}^{\infty} b_k t^{k+1}\right), a_{k+1} = -\frac{a_k(k+2)}{(k+1)k}, b_{k+1} = -\frac{b_k(k+3)}{(k+2)(k+1)}\right]$

2.1.211 Problem 214

Internal problem ID [9383]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 214
Date solved : `Monday, January 27, 2025 at 06:02:09 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$ty'' + \left(-t^2 + 1\right) y' + 4ty = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.657 (sec)

Writing the ode as

$$ty'' + \left(-t^2 + 1\right) y' + 4ty = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= t \\ B &= -t^2 + 1 \\ C &= 4t \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(t) = ye^{\int \frac{B}{2A}\, dt}$$

Then (2) becomes

$$z''(t) = rz(t) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{t^4 - 20t^2 - 1}{4t^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= t^4 - 20t^2 - 1 \\ t &= 4t^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(t) = \left(\frac{t^4 - 20t^2 - 1}{4t^2}\right) z(t) \tag{7}$$

Equation (7) is now solved. After finding $z(t)$ then y is found using the inverse transformation

$$y = z(t)\, e^{-\int \frac{B}{2A}\, dt}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.404: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 4 \\ &= -2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4t^2$. There is a pole at $t = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{t^2}{4} - 5 - \frac{1}{4t^2}$$

For the pole at $t = 0$ let b be the coefficient of $\frac{1}{t^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving t^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i t^i \\ &= \sum_{i=0}^{1} a_i t^i \end{aligned} \tag{8}$$

Let a be the coefficient of $t^v = t^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{t}{2} - \frac{5}{t} - \frac{101}{4t^3} - \frac{505}{2t^5} - \frac{50601}{16t^7} - \frac{355015}{8t^9} - \frac{21351501}{32t^{11}} - \frac{168167525}{16t^{13}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i t^i \\ &= \frac{t}{2}\end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $t^{v-1} = t^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{t^2}{4}$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned}r &= \frac{s}{t} \\ &= \frac{t^4 - 20t^2 - 1}{4t^2} \\ &= Q + \frac{R}{4t^2} \\ &= \left(\frac{t^2}{4} - 5\right) + \left(-\frac{1}{4t^2}\right) \\ &= \frac{t^2}{4} - 5 - \frac{1}{4t^2}\end{aligned}$$

We see that the coefficient of the term t in the quotient is -5. Now b can be found.

$$\begin{aligned}b &= (-5) - (0) \\ &= -5\end{aligned}$$

Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= \frac{t}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-5}{\frac{1}{2}} - 1\right) &= -\frac{11}{2} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-5}{\frac{1}{2}} - 1\right) &= \frac{9}{2}\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{t^4 - 20t^2 - 1}{4t^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-2	$\frac{t}{2}$	$-\frac{11}{2}$	$\frac{9}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{9}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^+\right) \\ &= \frac{9}{2} - \left(\frac{1}{2}\right) \\ &= 4 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{t-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{t-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{1}{2t} + (-)\left(\frac{t}{2}\right) \\ &= \frac{1}{2t} - \frac{t}{2} \\ &= \frac{1}{2t} - \frac{t}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(t)$ of degree $d = 4$ to solve the ode. The polynomial $p(t)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(t) = t^4 + a_3 t^3 + a_2 t^2 + a_1 t + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\left(12t^2 + 6ta_3 + 2a_2\right) + 2\left(\frac{1}{2t} - \frac{t}{2}\right)\left(4t^3 + 3a_3t^2 + 2a_2t + a_1\right) + \left(\left(-\frac{1}{2t^2} - \frac{1}{2}\right) + \left(\frac{1}{2t} - \frac{t}{2}\right)^2 - \left(\frac{t^4 - 20t}{4t^2}\right.\right.$$

$$\frac{t^4 a_3 + 2(8+a_2)\,t^3 + 3(a_1 + 3a_3)\,t^2 + 4(a_0 + a_2)\,t}{t}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 8, a_1 = 0, a_2 = -8, a_3 = 0\}$$

Substituting these coefficients in $p(t)$ in eq. (2A) results in

$$p(t) = t^4 - 8t^2 + 8$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(t) &= p e^{\int \omega \, dt} \\
&= \left(t^4 - 8t^2 + 8\right) \mathrm{e}^{\int \left(\frac{1}{2t} - \frac{t}{2}\right) dt} \\
&= \left(t^4 - 8t^2 + 8\right) \mathrm{e}^{-\frac{t^2}{4} + \frac{\ln(t)}{2}} \\
&= \left(t^4 - 8t^2 + 8\right) \sqrt{t}\, \mathrm{e}^{-\frac{t^2}{4}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dt} \\
&= z_1 e^{-\int \frac{1}{2} \frac{-t^2+1}{t} \, dt} \\
&= z_1 e^{\frac{t^2}{4} - \frac{\ln(t)}{2}} \\
&= z_1 \left(\frac{\mathrm{e}^{\frac{t^2}{4}}}{\sqrt{t}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = t^4 - 8t^2 + 8$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dt}}{y_1^2} \, dt$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-t^2+1}{t} \, dt}}{(y_1)^2} \, dt \\
&= y_1 \int \frac{e^{\frac{t^2}{2} - \ln(t)}}{(y_1)^2} \, dt \\
&= y_1 \left(\int \frac{\mathrm{e}^{\frac{t^2}{2} - \ln(t)}}{\left(t^4 - 8t^2 + 8\right)^2} dt\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(t^4 - 8t^2 + 8\right) + c_2 \left(t^4 - 8t^2 + 8 \left(\int \frac{\mathrm{e}^{\frac{t^2}{2} - \ln(t)}}{\left(t^4 - 8t^2 + 8\right)^2} dt\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$\left(\frac{d^2}{dt^2}y(t)\right)t+(-t^2+1)\left(\frac{d}{dt}y(t)\right)+4ty(t)=0$

- Highest derivative means the order of the ODE is 2

$\frac{d^2}{dt^2}y(t)$

- Isolate 2nd derivative

$\frac{d^2}{dt^2}y(t)=-4y(t)+\frac{(t^2-1)\left(\frac{d}{dt}y(t)\right)}{t}$

- Group terms with $y(t)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

$\frac{d^2}{dt^2}y(t)-\frac{(t^2-1)\left(\frac{d}{dt}y(t)\right)}{t}+4y(t)=0$

□ Check to see if $t_0=0$ is a regular singular point

- Define functions

$\left[P_2(t)=-\frac{t^2-1}{t},P_3(t)=4\right]$

- $t\cdot P_2(t)$ is analytic at $t=0$

$(t\cdot P_2(t))\bigg|_{t=0}=1$

- $t^2\cdot P_3(t)$ is analytic at $t=0$

$(t^2\cdot P_3(t))\bigg|_{t=0}=0$

- $t=0$is a regular singular point

Check to see if $t_0=0$ is a regular singular point

$t_0=0$

- Multiply by denominators

$\left(\frac{d^2}{dt^2}y(t)\right)t+(-t^2+1)\left(\frac{d}{dt}y(t)\right)+4ty(t)=0$

- Assume series solution for $y(t)$

$y(t)=\sum_{k=0}^{\infty}a_k t^{k+r}$

□ Rewrite ODE with series expansions

- Convert $t\cdot y(t)$ to series expansion

$t\cdot y(t)=\sum_{k=0}^{\infty}a_k t^{k+r+1}$

- Shift index using $k->k-1$

$t\cdot y(t)=\sum_{k=1}^{\infty}a_{k-1}t^{k+r}$

- Convert $t^m\cdot\left(\frac{d}{dt}y(t)\right)$ to series expansion for $m=0..2$

$t^m\cdot\left(\frac{d}{dt}y(t)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,t^{k+r-1+m}$

- Shift index using $k->k+1-m$

$t^m\cdot\left(\frac{d}{dt}y(t)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,t^{k+r}$

- Convert $t\cdot\left(\frac{d^2}{dt^2}y(t)\right)$ to series expansion

$t\cdot\left(\frac{d^2}{dt^2}y(t)\right)=\sum_{k=0}^{\infty}a_k(k+r)(k+r-1)\,t^{k+r-1}$

- Shift index using $k->k+1$

$t\cdot\left(\frac{d^2}{dt^2}y(t)\right)=\sum_{k=-1}^{\infty}a_{k+1}(k+r+1)(k+r)\,t^{k+r}$

Rewrite ODE with series expansions

$$a_0 r^2 t^{-1+r} + a_1 (1+r)^2 t^r + \left(\sum_{k=1}^{\infty} \left(a_{k+1}(k+r+1)^2 - a_{k-1}(k-5+r)\right) t^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $r^2 = 0$
- Values of r that satisfy the indicial equation
  $r = 0$
- Each term must be 0
  $a_1 (1+r)^2 = 0$
- Each term in the series must be 0, giving the recursion relation
  $a_{k+1}(k+1)^2 - a_{k-1}(k-5) = 0$
- Shift index using $k- >k+1$
  $a_{k+2}(k+2)^2 - a_k(k-4) = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+2} = \frac{a_k(k-4)}{(k+2)^2}$
- Recursion relation for $r = 0$; series terminates at $k = 4$
  $a_{k+2} = \frac{a_k(k-4)}{(k+2)^2}$
- Solution for $r = 0$
  $\left[y(t) = \sum_{k=0}^{\infty} a_k t^k, a_{k+2} = \frac{a_k(k-4)}{(k+2)^2}, a_1 = 0\right]$

Date solved : `Monday, January 27, 2025 at 06:02:10 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$t^2y'' - t(1+t)\,y' + y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.225 (sec)

Writing the ode as

$$t^2y'' + \left(-t^2 - t\right) y' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= t^2 \\ B &= -t^2 - t \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(t) = ye^{\int \frac{B}{2A}\,dt}$$

Then (2) becomes

$$z''(t) = rz(t) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{t^2 + 2t - 1}{4t^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= t^2 + 2t - 1 \\ t &= 4t^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(t) = \left(\frac{t^2 + 2t - 1}{4t^2}\right) z(t) \tag{7}$$

Equation (7) is now solved. After finding $z(t)$ then y is found using the inverse transformation

$$y = z(t)\, e^{-\int \frac{B}{2A}\, dt}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.406: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4t^2$. There is a pole at $t = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} - \frac{1}{4t^2} + \frac{1}{2t}$$

For the pole at $t = 0$ let b be the coefficient of $\frac{1}{t^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving t^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i t^i \\ &= \sum_{i=0}^{0} a_i t^i \end{aligned} \tag{8}$$

Let a be the coefficient of $t^v = t^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} + \frac{1}{2t} - \frac{1}{2t^2} + \frac{1}{2t^3} - \frac{3}{4t^4} + \frac{5}{4t^5} - \frac{9}{4t^6} + \frac{17}{4t^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i t^i \\ &= \frac{1}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $t^{v-1} = t^{-1} = \frac{1}{t}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{t}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{t}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{t}$ in r will be the coefficient in R of the term in t of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{t^2 + 2t - 1}{4t^2} \\ &= Q + \frac{R}{4t^2} \\ &= \left(\frac{1}{4}\right) + \left(\frac{2t - 1}{4t^2}\right) \\ &= \frac{1}{4} + \frac{2t - 1}{4t^2} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term t in the remainder R is 2. Dividing this by leading coefficient in t which is 4 gives $\frac{1}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(\frac{1}{2}\right) - (0) \\ &= \frac{1}{2} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{2} \\ \alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{\frac{1}{2}}{\frac{1}{2}} - 0\right) &&= \frac{1}{2} \\ \alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{\frac{1}{2}}{\frac{1}{2}} - 0\right) &&= -\frac{1}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{t^2 + 2t - 1}{4t^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	$\frac{1}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^+ - (\alpha_{c_1}^+) \\ &= \frac{1}{2} - \left(\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{t-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{t-c_1} \right) + (+)[\sqrt{r}]_\infty \\ &= \frac{1}{2t} + \left(\frac{1}{2}\right) \\ &= \frac{1}{2} + \frac{1}{2t} \\ &= \frac{1+t}{2t} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(t)$ of degree $d = 0$ to solve the ode. The polynomial $p(t)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(t) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(\frac{1}{2} + \frac{1}{2t}\right)(0) + \left(\left(-\frac{1}{2t^2}\right) + \left(\frac{1}{2} + \frac{1}{2t}\right)^2 - \left(\frac{t^2+2t-1}{4t^2}\right)\right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(t) &= p e^{\int \omega\, dt} \\ &= \mathrm{e}^{\int \left(\frac{1}{2} + \frac{1}{2t}\right) dt} \\ &= \sqrt{t}\, \mathrm{e}^{\frac{t}{2}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dt} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-t^2-t}{t^2}\,dt} \\
&= z_1 e^{\frac{t}{2}+\frac{\ln(t)}{2}} \\
&= z_1\left(\sqrt{t}\,\mathrm{e}^{\frac{t}{2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = t\,\mathrm{e}^t$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dt}}{y_1^2}\,dt$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-t^2-t}{t^2}\,dt}}{(y_1)^2}\,dt \\
&= y_1 \int \frac{e^{t+\ln(t)}}{(y_1)^2}\,dt \\
&= y_1(-\operatorname{Ei}_1(t))
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(t\,\mathrm{e}^t\right) + c_2\left(t\,\mathrm{e}^t(-\operatorname{Ei}_1(t))\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve
$\left(\frac{d^2}{dt^2}y(t)\right)t^2 - t(t+1)\left(\frac{d}{dt}y(t)\right) + y(t) = 0$

- Highest derivative means the order of the ODE is 2
  $\frac{d^2}{dt^2}y(t)$
- Isolate 2nd derivative
  $\frac{d^2}{dt^2}y(t) = \frac{(t+1)\left(\frac{d}{dt}y(t)\right)}{t} - \frac{y(t)}{t^2}$
- Group terms with $y(t)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear
  $\frac{d^2}{dt^2}y(t) + \frac{y(t)}{t^2} - \frac{(t+1)\left(\frac{d}{dt}y(t)\right)}{t} = 0$

□ Check to see if $t_0 = 0$ is a regular singular point
  - Define functions
    $\left[P_2(t) = -\frac{t+1}{t}, P_3(t) = \frac{1}{t^2}\right]$
  - $t \cdot P_2(t)$ is analytic at $t = 0$
    $\left(t \cdot P_2(t)\right)\Big|_{t=0} = -1$
  - $t^2 \cdot P_3(t)$ is analytic at $t = 0$

$$\left(t^2 \cdot P_3(t)\right)\Big|_{t=0} = 1$$

- ◦ $t = 0$is a regular singular point
  Check to see if $t_0 = 0$ is a regular singular point
  $t_0 = 0$
- Multiply by denominators
  $\left(\frac{d^2}{dt^2}y(t)\right)t^2 - t(t+1)\left(\frac{d}{dt}y(t)\right) + y(t) = 0$
- Assume series solution for $y(t)$
  $y(t) = \sum_{k=0}^{\infty} a_k t^{k+r}$
- □ Rewrite ODE with series expansions
  - ◦ Convert $t^m \cdot \left(\frac{d}{dt}y(t)\right)$ to series expansion for $m = 1..2$
    $t^m \cdot \left(\frac{d}{dt}y(t)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, t^{k+r-1+m}$
  - ◦ Shift index using $k- >k+1-m$
    $t^m \cdot \left(\frac{d}{dt}y(t)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, t^{k+r}$
  - ◦ Convert $t^2 \cdot \left(\frac{d^2}{dt^2}y(t)\right)$ to series expansion
    $t^2 \cdot \left(\frac{d^2}{dt^2}y(t)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, t^{k+r}$

  Rewrite ODE with series expansions
  $a_0(-1+r)^2 t^r + \left(\sum_{k=1}^{\infty} \left(a_k(k+r-1)^2 - a_{k-1}(k+r-1)\right) t^{k+r}\right) = 0$
- $a_0$cannot be 0 by assumption, giving the indicial equation
  $(-1+r)^2 = 0$
- Values of r that satisfy the indicial equation
  $r = 1$
- Each term in the series must be 0, giving the recursion relation
  $(k+r-1)\left(a_k(k+r-1) - a_{k-1}\right) = 0$
- Shift index using $k- >k+1$
  $(k+r)\left(a_{k+1}(k+r) - a_k\right) = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+1} = \frac{a_k}{k+r}$
- Recursion relation for $r = 1$
  $a_{k+1} = \frac{a_k}{k+1}$
- Solution for $r = 1$
  $\left[y(t) = \sum_{k=0}^{\infty} a_k t^{k+1}, a_{k+1} = \frac{a_k}{k+1}\right]$

2.1.213 Problem 216

Internal problem ID [9385]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 216
Date solved : `Monday, January 27, 2025 at 06:02:10 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$y'' + 4xy' + \left(4x^2 + 6\right) y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.162 (sec)

Writing the ode as

$$y'' + 4xy' + \left(4x^2 + 6\right) y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 4x \\ C &= 4x^2 + 6 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-4}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -4 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -4z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.408: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -4$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(2x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{4x}{1}\, dx} \\ &= z_1 e^{-x^2} \\ &= z_1 \left(\mathrm{e}^{-x^2}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-x^2} \cos(2x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{4x}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{-2x^2}}{(y_1)^2}\,dx \\ &= y_1 \left(\frac{\tan(2x)}{2}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\mathrm{e}^{-x^2}\cos(2x)\right) + c_2 \left(\mathrm{e}^{-x^2}\cos(2x)\left(\frac{\tan(2x)}{2}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$\frac{d^2}{dx^2}y(x) + 4x\left(\frac{d}{dx}y(x)\right) + (4x^2+6)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite ODE with series expansions

  ◦ Convert $x^m \cdot y(x)$ to series expansion for $m = 0..2$

  $x^m \cdot y(x) = \sum_{k=\max(0,-m)}^{\infty} a_k x^{k+m}$

  ◦ Shift index using $k->k-m$

  $x^m \cdot y(x) = \sum_{k=\max(0,-m)+m}^{\infty} a_{k-m} x^k$

  ◦ Convert $x \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion

  $x \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k k\, x^k$

  ◦ Convert $\frac{d^2}{dx^2}y(x)$ to series expansion

  $\frac{d^2}{dx^2}y(x) = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$

  ◦ Shift index using $k->k+2$

  $\frac{d^2}{dx^2}y(x) = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$

  Rewrite ODE with series expansions

  $2a_2 + 6a_0 + (6a_3 + 10a_1)\,x + \left(\sum_{k=2}^{\infty} \left(a_{k+2}(k+2)\,(k+1) + 2a_k(2k+3) + 4a_{k-2}\right) x^k\right) = 0$

- The coefficients of each power of x must be 0

  $[2a_2 + 6a_0 = 0, 6a_3 + 10a_1 = 0]$

- Solve for the dependent coefficient(s)

  $\left\{a_2 = -3a_0, a_3 = -\frac{5a_1}{3}\right\}$

- Each term in the series must be 0, giving the recursion relation
  $$(k^2+3k+2)\, a_{k+2}+4a_k k+6a_k+4a_{k-2}=0$$
- Shift index using $k->k+2$
  $$\left((k+2)^2+3k+8\right) a_{k+4}+4a_{k+2}(k+2)+6a_{k+2}+4a_k=0$$
- Recursion relation that defines the series solution to the ODE
  $$\left[y(x)=\sum_{k=0}^{\infty} a_k x^k, a_{k+4}=-\frac{2(2ka_{k+2}+2a_k+7a_{k+2})}{k^2+7k+12}, a_2=-3a_0, a_3=-\frac{5a_1}{3}\right]$$

2.1.214 Problem 217

Internal problem ID [9386]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 217
Date solved : `Monday, January 27, 2025 at 06:02:11 PM`
CAS classification : `[_Gegenbauer]`

Solve

$$\left(-z^2+1\right) y''-3zy'+\lambda y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.474 (sec)

Writing the ode as

$$\left(-z^2+1\right) y''-3zy'+\lambda y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= -z^2+1 \\ B &= -3z \\ C &= \lambda \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(z)=ye^{\int \frac{B}{2A}\,dz}$$

Then (2) becomes

$$z''(z)=rz(z) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{4\lambda\, z^2+3z^2-4\lambda-6}{4\left(z^2-1\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 4\lambda\, z^2+3z^2-4\lambda-6 \\ t &= 4\left(z^2-1\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(z)=\left(\frac{4\lambda\, z^2+3z^2-4\lambda-6}{4\left(z^2-1\right)^2}\right) z(z) \tag{7}$$

Equation (7) is now solved. After finding $z(z)$ then y is found using the inverse transformation

$$y = z(z)\, e^{-\int \frac{B}{2A}\, dz}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.410: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(z^2-1)^2$. There is a pole at $z = 1$ of order 2. There is a pole at $z = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Unable to find solution using case one

Attempting to find a solution using case $n = 2$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{3}{16\,(z-1)^2} + \frac{\frac{9}{16} + \frac{\lambda}{2}}{z-1} - \frac{3}{16\,(z+1)^2} + \frac{-\frac{\lambda}{2} - \frac{9}{16}}{z+1}$$

For the pole at $z = 1$ let b be the coefficient of $\frac{1}{(z-1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} E_c &= \{2, 2 + 2\sqrt{1+4b}, 2 - 2\sqrt{1+4b}\} \\ &= \{1, 2, 3\} \end{aligned}$$

For the pole at $z = -1$ let b be the coefficient of $\frac{1}{(z+1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} E_c &= \{2, 2 + 2\sqrt{1+4b}, 2 - 2\sqrt{1+4b}\} \\ &= \{1, 2, 3\} \end{aligned}$$

Since the order of r at ∞ is 2 then let b be the coefficient of $\frac{1}{z^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{4\lambda\, z^2 + 3z^2 - 4\lambda - 6}{4\left(z^2 - 1\right)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = 1$. Hence

$$\begin{aligned} E_\infty &= \{2, 2 + 2\sqrt{1+4b}, 2 - 2\sqrt{1+4b}\} \\ &= \{2\} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ for case 2 of Kovacic algorithm.

pole c location	pole order	E_c
1	2	$\{1, 2, 3\}$
-1	2	$\{1, 2, 3\}$

Order of r at ∞	E_∞
2	$\{2\}$

Using the family $\{e_1, e_2, \ldots, e_\infty\}$ given by

$$e_1 = 1,\ e_2 = 1,\ e_\infty = 2$$

Gives a non negative integer d (the degree of the polynomial $p(z)$), which is generated using

$$\begin{aligned} d &= \frac{1}{2}\left(e_\infty - \sum_{c\in\Gamma} e_c\right) \\ &= \frac{1}{2}(2 - (1 + (1))) \\ &= 0 \end{aligned}$$

We now form the following rational function

$$\begin{aligned} \theta &= \frac{1}{2}\sum_{c\in\Gamma} \frac{e_c}{z - c} \\ &= \frac{1}{2}\left(\frac{1}{(z - (1))} + \frac{1}{(z - (-1))}\right) \\ &= \frac{1}{2z - 2} + \frac{1}{2z + 2} \end{aligned}$$

Now we search for a monic polynomial $p(z)$ of degree $d = 0$ such that

$$p''' + 3\theta p'' + \left(3\theta^2 + 3\theta' - 4r\right)p' + \left(\theta'' + 3\theta\theta' + \theta^3 - 4r\theta - 2r'\right)p = 0 \tag{1A}$$

Since $d = 0$, then letting

$$p = 1 \tag{2A}$$

Substituting p and θ into Eq. (1A) gives

$$0 = 0$$

And solving for p gives

$$p = 1$$

Now that $p(z)$ is found let

$$\begin{aligned} \phi &= \theta + \frac{p'}{p} \\ &= \frac{1}{2z - 2} + \frac{1}{2z + 2} \end{aligned}$$

Let ω be the solution of

$$\omega^2 - \phi\omega + \left(\frac{1}{2}\phi' + \frac{1}{2}\phi^2 - r\right) = 0$$

Substituting the values for ϕ and r into the above equation gives

$$w^2 - \left(\frac{1}{2z-2} + \frac{1}{2z+2}\right) w + \frac{-4\lambda\, z^2 - 3z^2 + 4\lambda + 4}{4\left(z^2-1\right)^2} = 0$$

Solving for ω gives

$$\omega = \frac{z + 2\sqrt{\left(z^2-1\right)\left(\lambda+1\right)}}{2\left(z-1\right)\left(z+1\right)}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(z) &= e^{\int \omega \, dz} \\ &= e^{\int \frac{z+2\sqrt{\left(z^2-1\right)\left(\lambda+1\right)}}{2(z-1)(z+1)} dz} \\ &= \left(z^2-1\right)^{1/4} \left(\frac{\sqrt{\left(z^2-1\right)\left(\lambda+1\right)}\,\sqrt{\lambda+1} + \lambda z + z}{\sqrt{\lambda+1}}\right)^{\sqrt{\lambda+1}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dz} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-3z}{-z^2+1}\, dz} \\ &= z_1 e^{-\frac{3\ln(z-1)}{4} - \frac{3\ln(z+1)}{4}} \\ &= z_1 \left(\frac{1}{\left(z-1\right)^{3/4}\left(z+1\right)^{3/4}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{\left(z^2-1\right)^{1/4}\left(\sqrt{\lambda+1}\left(z+\sqrt{z^2-1}\right)\right)^{\sqrt{\lambda+1}}}{\left(z-1\right)^{3/4}\left(z+1\right)^{3/4}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dz}}{y_1^2}\, dz$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-3z}{-z^2+1}\, dz}}{\left(y_1\right)^2}\, dz \\ &= y_1 \int \frac{e^{-\frac{3\ln(z-1)}{2} - \frac{3\ln(z+1)}{2}}}{\left(y_1\right)^2}\, dz \\ &= y_1 \left(-\frac{\left(\sqrt{\lambda+1}\left(z+\sqrt{z^2-1}\right)\right)^{-2\sqrt{\lambda+1}}}{2\sqrt{\lambda+1}}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\frac{\left(z^2-1\right)^{1/4}\left(\sqrt{\lambda+1}\left(z+\sqrt{z^2-1}\right)\right)^{\sqrt{\lambda+1}}}{\left(z-1\right)^{3/4}\left(z+1\right)^{3/4}}\right) + c_2 \left(\frac{\left(z^2-1\right)^{1/4}\left(\sqrt{\lambda+1}\left(z+\sqrt{z^2-1}\right)\right)^{\sqrt{\lambda+1}}}{\left(z-1\right)^{3/4}\left(z+1\right)^{3/4}}\left(-\frac{\left(\sqrt{\lambda+\right.}}{}\right.\right. \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve
$(-z^2+1)\left(\frac{d^2}{dz^2}y(z)\right)-3z\left(\frac{d}{dz}y(z)\right)+\lambda y(z)=0$

- Highest derivative means the order of the ODE is 2
$\frac{d^2}{dz^2}y(z)$
- Isolate 2nd derivative
$\frac{d^2}{dz^2}y(z)=\frac{\lambda y(z)}{z^2-1}-\frac{3z\left(\frac{d}{dz}y(z)\right)}{z^2-1}$
- Group terms with $y(z)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin
$\frac{d^2}{dz^2}y(z)+\frac{3z\left(\frac{d}{dz}y(z)\right)}{z^2-1}-\frac{\lambda y(z)}{z^2-1}=0$

☐ Check to see if z_0 is a regular singular point
  - Define functions
  $\left[P_2(z)=\frac{3z}{z^2-1}, P_3(z)=-\frac{\lambda}{z^2-1}\right]$
  - $(z+1)\cdot P_2(z)$ is analytic at $z=-1$
  $\left((z+1)\cdot P_2(z)\right)\Big|_{z=-1}=\frac{3}{2}$
  - $(z+1)^2\cdot P_3(z)$ is analytic at $z=-1$
  $\left((z+1)^2\cdot P_3(z)\right)\Big|_{z=-1}=0$
  - $z=-1$is a regular singular point
  Check to see if z_0 is a regular singular point
  $z_0=-1$
- Multiply by denominators
$(z^2-1)\left(\frac{d^2}{dz^2}y(z)\right)+3z\left(\frac{d}{dz}y(z)\right)-\lambda y(z)=0$
- Change variables using $z=u-1$ so that the regular singular point is at $u=0$
$(u^2-2u)\left(\frac{d^2}{du^2}y(u)\right)+(3u-3)\left(\frac{d}{du}y(u)\right)-\lambda y(u)=0$
- Assume series solution for $y(u)$
$y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

☐ Rewrite ODE with series expansions
  - Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$
  $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,u^{k+r-1+m}$
  - Shift index using $k->k+1-m$
  $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,u^{k+r}$
  - Convert $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m=1..2$
  $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)(k+r-1)\,u^{k+r-2+m}$
  - Shift index using $k->k+2-m$
  $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=-2+m}^{\infty}a_{k+2-m}(k+2-m+r)(k+1-m+r)\,u^{k+r}$
  Rewrite ODE with series expansions
  $-a_0r(1+2r)\,u^{-1+r}+\left(\sum_{k=0}^{\infty}\left(-a_{k+1}(k+1+r)(2k+3+2r)+a_k(k^2+2kr+r^2+2k-\lambda+2r)\right)\right.$
- $a_0$cannot be 0 by assumption, giving the indicial equation

$$-r(1+2r)=0$$

- Values of r that satisfy the indicial equation

$$r\in\left\{0,-\frac{1}{2}\right\}$$

- Each term in the series must be 0, giving the recursion relation

$$-2(k+1+r)\left(k+r+\frac{3}{2}\right)a_{k+1}+\left(k^2+(2r+2)\,k+r^2+2r-\lambda\right)a_k=0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1}=\frac{(k^2+2kr+r^2+2k-\lambda+2r)\,a_k}{(k+1+r)\,(2k+3+2r)}$$

- Recursion relation for $r=0$

$$a_{k+1}=\frac{(k^2+2k-\lambda)\,a_k}{(k+1)\,(2k+3)}$$

- Solution for $r=0$

$$\left[y(u)=\sum_{k=0}^{\infty}a_k u^k,a_{k+1}=\frac{(k^2+2k-\lambda)\,a_k}{(k+1)\,(2k+3)}\right]$$

- Revert the change of variables $u=z+1$

$$\left[y(z)=\sum_{k=0}^{\infty}a_k(z+1)^k,a_{k+1}=\frac{(k^2+2k-\lambda)\,a_k}{(k+1)\,(2k+3)}\right]$$

- Recursion relation for $r=-\frac{1}{2}$

$$a_{k+1}=\frac{(k^2+k-\lambda-\frac{3}{4})\,a_k}{(k+\frac{1}{2})\,(2k+2)}$$

- Solution for $r=-\frac{1}{2}$

$$\left[y(u)=\sum_{k=0}^{\infty}a_k u^{k-\frac{1}{2}},a_{k+1}=\frac{(k^2+k-\lambda-\frac{3}{4})\,a_k}{(k+\frac{1}{2})\,(2k+2)}\right]$$

- Revert the change of variables $u=z+1$

$$\left[y(z)=\sum_{k=0}^{\infty}a_k(z+1)^{k-\frac{1}{2}},a_{k+1}=\frac{(k^2+k-\lambda-\frac{3}{4})\,a_k}{(k+\frac{1}{2})\,(2k+2)}\right]$$

- Combine solutions and rename parameters

$$\left[y(z)=\left(\sum_{k=0}^{\infty}a_k(z+1)^k\right)+\left(\sum_{k=0}^{\infty}b_k(z+1)^{k-\frac{1}{2}}\right),a_{k+1}=\frac{(k^2+2k-\lambda)\,a_k}{(k+1)\,(2k+3)},b_{k+1}=\frac{(k^2+k-\lambda-\frac{3}{4})\,b_k}{(k+\frac{1}{2})\,(2k+2)}\right]$$

2.1.215 Problem 218

Internal problem ID [9387]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 218
Date solved : `Monday, January 27, 2025 at 06:02:12 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$4zy'' + 2(1 - z)\, y' - y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.237 (sec)

Writing the ode as

$$\begin{aligned} 4zy'' + (-2z + 2)\, y' - y &= 0 &(1)\\ Ay'' + By' + Cy &= 0 &(2) \end{aligned}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4z\\ B &= -2z + 2 &(3)\\ C &= -1 \end{aligned}$$

Applying the Liouville transformation on the dependent variable gives

$$z(z) = y e^{\int \frac{B}{2A}\, dz}$$

Then (2) becomes

$$z''(z) = rz(z) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} &(5)\\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{z^2 + 2z - 3}{16z^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= z^2 + 2z - 3\\ t &= 16z^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(z) = \left(\frac{z^2 + 2z - 3}{16z^2}\right) z(z) \tag{7}$$

Equation (7) is now solved. After finding $z(z)$ then y is found using the inverse transformation

$$y = z(z)\, e^{-\int \frac{B}{2A}\, dz}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.412: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16z^2$. There is a pole at $z = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{16} + \frac{1}{8z} - \frac{3}{16z^2}$$

For the pole at $z = 0$ let b be the coefficient of $\frac{1}{z^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{3}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{4} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving z^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i z^i \\ &= \sum_{i=0}^{0} a_i z^i \end{aligned} \tag{8}$$

Let a be the coefficient of $z^v = z^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{4} + \frac{1}{4z} - \frac{1}{2z^2} + \frac{1}{2z^3} - \frac{1}{z^4} + \frac{2}{z^5} - \frac{9}{2z^6} + \frac{21}{2z^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{4}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i z^i \\ &= \frac{1}{4}\end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $z^{v-1} = z^{-1} = \frac{1}{z}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{16}$$

This shows that the coefficient of $\frac{1}{z}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{z}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{z}$ in r will be the coefficient in R of the term in z of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned}r &= \frac{s}{t} \\ &= \frac{z^2 + 2z - 3}{16z^2} \\ &= Q + \frac{R}{16z^2} \\ &= \left(\frac{1}{16}\right) + \left(\frac{2z - 3}{16z^2}\right) \\ &= \frac{1}{16} + \frac{2z - 3}{16z^2}\end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term z in the remainder R is 2. Dividing this by leading coefficient in t which is 16 gives $\frac{1}{8}$. Now b can be found.

$$\begin{aligned}b &= \left(\frac{1}{8}\right) - (0) \\ &= \frac{1}{8}\end{aligned}$$

Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= \frac{1}{4} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{\frac{1}{8}}{\frac{1}{4}} - 0\right) &= \frac{1}{4} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{\frac{1}{8}}{\frac{1}{4}} - 0\right) &= -\frac{1}{4}\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{z^2 + 2z - 3}{16z^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{3}{4}$	$\frac{1}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{4}$	$\frac{1}{4}$	$-\frac{1}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{1}{4}$ then

$$\begin{aligned} d &= \alpha_\infty^+ - (\alpha_{c_1}^-) \\ &= \frac{1}{4} - \left(\frac{1}{4}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{z-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{z-c_1} \right) + (+)[\sqrt{r}]_\infty \\ &= \frac{1}{4z} + \left(\frac{1}{4}\right) \\ &= \frac{1}{4} + \frac{1}{4z} \\ &= \frac{z+1}{4z} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(z)$ of degree $d = 0$ to solve the ode. The polynomial $p(z)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(z) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{4} + \frac{1}{4z}\right)(0) + \left(\left(-\frac{1}{4z^2}\right) + \left(\frac{1}{4} + \frac{1}{4z}\right)^2 - \left(\frac{z^2+2z-3}{16z^2}\right)\right) = 0$$
$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(z) &= p e^{\int \omega \, dz} \\ &= e^{\int \left(\frac{1}{4} + \frac{1}{4z}\right) dz} \\ &= z^{1/4} e^{\frac{z}{4}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dz} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-2z+2}{4z}\,dz} \\
&= z_1 e^{\frac{z}{4}-\frac{\ln(z)}{4}} \\
&= z_1\left(\frac{e^{\frac{z}{4}}}{z^{1/4}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = e^{\frac{z}{2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dz}}{y_1^2}\,dz$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-2z+2}{4z}\,dz}}{(y_1)^2}\,dz \\
&= y_1 \int \frac{e^{\frac{z}{2}-\frac{\ln(z)}{2}}}{(y_1)^2}\,dz \\
&= y_1\left(\sqrt{\pi}\,\sqrt{2}\,\operatorname{erf}\left(\frac{\sqrt{2}\,\sqrt{z}}{2}\right)\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(e^{\frac{z}{2}}\right) + c_2\left(e^{\frac{z}{2}}\left(\sqrt{\pi}\,\sqrt{2}\,\operatorname{erf}\left(\frac{\sqrt{2}\,\sqrt{z}}{2}\right)\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$4z\left(\frac{d^2}{dz^2}y(z)\right) + 2(1-z)\left(\frac{d}{dz}y(z)\right) - y(z) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dz^2}y(z)$

- Isolate 2nd derivative

  $\frac{d^2}{dz^2}y(z) = \frac{y(z)}{4z} + \frac{(z-1)\left(\frac{d}{dz}y(z)\right)}{2z}$

- Group terms with $y(z)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d^2}{dz^2}y(z) - \frac{(z-1)\left(\frac{d}{dz}y(z)\right)}{2z} - \frac{y(z)}{4z} = 0$

☐ Check to see if $z_0 = 0$ is a regular singular point

  ◦ Define functions

    $\left[P_2(z) = -\frac{z-1}{2z}, P_3(z) = -\frac{1}{4z}\right]$

Solve

$$f''+2(z-1)\,f'+4f=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.223 (sec)

Writing the ode as

$$f''+(2z-2)\,f'+4f=0 \tag{1}$$
$$Af''+Bf'+Cf=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A&=1\\ B&=2z-2\\ C&=4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(z)=fe^{\int \frac{B}{2A}\,dz}$$

Then (2) becomes

$$z''(z)=rz(z) \tag{4}$$

Where r is given by

$$\begin{aligned} r&=\frac{s}{t}\\ &=\frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r=\frac{z^2-2z-2}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s&=z^2-2z-2\\ t&=1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(z)=\left(z^2-2z-2\right)z(z) \tag{7}$$

Equation (7) is now solved. After finding $z(z)$ then f is found using the inverse transformation

$$f = z(z)\, e^{-\int \frac{B}{2A}\, dz}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.414: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 2 \\ &= -2 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving z^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i z^i \\ &= \sum_{i=0}^{1} a_i z^i \end{aligned} \tag{8}$$

Let a be the coefficient of $z^v = z^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx z - 1 - \frac{3}{2z} - \frac{3}{2z^2} - \frac{21}{8z^3} - \frac{39}{8z^4} - \frac{159}{16z^5} - \frac{339}{16z^6} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = 1$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i z^i \\ &= z - 1 \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $z^{v-1} = z^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = z^2 - 2z + 1$$

This shows that the coefficient of 1 in the above is 1. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{z^2 - 2z - 2}{1} \\ &= Q + \frac{R}{1} \\ &= \left(z^2 - 2z - 2\right) + (0) \\ &= z^2 - 2z - 2 \end{aligned}$$

We see that the coefficient of the term $\frac{1}{z}$ in the quotient is -2. Now b can be found.

$$\begin{aligned} b &= (-2) - (1) \\ &= -3 \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= z - 1 \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-3}{1} - 1\right) &= -2 \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-3}{1} - 1\right) &= 1 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = z^2 - 2z - 2$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-2	$z - 1$	-2	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$, and since there are no poles then

$$\begin{aligned} d &= \alpha_\infty^- \\ &= 1 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{z-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}\omega &= (-)[\sqrt{r}]_\infty \\ &= 0 + (-)\,(z-1) \\ &= 1-z \\ &= 1-z\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(z)$ of degree $d=1$ to solve the ode. The polynomial $p(z)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\,p = 0 \tag{1A}$$

Let

$$p(z) = z + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned}(0) + 2(1-z)\,(1) + \left((-1) + (1-z)^2 - (z^2-2z-2)\right) &= 0 \\ 2 + 2a_0 &= 0\end{aligned}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = -1\}$$

Substituting these coefficients in $p(z)$ in eq. (2A) results in

$$p(z) = z - 1$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}z_1(z) &= pe^{\int \omega\,dz} \\ &= (z-1)\,\mathrm{e}^{\int (1-z)dz} \\ &= (z-1)\,\mathrm{e}^{z-\frac{1}{2}z^2} \\ &= (z-1)\,\mathrm{e}^{-\frac{z(-2+z)}{2}}\end{aligned}$$

The first solution to the original ode in f is found from

$$\begin{aligned}f_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dz} \\ &= z_1 e^{-\int \frac{1}{2}\frac{2z-2}{1}\,dz} \\ &= z_1 e^{z-\frac{1}{2}z^2} \\ &= z_1\left(\mathrm{e}^{-\frac{z(-2+z)}{2}}\right)\end{aligned}$$

Which simplifies to

$$f_1 = \mathrm{e}^{-z(-2+z)}(z-1)$$

The second solution f_2 to the original ode is found using reduction of order

$$f_2 = f_1 \int \frac{e^{\int -\frac{B}{A}\,dz}}{f_1^2}\,dz$$

Substituting gives

$$\begin{aligned}
f_2 &= f_1 \int \frac{e^{\int -\frac{2z-2}{1}\, dz}}{(f_1)^2}\, dz \\
&= f_1 \int \frac{e^{-z^2+2z}}{(f_1)^2}\, dz \\
&= f_1 \left(-\frac{e^{(z-1)^2-1}}{z-1} - i\sqrt{\pi}\, e^{-1} \operatorname{erf}\left(i(z-1)\right) \right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
f &= c_1 f_1 + c_2 f_2 \\
&= c_1 \left(e^{-z(-2+z)}(z-1)\right) + c_2 \left(e^{-z(-2+z)}(z-1) \left(-\frac{e^{(z-1)^2-1}}{z-1} - i\sqrt{\pi}\, e^{-1} \operatorname{erf}\left(i(z-1)\right) \right) \right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve
$\frac{d^2}{dz^2} f(z) + 2(z-1)\left(\frac{d}{dz} f(z)\right) + 4f(z) = 0$

- Highest derivative means the order of the ODE is 2
  $\frac{d^2}{dz^2} f(z)$
- Isolate 2nd derivative
  $\frac{d^2}{dz^2} f(z) = -2(z-1)\left(\frac{d}{dz} f(z)\right) - 4f(z)$
- Group terms with $f(z)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin
  $\frac{d^2}{dz^2} f(z) + (-2+2z)\left(\frac{d}{dz} f(z)\right) + 4f(z) = 0$
- Assume series solution for $f(z)$
  $f(z) = \sum_{k=0}^{\infty} a_k z^k$

☐ Rewrite DE with series expansions

- ◦ Convert $z^m \cdot \left(\frac{d}{dz} f(z)\right)$ to series expansion for $m = 0..1$
  $z^m \cdot \left(\frac{d}{dz} f(z)\right) = \sum_{k=\max(0,1-m)}^{\infty} a_k k\, z^{k-1+m}$
- ◦ Shift index using $k- >k+1-m$
  $z^m \cdot \left(\frac{d}{dz} f(z)\right) = \sum_{k=\max(0,1-m)+m-1}^{\infty} a_{k+1-m}(k+1-m)\, z^k$
- ◦ Convert $\frac{d^2}{dz^2} f(z)$ to series expansion
  $\frac{d^2}{dz^2} f(z) = \sum_{k=2}^{\infty} a_k k(k-1)\, z^{k-2}$
- ◦ Shift index using $k- >k+2$
  $\frac{d^2}{dz^2} f(z) = \sum_{k=0}^{\infty} a_{k+2}(k+2)(k+1)\, z^k$

Rewrite DE with series expansions
$\sum_{k=0}^{\infty} \left(a_{k+2}(k+2)(k+1) - 2a_{k+1}(k+1) + 2a_k(k+2)\right) z^k = 0$

- Each term in the series must be 0, giving the recursion relation

$$k^2 a_{k+2} + (2a_k - 2a_{k+1} + 3a_{k+2})\, k + 4a_k - 2a_{k+1} + 2a_{k+2} = 0$$

- Recursion relation that defines the series solution to the ODE

$$\left[f(z) = \sum_{k=0}^{\infty} a_k z^k, a_{k+2} = -\frac{2(a_k k - a_{k+1} k + 2a_k - a_{k+1})}{k^2 + 3k + 2}\right]$$

Solve

$$zy'' - 2y' + zy = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.267 (sec)

Writing the ode as

$$zy'' - 2y' + zy = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= z \\ B &= -2 \\ C &= z \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(z) = ye^{\int \frac{B}{2A}\, dz}$$

Then (2) becomes

$$z''(z) = rz(z) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-z^2 + 2}{z^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -z^2 + 2 \\ t &= z^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(z) = \left(\frac{-z^2 + 2}{z^2}\right) z(z) \tag{7}$$

Equation (7) is now solved. After finding $z(z)$ then y is found using the inverse transformation

$$y = z(z)\, e^{-\int \frac{B}{2A}\, dz}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.416: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = z^2$. There is a pole at $z = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -1 + \frac{2}{z^2}$$

For the pole at $z = 0$ let b be the coefficient of $\frac{1}{z^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1 \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving z^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i z^i \\ &= \sum_{i=0}^{0} a_i z^i \end{aligned} \tag{8}$$

Let a be the coefficient of $z^v = z^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx i - \frac{i}{z^2} - \frac{i}{2z^4} - \frac{i}{2z^6} - \frac{5i}{8z^8} - \frac{7i}{8z^{10}} - \frac{21i}{16z^{12}} - \frac{33i}{16z^{14}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = i$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i z^i \\ &= i \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $z^{v-1} = z^{-1} = \frac{1}{z}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = -1$$

This shows that the coefficient of $\frac{1}{z}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{z}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{z}$ in r will be the coefficient in R of the term in z of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{-z^2 + 2}{z^2} \\ &= Q + \frac{R}{z^2} \\ &= (-1) + \left(\frac{2}{z^2}\right) \\ &= -1 + \frac{2}{z^2} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term z in the remainder R is 0. Dividing this by leading coefficient in t which is 1 gives 0. Now b can be found.

$$\begin{aligned} b &= (0) - (0) \\ &= 0 \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= i \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) = \frac{1}{2}\left(\frac{0}{i} - 0\right) = 0 \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) = \frac{1}{2}\left(-\frac{0}{i} - 0\right) = 0 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{-z^2 + 2}{z^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	2	-1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	i	0	0

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 0$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\ &= 0 - (-1) \\ &= 1 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{z-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{z-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= -\frac{1}{z} + (-)(i) \\ &= -\frac{1}{z} - i \\ &= -\frac{1}{z} - i \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(z)$ of degree $d = 1$ to solve the ode. The polynomial $p(z)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(z) = z + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{z} - i\right)(1) + \left(\left(\frac{1}{z^2}\right) + \left(-\frac{1}{z} - i\right)^2 - \left(\frac{-z^2+2}{z^2}\right) \right) = 0$$

$$\frac{2ia_0 - 2}{z} = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = -i\}$$

Substituting these coefficients in $p(z)$ in eq. (2A) results in

$$p(z) = z - i$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(z) &= p e^{\int \omega \, dz} \\ &= (z-i)\, e^{\int \left(-\frac{1}{z} - i\right) dz} \\ &= (z-i)\, e^{-\ln(z) - iz} \\ &= \frac{(z-i)\, e^{-iz}}{z} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dz} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-2}{z}\,dz} \\ &= z_1 e^{\ln(z)} \\ &= z_1(z) \end{aligned}$$

Which simplifies to

$$y_1 = (z-i)\,e^{-iz}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dz}}{y_1^2}\,dz$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-2}{z}\,dz}}{(y_1)^2}\,dz \\ &= y_1 \int \frac{e^{2\ln(z)}}{(y_1)^2}\,dz \\ &= y_1 \left(\frac{(iz-1)\,e^{2iz}}{-2z+2i}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left((z-i)\,e^{-iz}\right) + c_2\left((z-i)\,e^{-iz}\left(\frac{(iz-1)\,e^{2iz}}{-2z+2i}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

2.1.218 Problem 221

Internal problem ID [9390]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 221
Date solved : `Monday, January 27, 2025 at 06:02:14 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$zy'' + (2z-3)\,y' + \frac{4y}{z} = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.276 (sec)

Writing the ode as

$$zy'' + (2z-3)\,y' + \frac{4y}{z} = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= z \\ B &= 2z-3 \\ C &= \frac{4}{z} \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(z) = ye^{\int \frac{B}{2A}\,dz}$$

Then (2) becomes

$$z''(z) = rz(z) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{4z^2 - 12z - 1}{4z^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 4z^2 - 12z - 1 \\ t &= 4z^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(z) = \left(\frac{4z^2 - 12z - 1}{4z^2}\right) z(z) \tag{7}$$

Equation (7) is now solved. After finding $z(z)$ then y is found using the inverse transformation

$$y = z(z)\, e^{-\int \frac{B}{2A}\, dz}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.418: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4z^2$. There is a pole at $z = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = 1 - \frac{1}{4z^2} - \frac{3}{z}$$

For the pole at $z = 0$ let b be the coefficient of $\frac{1}{z^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving z^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i z^i \\
&= \sum_{i=0}^{0} a_i z^i
\end{aligned} \tag{8}$$

Let a be the coefficient of $z^v = z^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx 1 - \frac{3}{2z} - \frac{5}{4z^2} - \frac{15}{8z^3} - \frac{115}{32z^4} - \frac{495}{64z^5} - \frac{2285}{128z^6} - \frac{11055}{256z^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = 1$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i z^i \\
&= 1
\end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $z^{v-1} = z^{-1} = \frac{1}{z}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = 1$$

This shows that the coefficient of $\frac{1}{z}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{z}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{z}$ in r will be the coefficient in R of the term in z of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{4z^2 - 12z - 1}{4z^2} \\
&= Q + \frac{R}{4z^2} \\
&= (1) + \left(\frac{-12z - 1}{4z^2}\right) \\
&= 1 + \frac{-12z - 1}{4z^2}
\end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term z in the remainder R is -12. Dividing this by leading coefficient in t which is 4 gives -3. Now b can be found.

$$\begin{aligned}
b &= (-3) - (0) \\
&= -3
\end{aligned}$$

Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 1 \\
\alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-3}{1} - 0\right) &&= -\frac{3}{2} \\
\alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-3}{1} - 0\right) &&= \frac{3}{2}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{4z^2 - 12z - 1}{4z^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	1	$-\frac{3}{2}$	$\frac{3}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{3}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^- - (\alpha_{c_1}^+) \\ &= \frac{3}{2} - \left(\frac{1}{2}\right) \\ &= 1 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{z-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{z-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{1}{2z} + (-)(1) \\ &= \frac{1}{2z} - 1 \\ &= \frac{1}{2z} - 1 \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(z)$ of degree $d = 1$ to solve the ode. The polynomial $p(z)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(z) = z + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{2z} - 1\right)(1) + \left(\left(-\frac{1}{2z^2}\right) + \left(\frac{1}{2z} - 1\right)^2 - \left(\frac{4z^2 - 12z - 1}{4z^2}\right) \right) = 0$$

$$\frac{1 + 2a_0}{z} = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\left\{ a_0 = -\frac{1}{2} \right\}$$

Substituting these coefficients in $p(z)$ in eq. (2A) results in

$$p(z) = z - \frac{1}{2}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(z) &= p e^{\int \omega \, dz} \\ &= \left(z - \frac{1}{2}\right) e^{\int \left(\frac{1}{2z} - 1\right) dz} \\ &= \left(z - \frac{1}{2}\right) e^{-z + \frac{\ln(z)}{2}} \\ &= \frac{(-1 + 2z)\sqrt{z}\, e^{-z}}{2} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dz} \\ &= z_1 e^{-\int \frac{1}{2}\frac{2z-3}{z} \, dz} \\ &= z_1 e^{-z + \frac{3\ln(z)}{2}} \\ &= z_1 \left(z^{3/2} e^{-z}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{z^2 e^{-2z}(-1 + 2z)}{2}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dz}}{y_1^2} \, dz$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{2z-3}{z} \, dz}}{(y_1)^2} \, dz \\ &= y_1 \int \frac{e^{-2z + 3\ln(z)}}{(y_1)^2} \, dz \\ &= y_1 \left(-4 \operatorname{Ei}_1(-2z) - \frac{4 e^{2z}}{-1 + 2z}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\frac{z^2 e^{-2z}(-1 + 2z)}{2}\right) + c_2 \left(\frac{z^2 e^{-2z}(-1 + 2z)}{2} \left(-4 \operatorname{Ei}_1(-2z) - \frac{4 e^{2z}}{-1 + 2z}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$z\left(\frac{d^2}{dz^2}y(z)\right)+(-3+2z)\left(\frac{d}{dz}y(z)\right)+\frac{4y(z)}{z}=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dz^2}y(z)$

- Isolate 2nd derivative

  $\frac{d^2}{dz^2}y(z)=-\frac{4y(z)}{z^2}-\frac{(-3+2z)\left(\frac{d}{dz}y(z)\right)}{z}$

- Group terms with $y(z)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dz^2}y(z)+\frac{(-3+2z)\left(\frac{d}{dz}y(z)\right)}{z}+\frac{4y(z)}{z^2}=0$

□ Check to see if $z_0=0$ is a regular singular point

- ○ Define functions

  $\left[P_2(z)=\frac{-3+2z}{z},P_3(z)=\frac{4}{z^2}\right]$

- ○ $z\cdot P_2(z)$ is analytic at $z=0$

  $\left.(z\cdot P_2(z))\right|_{z=0}=-3$

- ○ $z^2\cdot P_3(z)$ is analytic at $z=0$

  $\left.(z^2\cdot P_3(z))\right|_{z=0}=4$

- ○ $z=0$is a regular singular point

  Check to see if $z_0=0$ is a regular singular point

  $z_0=0$

- Multiply by denominators

  $\left(\frac{d^2}{dz^2}y(z)\right)z^2+z(-3+2z)\left(\frac{d}{dz}y(z)\right)+4y(z)=0$

- Assume series solution for $y(z)$

  $y(z)=\sum_{k=0}^{\infty}a_k z^{k+r}$

□ Rewrite ODE with series expansions

- ○ Convert $z^m\cdot\left(\frac{d}{dz}y(z)\right)$ to series expansion for $m=1..2$

  $z^m\cdot\left(\frac{d}{dz}y(z)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,z^{k+r-1+m}$

- ○ Shift index using $k->k+1-m$

  $z^m\cdot\left(\frac{d}{dz}y(z)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,z^{k+r}$

- ○ Convert $z^2\cdot\left(\frac{d^2}{dz^2}y(z)\right)$ to series expansion

  $z^2\cdot\left(\frac{d^2}{dz^2}y(z)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,z^{k+r}$

  Rewrite ODE with series expansions

  $a_0(-2+r)^2\,z^r+\left(\sum_{k=1}^{\infty}\left(a_k(k+r-2)^2+2a_{k-1}(k+r-1)\right)z^{k+r}\right)=0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-2+r)^2=0$

- Values of r that satisfy the indicial equation

  $r=2$

- Each term in the series must be 0, giving the recursion relation

  $a_k(k+r-2)^2+2a_{k-1}(k+r-1)=0$

- Shift index using $k->k+1$

$$a_{k+1}(k+r-1)^2 + 2a_k(k+r) = 0$$

- Recursion relation that defines series solution to ODE
  $a_{k+1} = -\frac{2a_k(k+r)}{(k+r-1)^2}$
- Recursion relation for $r = 2$
  $a_{k+1} = -\frac{2a_k(k+2)}{(k+1)^2}$
- Solution for $r = 2$
  $\left[y(z) = \sum_{k=0}^{\infty} a_k z^{k+2}, a_{k+1} = -\frac{2a_k(k+2)}{(k+1)^2}\right]$

2.1.219 Problem 222

Internal problem ID [9391]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 222
Date solved : `Monday, January 27, 2025 at 06:02:14 PM`
CAS classification : `[_erf]`

Solve

$$y'' + 2xy' + 4y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.188 (sec)

Writing the ode as

$$y'' + 2xy' + 4y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 2x \\ C &= 4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 - 3}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2 - 3 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(x^2 - 3\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.420: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 2 \\ &= -2 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx x - \frac{3}{2x} - \frac{9}{8x^3} - \frac{27}{16x^5} - \frac{405}{128x^7} - \frac{1701}{256x^9} - \frac{15309}{1024x^{11}} - \frac{72171}{2048x^{13}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = 1$$

From Eq. (9) the sum up to $v = 1$ gives

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\
&= x \qquad (10)
\end{aligned}
$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = x^2$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{x^2 - 3}{1} \\
&= Q + \frac{R}{1} \\
&= (x^2 - 3) + (0) \\
&= x^2 - 3
\end{aligned}
$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is -3. Now b can be found.

$$
\begin{aligned}
b &= (-3) - (0) \\
&= -3
\end{aligned}
$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= x \\
\alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-3}{1} - 1\right) &= -2 \\
\alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-3}{1} - 1\right) &= 1
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = x^2 - 3$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-2	x	-2	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$, and since there are no poles then

$$
\begin{aligned}
d &= \alpha_\infty^- \\
&= 1
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}\omega &= (-)[\sqrt{r}]_\infty \\ &= 0 + (-)\,(x) \\ &= -x \\ &= -x\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\,p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned}(0) + 2(-x)\,(1) + \left((-1) + (-x)^2 - (x^2-3)\right) &= 0 \\ 2a_0 &= 0\end{aligned}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}z_1(x) &= pe^{\int \omega\, dx} \\ &= (x)\,\mathrm{e}^{\int -x dx} \\ &= (x)\,\mathrm{e}^{-\frac{x^2}{2}} \\ &= x\,\mathrm{e}^{-\frac{x^2}{2}}\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{2x}{1}\, dx} \\ &= z_1 e^{-\frac{x^2}{2}} \\ &= z_1 \left(\mathrm{e}^{-\frac{x^2}{2}}\right)\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-x^2} x$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{2x}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-x^2}}{(y_1)^2}\,dx \\
&= y_1 \left(-\frac{\mathrm{e}^{x^2}}{x} + \sqrt{\pi}\,\mathrm{erfi}\,(x)\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{-x^2} x\right) + c_2\left(\mathrm{e}^{-x^2} x\left(-\frac{\mathrm{e}^{x^2}}{x} + \sqrt{\pi}\,\mathrm{erfi}\,(x)\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$\frac{d^2}{dx^2}y(x) + 2x\left(\frac{d}{dx}y(x)\right) + 4y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^k$

☐ Rewrite DE with series expansions

  ◦ Convert $x \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion

  $x \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k k\, x^k$

  ◦ Convert $\frac{d^2}{dx^2}y(x)$ to series expansion

  $\frac{d^2}{dx^2}y(x) = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$

  ◦ Shift index using $k- >k+2$

  $\frac{d^2}{dx^2}y(x) = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$

  Rewrite DE with series expansions

  $\sum_{k=0}^{\infty} \left(a_{k+2}(k+2)\,(k+1) + 2a_k(k+2)\right) x^k = 0$

- Each term in the series must be 0, giving the recursion relation

  $(k+2)\left(k a_{k+2} + 2a_k + a_{k+2}\right) = 0$

- Recursion relation that defines the series solution to the ODE

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^k, a_{k+2} = -\frac{2a_k}{k+1}\right]$

2.1.220 Problem 223

Internal problem ID [9392]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 223
Date solved : `Monday, January 27, 2025 at 06:02:15 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$y'' + xy' + 3y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.246 (sec)

Writing the ode as

$$y'' + xy' + 3y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= x \\ C &= 3 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 - 10}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2 - 10 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2}{4} - \frac{5}{2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.422: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 2 \\ &= -2 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x}{2} - \frac{5}{2x} - \frac{25}{4x^3} - \frac{125}{4x^5} - \frac{3125}{16x^7} - \frac{21875}{16x^9} - \frac{328125}{32x^{11}} - \frac{2578125}{32x^{13}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= \frac{x}{2}\end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{x^2}{4}$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned}r &= \frac{s}{t} \\ &= \frac{x^2 - 10}{4} \\ &= Q + \frac{R}{4} \\ &= \left(\frac{x^2}{4} - \frac{5}{2}\right) + (0) \\ &= \frac{x^2}{4} - \frac{5}{2}\end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is $-\frac{5}{2}$. Now b can be found.

$$\begin{aligned}b &= \left(-\frac{5}{2}\right) - (0) \\ &= -\frac{5}{2}\end{aligned}$$

Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= \frac{x}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{5}{2}}{\frac{1}{2}} - 1\right) &&= -3 \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{5}{2}}{\frac{1}{2}} - 1\right) &&= 2\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2}{4} - \frac{5}{2}$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-2	$\frac{x}{2}$	-3	2

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^-=2$, and since there are no poles then

$$\begin{aligned} d &= \alpha_\infty^- \\ &= 2 \end{aligned}$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$\omega=\sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c+\frac{\alpha_c^{s(c)}}{x-c}\right)+s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= (-)[\sqrt{r}]_\infty \\ &= 0+(-)\left(\frac{x}{2}\right) \\ &= -\frac{x}{2} \\ &= -\frac{x}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=2$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p''+2\omega p'+\left(\omega'+\omega^2-r\right)p=0 \tag{1A}$$

Let

$$p(x)=x^2+a_1x+a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (2)+2\left(-\frac{x}{2}\right)(2x+a_1)+\left(\left(-\frac{1}{2}\right)+\left(-\frac{x}{2}\right)^2-\left(\frac{x^2}{4}-\frac{5}{2}\right)\right) &= 0 \\ a_1x+2a_0+2 &= 0 \end{aligned}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0=-1, a_1=0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x)=x^2-1$$

Therefore the first solution to the ode $z''=rz$ is

$$\begin{aligned} z_1(x) &= pe^{\int \omega\,dx} \\ &= \left(x^2-1\right)e^{\int -\frac{x}{2}dx} \\ &= \left(x^2-1\right)e^{-\frac{x^2}{4}} \\ &= \left(x^2-1\right)e^{-\frac{x^2}{4}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1e^{-\int \frac{1}{2}\frac{x}{1}\,dx} \\ &= z_1e^{-\frac{x^2}{4}} \\ &= z_1\left(e^{-\frac{x^2}{4}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-\frac{x^2}{2}}\left(x^2-1\right)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{x}{1}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-\frac{x^2}{2}}}{(y_1)^2}\, dx \\ &= y_1 \left(\int \frac{\mathrm{e}^{\frac{x^2}{2}}}{(x^2-1)^2} dx\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\mathrm{e}^{-\frac{x^2}{2}}\left(x^2-1\right)\right) + c_2\left(\mathrm{e}^{-\frac{x^2}{2}}\left(x^2-1\right)\left(\int \frac{\mathrm{e}^{\frac{x^2}{2}}}{(x^2-1)^2} dx\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$\frac{d^2}{dx^2}y(x) + x\left(\frac{d}{dx}y(x)\right) + 3y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Assume series solution for $y(x)$

2.1.221 Problem 224

Internal problem ID [9393]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 224
Date solved : `Monday, January 27, 2025 at 06:02:16 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$y'' - x^2 y' - 3xy = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.250 (sec)

Writing the ode as

$$y'' - x^2 y' - 3xy = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -x^2 \\ C &= -3x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x(x^3 + 8)}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x(x^3 + 8) \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x(x^3 + 8)}{4} \right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.424: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 4 \\ &= -4 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -4 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -4$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{4}{2} = 2$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{2} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^2$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x^2}{2} + \frac{2}{x} - \frac{4}{x^4} + \frac{16}{x^7} - \frac{80}{x^{10}} + \frac{448}{x^{13}} - \frac{2688}{x^{16}} + \frac{16896}{x^{19}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 2$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{2} a_i x^i \\ &= \frac{x^2}{2}\end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^1 = x$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{x^4}{4}$$

This shows that the coefficient of x in the above is 0. Now we need to find the coefficient of x in r. How this is done depends on if $v = 0$ or not. Since $v = 2$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of x in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned}r &= \frac{s}{t} \\ &= \frac{x(x^3+8)}{4} \\ &= Q + \frac{R}{4} \\ &= \left(\frac{1}{4}x^4 + 2x\right) + (0) \\ &= \frac{1}{4}x^4 + 2x\end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is 2. Now b can be found.

$$\begin{aligned}b &= (2) - (0) \\ &= 2\end{aligned}$$

Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= \frac{x^2}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{2}{\frac{1}{2}} - 2\right) &&= 1 \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{2}{\frac{1}{2}} - 2\right) &&= -3\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x(x^3+8)}{4}$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-4	$\frac{x^2}{2}$	1	-3

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = 1$, and since there are no poles, then

$$\begin{aligned} d &= \alpha_\infty^+ \\ &= 1 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= (+)[\sqrt{r}]_\infty \\ &= 0 + \left(\frac{x^2}{2}\right) \\ &= \frac{x^2}{2} \\ &= \frac{x^2}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{x^2}{2}\right)(1) + \left((x) + \left(\frac{x^2}{2}\right)^2 - \left(\frac{x(x^3+8)}{4}\right)\right) = 0$$
$$-xa_0 = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= pe^{\int \omega\, dx} \\ &= (x)\,\mathrm{e}^{\int \frac{x^2}{2} dx} \\ &= (x)\,\mathrm{e}^{\frac{x^3}{6}} \\ &= x\,\mathrm{e}^{\frac{x^3}{6}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-x^2}{1}\, dx} \\ &= z_1 e^{\frac{x^3}{6}} \\ &= z_1\left(\mathrm{e}^{\frac{x^3}{6}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = e^{\frac{x^3}{3}} x$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-x^2}{1}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{\frac{x^3}{3}}}{(y_1)^2}\, dx \\
&= y_1 \left(\int \frac{e^{-\frac{x^3}{3}}}{x^2} dx\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(e^{\frac{x^3}{3}} x\right) + c_2 \left(e^{\frac{x^3}{3}} x \left(\int \frac{e^{-\frac{x^3}{3}}}{x^2} dx\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$\frac{d^2}{dx^2} y(x) - x^2 \left(\frac{d}{dx} y(x)\right) - 3 x y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2} y(x)$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite ODE with series expansions

  - Convert $x \cdot y(x)$ to series expansion

    $x \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+1}$

  - Shift index using $k- >k-1$

    $x \cdot y(x) = \sum_{k=1}^{\infty} a_{k-1} x^k$

  - Convert $x^2 \cdot \left(\frac{d}{dx} y(x)\right)$ to series expansion

    $x^2 \cdot \left(\frac{d}{dx} y(x)\right) = \sum_{k=0}^{\infty} a_k k\, x^{k+1}$

  - Shift index using $k- >k-1$

    $x^2 \cdot \left(\frac{d}{dx} y(x)\right) = \sum_{k=1}^{\infty} a_{k-1} (k-1)\, x^k$

  - Convert $\frac{d^2}{dx^2} y(x)$ to series expansion

$\frac{d^2}{dx^2}y(x) = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$

- Shift index using $k- >k+2$

  $\frac{d^2}{dx^2}y(x) = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$

  Rewrite ODE with series expansions

  $2a_2 + \left(\sum_{k=1}^{\infty} \left(a_{k+2}(k+2)\,(k+1) - a_{k-1}(k+2)\right) x^k\right) = 0$

- Each term must be 0

  $2a_2 = 0$

- Each term in the series must be 0, giving the recursion relation

  $(k+2)\,(ka_{k+2} - a_{k-1} + a_{k+2}) = 0$

- Shift index using $k- >k+1$

  $(k+3)\,((k+1)\,a_{k+3} - a_k + a_{k+3}) = 0$

- Recursion relation that defines the series solution to the ODE

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^k, a_{k+3} = \frac{a_k}{k+2}, 2a_2 = 0\right]$

Solve

$$\left(-4x^2+1\right)y''-20xy'-16y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.239 (sec)

Writing the ode as

$$\left(-4x^2+1\right)y''-20xy'-16y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=-4x^2+1\\B&=-20x\\C&=-16\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned}r&=\frac{s}{t}\\&=\frac{2AB'-2BA'+B^2-4AC}{4A^2}\end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{-4x^2+6}{\left(4x^2-1\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned}s&=-4x^2+6\\t&=\left(4x^2-1\right)^2\end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{-4x^2+6}{\left(4x^2-1\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.426: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (4x^2 - 1)^2$. There is a pole at $x = \frac{1}{2}$ of order 2. There is a pole at $x = -\frac{1}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{5}{16\left(x - \frac{1}{2}\right)^2} - \frac{7}{8\left(x - \frac{1}{2}\right)} + \frac{5}{16\left(x + \frac{1}{2}\right)^2} + \frac{7}{8\left(x + \frac{1}{2}\right)}$$

For the pole at $x = \frac{1}{2}$ let b be the coefficient of $\frac{1}{\left(x - \frac{1}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{5}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{5}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{1}{4} \end{aligned}$$

For the pole at $x = -\frac{1}{2}$ let b be the coefficient of $\frac{1}{\left(x + \frac{1}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{5}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{5}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{1}{4} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{-4x^2 + 6}{(4x^2 - 1)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{1}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{-4x^2 + 6}{(4x^2 - 1)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
$\frac{1}{2}$	2	0	$\frac{5}{4}$	$-\frac{1}{4}$
$-\frac{1}{2}$	2	0	$\frac{5}{4}$	$-\frac{1}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^- - (\alpha_{c_1}^- + \alpha_{c_2}^-) \\
&= \frac{1}{2} - \left(-\frac{1}{2}\right) \\
&= 1
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x - c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x - c_2} \right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{1}{4\left(x - \frac{1}{2}\right)} - \frac{1}{4\left(x + \frac{1}{2}\right)} + (-)(0) \\
&= -\frac{1}{4\left(x - \frac{1}{2}\right)} - \frac{1}{4\left(x + \frac{1}{2}\right)} \\
&= -\frac{2x}{4x^2 - 1}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{4\left(x-\frac{1}{2}\right)} - \frac{1}{4\left(x+\frac{1}{2}\right)}\right)(1) + \left(\left(\frac{1}{4\left(x-\frac{1}{2}\right)^2} + \frac{1}{4\left(x+\frac{1}{2}\right)^2}\right) + \left(-\frac{1}{4\left(x-\frac{1}{2}\right)} - \frac{1}{4\left(x+\frac{1}{2}\right)}\right)^2 - \left(\right.\right.$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= (x)\, e^{\int \left(-\frac{1}{4\left(x-\frac{1}{2}\right)} - \frac{1}{4\left(x+\frac{1}{2}\right)}\right) dx} \\
&= (x) \frac{1}{\left((2x-1)(2x+1)\right)^{1/4}} \\
&= \frac{x}{\left(4x^2-1\right)^{1/4}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-20x}{-4x^2+1}\, dx} \\
&= z_1 e^{-\frac{5\ln\left(4x^2-1\right)}{4}} \\
&= z_1 \left(\frac{1}{\left(4x^2-1\right)^{5/4}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{x}{\left(4x^2-1\right)^{3/2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-20x}{-4x^2+1}\, dx}}{\left(y_1\right)^2}\, dx \\
&= y_1 \int \frac{e^{-\frac{5\ln\left(4x^2-1\right)}{2}}}{\left(y_1\right)^2}\, dx \\
&= y_1 \left(\frac{\left(4x^2-1\right)^{3/2}}{x} - 4x\sqrt{4x^2-1} + \ln\left(x\sqrt{4} + \sqrt{4x^2-1}\right)\sqrt{4}\right)
\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{x}{(4x^2-1)^{3/2}}\right) \\
&\quad + c_2 \left(\frac{x}{(4x^2-1)^{3/2}} \left(\frac{(4x^2-1)^{3/2}}{x} - 4x\sqrt{4x^2-1} + \ln\left(x\sqrt{4} + \sqrt{4x^2-1}\right)\sqrt{4}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$(-4x^2+1)\left(\frac{d^2}{dx^2}y(x)\right) - 20x\left(\frac{d}{dx}y(x)\right) - 16y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{16y(x)}{4x^2-1} - \frac{20x\left(\frac{d}{dx}y(x)\right)}{4x^2-1}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x) + \frac{20x\left(\frac{d}{dx}y(x)\right)}{4x^2-1} + \frac{16y(x)}{4x^2-1} = 0$

☐ Check to see if x_0 is a regular singular point

  - Define functions

    $\left[P_2(x) = \frac{20x}{4x^2-1}, P_3(x) = \frac{16}{4x^2-1}\right]$

  - $\left(x+\frac{1}{2}\right)\cdot P_2(x)$ is analytic at $x = -\frac{1}{2}$

    $\left(\left(x+\frac{1}{2}\right)\cdot P_2(x)\right)\bigg|_{x=-\frac{1}{2}} = \frac{5}{2}$

  - $\left(x+\frac{1}{2}\right)^2\cdot P_3(x)$ is analytic at $x = -\frac{1}{2}$

    $\left(\left(x+\frac{1}{2}\right)^2\cdot P_3(x)\right)\bigg|_{x=-\frac{1}{2}} = 0$

  - $x = -\frac{1}{2}$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = -\frac{1}{2}$

- Multiply by denominators

  $(4x^2-1)\left(\frac{d^2}{dx^2}y(x)\right) + 20x\left(\frac{d}{dx}y(x)\right) + 16y(x) = 0$

- Change variables using $x = u - \frac{1}{2}$ so that the regular singular point is at $u = 0$

  $(4u^2-4u)\left(\frac{d^2}{du^2}y(u)\right) + (20u-10)\left(\frac{d}{du}y(u)\right) + 16y(u) = 0$

- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

☐ Rewrite ODE with series expansions

  - Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..1$

    $u^m\cdot\left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,u^{k+r-1+m}$

  - Shift index using $k- >k+1-m$

$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$

- Convert $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m = 1..2$

  $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, u^{k+r-2+m}$

- Shift index using $k- >k+2-m$

  $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\, u^{k+r}$

  Rewrite ODE with series expansions

  $-2a_0 r(3+2r)\, u^{-1+r} + \left(\sum_{k=0}^{\infty} \left(-2a_{k+1}(k+1+r)(2k+5+2r) + 4a_k(k+r+2)^2\right) u^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $-2r(3+2r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \left\{0, -\frac{3}{2}\right\}$

- Each term in the series must be 0, giving the recursion relation

  $4a_k(k+r+2)^2 - 4(k+1+r)\left(k+r+\frac{5}{2}\right) a_{k+1} = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+1} = \frac{2a_k(k+r+2)^2}{(k+1+r)(2k+5+2r)}$

- Recursion relation for $r = 0$

  $a_{k+1} = \frac{2a_k(k+2)^2}{(k+1)(2k+5)}$

- Solution for $r = 0$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+1} = \frac{2a_k(k+2)^2}{(k+1)(2k+5)}\right]$

- Revert the change of variables $u = x + \frac{1}{2}$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k\left(x+\frac{1}{2}\right)^k, a_{k+1} = \frac{2a_k(k+2)^2}{(k+1)(2k+5)}\right]$

- Recursion relation for $r = -\frac{3}{2}$

  $a_{k+1} = \frac{2a_k\left(k+\frac{1}{2}\right)^2}{\left(k-\frac{1}{2}\right)(2k+2)}$

- Solution for $r = -\frac{3}{2}$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k-\frac{3}{2}}, a_{k+1} = \frac{2a_k\left(k+\frac{1}{2}\right)^2}{\left(k-\frac{1}{2}\right)(2k+2)}\right]$

- Revert the change of variables $u = x + \frac{1}{2}$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k\left(x+\frac{1}{2}\right)^{k-\frac{3}{2}}, a_{k+1} = \frac{2a_k\left(k+\frac{1}{2}\right)^2}{\left(k-\frac{1}{2}\right)(2k+2)}\right]$

- Combine solutions and rename parameters

  $\left[y(x) = \left(\sum_{k=0}^{\infty} a_k\left(x+\frac{1}{2}\right)^k\right) + \left(\sum_{k=0}^{\infty} b_k\left(x+\frac{1}{2}\right)^{k-\frac{3}{2}}\right), a_{k+1} = \frac{2a_k(k+2)^2}{(k+1)(2k+5)}, b_{k+1} = \frac{2b_k\left(k+\frac{1}{2}\right)^2}{\left(k-\frac{1}{2}\right)(2k+2)}\right]$

2.1.223 Problem 226

Internal problem ID [9395]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 226
Date solved : `Monday, January 27, 2025 at 06:02:17 PM`
CAS classification : `[_Gegenbauer]`

Solve

$$\left(x^2-1\right) y''-6xy'+12y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.192 (sec)

Writing the ode as

$$\left(x^2-1\right) y''-6xy'+12y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A&=x^2-1\\ B&=-6x\\ C&=12 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r&=\frac{s}{t}\\ &=\frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{15}{\left(x^2-1\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s&=15\\ t&=\left(x^2-1\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{15}{\left(x^2-1\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.428: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 0 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (x^2-1)^2$. There is a pole at $x = 1$ of order 2. There is a pole at $x = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{15}{4(x+1)^2} + \frac{15}{4(x+1)} + \frac{15}{4(x-1)^2} - \frac{15}{4(x-1)}$$

For the pole at $x = 1$ let b be the coefficient of $\frac{1}{(x-1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{15}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{2} \end{aligned}$$

For the pole at $x = -1$ let b be the coefficient of $\frac{1}{(x+1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{15}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{2} \end{aligned}$$

Since the order of r at ∞ is $4 > 2$ then

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0\\
\alpha_\infty^{+} &= 0\\
\alpha_\infty^{-} &= 1
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{15}{(x^2-1)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
1	2	0	$\frac{5}{2}$	$-\frac{3}{2}$
-1	2	0	$\frac{5}{2}$	$-\frac{3}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = 1$ then

$$
\begin{aligned}
d &= \alpha_\infty^{-} - \left(\alpha_{c_1}^{-} + \alpha_{c_2}^{+}\right)\\
&= 1 - (1)\\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x-c_1}\right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{+}}{x-c_2}\right) + (-)[\sqrt{r}]_\infty\\
&= -\frac{3}{2\,(x-1)} + \frac{5}{2\,(x+1)} + (-)\,(0)\\
&= -\frac{3}{2\,(x-1)} + \frac{5}{2\,(x+1)}\\
&= \frac{x-4}{x^2-1}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{3}{2(x-1)} + \frac{5}{2(x+1)}\right)(0) + \left(\left(\frac{3}{2(x-1)^2} - \frac{5}{2(x+1)^2}\right) + \left(-\frac{3}{2(x-1)} + \frac{5}{2(x+1)}\right)^2 - \left(\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= \mathrm{e}^{\int \left(-\frac{3}{2(x-1)} + \frac{5}{2(x+1)}\right) dx} \\ &= \frac{(x+1)^{5/2}}{(x-1)^{3/2}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-6x}{x^2-1} \, dx} \\ &= z_1 e^{\frac{3\ln(x-1)}{2} + \frac{3\ln(x+1)}{2}} \\ &= z_1 \left((x-1)^{3/2} (x+1)^{3/2}\right) \end{aligned}$$

Which simplifies to

$$y_1 = (x+1)^4$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-6x}{x^2-1} \, dx}}{(y_1)^2} \, dx \\ &= y_1 \int \frac{e^{3\ln(x-1)+3\ln(x+1)}}{(y_1)^2} \, dx \\ &= y_1 \left(-\frac{x(x^2+1)\,\mathrm{e}^{3\ln(x-1)+3\ln(x+1)}}{(x+1)^7 (x-1)^3}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left((x+1)^4\right) + c_2 \left((x+1)^4 \left(-\frac{x(x^2+1)\,\mathrm{e}^{3\ln(x-1)+3\ln(x+1)}}{(x+1)^7 (x-1)^3}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$(x^2-1)\left(\frac{d^2}{dx^2}y(x)\right)-6x\left(\frac{d}{dx}y(x)\right)+12y(x)=0$

- Highest derivative means the order of the ODE is 2

$\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

$\frac{d^2}{dx^2}y(x)=-\frac{12y(x)}{x^2-1}+\frac{6\left(\frac{d}{dx}y(x)\right)x}{x^2-1}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

$\frac{d^2}{dx^2}y(x)-\frac{6\left(\frac{d}{dx}y(x)\right)x}{x^2-1}+\frac{12y(x)}{x^2-1}=0$

□ Check to see if x_0 is a regular singular point

 ◦ Define functions

 $\left[P_2(x)=-\frac{6x}{x^2-1},P_3(x)=\frac{12}{x^2-1}\right]$

 ◦ $(x+1)\cdot P_2(x)$ is analytic at $x=-1$

 $\left((x+1)\cdot P_2(x)\right)\bigg|_{x=-1}=-3$

 ◦ $(x+1)^2\cdot P_3(x)$ is analytic at $x=-1$

 $\left((x+1)^2\cdot P_3(x)\right)\bigg|_{x=-1}=0$

 ◦ $x=-1$is a regular singular point

Check to see if x_0 is a regular singular point

$x_0=-1$

- Multiply by denominators

$(x^2-1)\left(\frac{d^2}{dx^2}y(x)\right)-6x\left(\frac{d}{dx}y(x)\right)+12y(x)=0$

- Change variables using $x=u-1$ so that the regular singular point is at $u=0$

$(u^2-2u)\left(\frac{d^2}{du^2}y(u)\right)+(-6u+6)\left(\frac{d}{du}y(u)\right)+12y(u)=0$

- Assume series solution for $y(u)$

$y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

□ Rewrite ODE with series expansions

 ◦ Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$

 $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,u^{k+r-1+m}$

 ◦ Shift index using $k->k+1-m$

 $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,u^{k+r}$

 ◦ Convert $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m=1..2$

 $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)(k+r-1)\,u^{k+r-2+m}$

 ◦ Shift index using $k->k+2-m$

 $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=-2+m}^{\infty}a_{k+2-m}(k+2-m+r)(k+1-m+r)\,u^{k+r}$

Rewrite ODE with series expansions

$-2a_0r(-4+r)\,u^{-1+r}+\left(\sum_{k=0}^{\infty}\left(-2a_{k+1}(k+1+r)(k+r-3)+a_k(k+r-3)(k+r-4)\right)u^{k+r}\right)=$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$-2r(-4+r)=0$

- Values of r that satisfy the indicial equation

  $r\in\{0,4\}$
- Each term in the series must be 0, giving the recursion relation

  $((-2k-2r-2)\,a_{k+1}+a_k(k+r-4))\,(k+r-3)=0$
- Recursion relation that defines series solution to ODE

  $a_{k+1}=\frac{a_k(k+r-4)}{2(k+1+r)}$
- Recursion relation for $r=0$; series terminates at $k=4$

  $a_{k+1}=\frac{a_k(k-4)}{2(k+1)}$
- Apply recursion relation for $k=0$

  $a_1=-2a_0$
- Apply recursion relation for $k=1$

  $a_2=-\frac{3a_1}{4}$
- Express in terms of a_0

  $a_2=\frac{3a_0}{2}$
- Apply recursion relation for $k=2$

  $a_3=-\frac{a_2}{3}$
- Express in terms of a_0

  $a_3=-\frac{a_0}{2}$
- Apply recursion relation for $k=3$

  $a_4=-\frac{a_3}{8}$
- Express in terms of a_0

  $a_4=\frac{a_0}{16}$
- Terminating series solution of the ODE for $r=0$. Use reduction of order to find the second li

  $y(u)=a_0\cdot\left(1-2u+\frac{3}{2}u^2-\frac{1}{2}u^3+\frac{1}{16}u^4\right)$
- Revert the change of variables $u=x+1$

  $\left[y(x)=\frac{a_0(x-1)^4}{16}\right]$
- Recursion relation for $r=4$

  $a_{k+1}=\frac{a_k k}{2(k+5)}$
- Solution for $r=4$

  $\left[y(u)=\sum_{k=0}^{\infty}a_k u^{k+4},a_{k+1}=\frac{a_k k}{2(k+5)}\right]$
- Revert the change of variables $u=x+1$

  $\left[y(x)=\sum_{k=0}^{\infty}a_k(x+1)^{k+4},a_{k+1}=\frac{a_k k}{2(k+5)}\right]$
- Combine solutions and rename parameters

  $\left[y(x)=\frac{a_0(x-1)^4}{16}+\left(\sum_{k=0}^{\infty}b_k(x+1)^{4+k}\right),b_{k+1}=\frac{b_k k}{2(5+k)}\right]$

2.1.224 Problem 227

Internal problem ID [9396]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 227
Date solved : `Monday, January 27, 2025 at 06:02:18 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$y'' + xy' + (2+x)\, y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.277 (sec)

Writing the ode as

$$y'' + xy' + (2+x)\, y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= x \\ C &= 2+x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 - 4x - 6}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2 - 4x - 6 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{1}{4}x^2 - x - \frac{3}{2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\,e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.430: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 2 \\ &= -2 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x}{2} - 1 - \frac{5}{2x} - \frac{5}{x^2} - \frac{65}{4x^3} - \frac{115}{2x^4} - \frac{885}{4x^5} - \frac{1785}{2x^6} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v=1$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= \frac{x}{2} - 1 \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}x^2 - x + 1$$

This shows that the coefficient of 1 in the above is 1. Now we need to find the coefficient of 1 in r. How this is done depends on if $v=0$ or not. Since $v=1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 - 4x - 6}{4} \\ &= Q + \frac{R}{4} \\ &= \left(\frac{1}{4}x^2 - x - \frac{3}{2}\right) + (0) \\ &= \frac{1}{4}x^2 - x - \frac{3}{2} \end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is $-\frac{3}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{3}{2}\right) - (1) \\ &= -\frac{5}{2} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{x}{2} - 1 \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{5}{2}}{\frac{1}{2}} - 1\right) &&= -3 \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{5}{2}}{\frac{1}{2}} - 1\right) &&= 2 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{1}{4}x^2 - x - \frac{3}{2}$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-2	$\frac{x}{2} - 1$	-3	2

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 2$, and since there are no poles then

$$\begin{aligned} d &= \alpha_\infty^- \\ &= 2 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= (-)[\sqrt{r}]_\infty \\ &= 0 + (-)\left(\frac{x}{2} - 1\right) \\ &= 1 - \frac{x}{2} \\ &= 1 - \frac{x}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 2$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\,p = 0 \tag{1A}$$

Let

$$p(x) = x^2 + a_1 x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (2) + 2\left(1 - \frac{x}{2}\right)(2x + a_1) + \left(\left(-\frac{1}{2}\right) + \left(1 - \frac{x}{2}\right)^2 - \left(\frac{1}{4}x^2 - x - \frac{3}{2}\right)\right) &= 0 \\ (2 + x)\,a_1 + 4x + 2a_0 + 2 &= 0 \end{aligned}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 3, a_1 = -4\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^2 - 4x + 3$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega\,dx} \\ &= (x^2 - 4x + 3)\,e^{\int (1 - \frac{x}{2})dx} \\ &= (x^2 - 4x + 3)\,e^{x - \frac{1}{4}x^2} \\ &= (x^2 - 4x + 3)\,e^{-\frac{x(-4+x)}{4}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{x}{1}\,dx} \\ &= z_1 e^{-\frac{x^2}{4}} \\ &= z_1\left(e^{-\frac{x^2}{4}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \left(x^2 - 4x + 3\right) e^{-\frac{x(-2+x)}{2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{x}{1}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-\frac{x^2}{2}}}{(y_1)^2}\, dx \\ &= y_1 \left(\int \frac{e^{-\frac{x^2}{2}} e^{x(-2+x)}}{(x^2 - 4x + 3)^2} dx \right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\left(x^2 - 4x + 3\right) e^{-\frac{x(-2+x)}{2}} \right) + c_2 \left(\left(x^2 - 4x + 3\right) e^{-\frac{x(-2+x)}{2}} \left(\int \frac{e^{-\frac{x^2}{2}} e^{x(-2+x)}}{(x^2 - 4x + 3)^2} dx \right) \right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve
$\frac{d^2}{dx^2}y(x) + x\left(\frac{d}{dx}y(x)\right) + (x+2)\, y(x) = 0$

- Highest derivative means the order of the ODE is 2
  $\frac{d^2}{dx^2}y(x)$
- Assume series solution for $y(x)$
  $y(x) = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite ODE with series expansions

- ○ Convert $x^m \cdot y(x)$ to series expansion for $m = 0..1$
  $x^m \cdot y(x) = \sum_{k=\max(0,-m)}^{\infty} a_k x^{k+m}$
- ○ Shift index using $k- > k - m$
  $x^m \cdot y(x) = \sum_{k=\max(0,-m)+m}^{\infty} a_{k-m} x^k$
- ○ Convert $x \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion
  $x \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k k\, x^k$
- ○ Convert $\frac{d^2}{dx^2}y(x)$ to series expansion
  $\frac{d^2}{dx^2}y(x) = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$
- ○ Shift index using $k- > k + 2$

$$\frac{d^2}{dx^2}y(x) = \sum_{k=0}^{\infty} a_{k+2}(k+2)(k+1)\,x^k$$

Rewrite ODE with series expansions

$$2a_2 + 2a_0 + \left(\sum_{k=1}^{\infty} \left(a_{k+2}(k+2)(k+1) + a_k(k+2) + a_{k-1}\right) x^k\right) = 0$$

- Each term must be 0

  $$2a_2 + 2a_0 = 0$$

- Each term in the series must be 0, giving the recursion relation

  $$(k^2 + 3k + 2)\,a_{k+2} + a_k k + 2a_k + a_{k-1} = 0$$

- Shift index using $k- >k+1$

  $$\left((k+1)^2 + 3k + 5\right) a_{k+3} + a_{k+1}(k+1) + 2a_{k+1} + a_k = 0$$

- Recursion relation that defines the series solution to the ODE

  $$\left[y(x) = \sum_{k=0}^{\infty} a_k x^k, a_{k+3} = -\frac{k a_{k+1} + a_k + 3a_{k+1}}{k^2 + 5k + 6}, 2a_2 + 2a_0 = 0\right]$$

2.1.225 Problem 228

Internal problem ID [9397]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 228
Date solved : `Monday, January 27, 2025 at 06:02:18 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$\left(2x^2+1\right)y''+7xy'+2y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.335 (sec)

Writing the ode as

$$\left(2x^2+1\right)y''+7xy'+2y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A&=2x^2+1\\ B&=7x\\ C&=2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r&=\frac{s}{t}\\ &=\frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{5x^2+6}{4\left(2x^2+1\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s&=5x^2+6\\ t&=4\left(2x^2+1\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{5x^2+6}{4\left(2x^2+1\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.432: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(2x^2 + 1)^2$. There is a pole at $x = \frac{i\sqrt{2}}{2}$ of order 2. There is a pole at $x = -\frac{i\sqrt{2}}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{7}{64\left(x - \frac{i\sqrt{2}}{2}\right)^2} - \frac{7}{64\left(x + \frac{i\sqrt{2}}{2}\right)^2} - \frac{17i\sqrt{2}}{64\left(x - \frac{i\sqrt{2}}{2}\right)} + \frac{17i\sqrt{2}}{64\left(x + \frac{i\sqrt{2}}{2}\right)}$$

For the pole at $x = \frac{i\sqrt{2}}{2}$ let b be the coefficient of $\frac{1}{\left(x - \frac{i\sqrt{2}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{7}{64}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{7}{8} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{8} \end{aligned}$$

For the pole at $x = -\frac{i\sqrt{2}}{2}$ let b be the coefficient of $\frac{1}{\left(x+\frac{i\sqrt{2}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{7}{64}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0\\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{8}\\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{8}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = \frac{5x^2+6}{4\left(2x^2+1\right)^2}
$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{5}{16}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0\\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{4}\\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{4}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{5x^2+6}{4\left(2x^2+1\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
$\frac{i\sqrt{2}}{2}$	2	0	$\frac{7}{8}$	$\frac{1}{8}$
$-\frac{i\sqrt{2}}{2}$	2	0	$\frac{7}{8}$	$\frac{1}{8}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{5}{4}$	$-\frac{1}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{5}{4}$ then

$$
\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^- + \alpha_{c_2}^-\right)\\
&= \frac{5}{4} - \left(\frac{1}{4}\right)\\
&= 1
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

Substituting the above values in the above results in

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{-}}{x - c_2}\right) + (+)[\sqrt{r}]_{\infty} \\
&= \frac{1}{8x - 4i\sqrt{2}} + \frac{1}{8x + 4i\sqrt{2}} + (0) \\
&= \frac{1}{8x - 4i\sqrt{2}} + \frac{1}{8x + 4i\sqrt{2}} \\
&= \frac{x}{4x^2 + 2}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = x + a_0 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(0) + 2\left(\frac{1}{8x - 4i\sqrt{2}} + \frac{1}{8x + 4i\sqrt{2}}\right)(1) + \left(\left(-\frac{1}{8\left(x - \frac{i\sqrt{2}}{2}\right)^2} - \frac{1}{8\left(x + \frac{i\sqrt{2}}{2}\right)^2}\right) + \left(\frac{1}{8x - 4i\sqrt{2}} + \frac{1}{8x + 4
$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$
\{a_0 = 0\}
$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$
p(x) = x
$$

Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= (x)\, e^{\int \left(\frac{1}{8x - 4i\sqrt{2}} + \frac{1}{8x + 4i\sqrt{2}}\right) dx} \\
&= (x) \left(\left(i\sqrt{2} - 2x\right)\left(2x + i\sqrt{2}\right)\right)^{1/8} \\
&= x\left(-4x^2 - 2\right)^{1/8}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{7x}{2x^2 + 1} \, dx} \\
&= z_1 e^{-\frac{7 \ln\left(2x^2 + 1\right)}{8}} \\
&= z_1 \left(\frac{1}{\left(2x^2 + 1\right)^{7/8}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{2^{7/8} x \left(-4x^2 - 2\right)^{1/8}}{\left(4x^2 + 2\right)^{7/8}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{7x}{2x^2+1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{-\frac{7\ln(2x^2+1)}{4}}}{(y_1)^2}\,dx \\ &= y_1 \left(\int \frac{2^{1/4}(4x^2+2)^{7/4}}{4\,(2x^2+1)^{7/4}\,x^2\,(-4x^2-2)^{1/4}}dx\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\frac{2^{7/8}x(-4x^2-2)^{1/8}}{(4x^2+2)^{7/8}}\right) + c_2 \left(\frac{2^{7/8}x(-4x^2-2)^{1/8}}{(4x^2+2)^{7/8}}\left(\int \frac{2^{1/4}(4x^2+2)^{7/4}}{4\,(2x^2+1)^{7/4}\,x^2\,(-4x^2-2)^{1/4}}dx\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

2.1.226 Problem 229

Internal problem ID [9398]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 229
Date solved : `Monday, January 27, 2025 at 06:02:19 PM`
CAS classification : `[_Lienard]`

Solve

$$4y'' + xy' + 4y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.249 (sec)

Writing the ode as

$$4y'' + xy' + 4y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4 \\ B &= x \\ C &= 4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 - 56}{64} \tag{6}$$

Comparing the above to (5) shows that

$$s = x^2 - 56$$
$$t = 64$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2}{64} - \frac{7}{8}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.433: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 2 \\ &= -2 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x}{8} - \frac{7}{2x} - \frac{49}{x^3} - \frac{1372}{x^5} - \frac{48020}{x^7} - \frac{1882384}{x^9} - \frac{79060128}{x^{11}} - \frac{3478645632}{x^{13}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{8}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= \frac{x}{8} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{x^2}{64}$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 - 56}{64} \\ &= Q + \frac{R}{64} \\ &= \left(\frac{x^2}{64} - \frac{7}{8}\right) + (0) \\ &= \frac{x^2}{64} - \frac{7}{8} \end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is $-\frac{7}{8}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{7}{8}\right) - (0) \\ &= -\frac{7}{8} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{x}{8} \\ \alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{7}{8}}{\frac{1}{8}} - 1\right) &&= -4 \\ \alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{7}{8}}{\frac{1}{8}} - 1\right) &&= 3 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2}{64} - \frac{7}{8}$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
-2	$\frac{x}{8}$	-4	3

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 3$, and since there are no poles then

$$\begin{aligned} d &= \alpha_\infty^- \\ &= 3 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= (-)[\sqrt{r}]_\infty \\ &= 0 + (-)\left(\frac{x}{8}\right) \\ &= -\frac{x}{8} \\ &= -\frac{x}{8} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=3$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}$$

Let

$$p(x) = x^3 + a_2x^2 + a_1x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (6x+2a_2) + 2\left(-\frac{x}{8}\right)\left(3x^2 + 2xa_2 + a_1\right) + \left(\left(-\frac{1}{8}\right) + \left(-\frac{x}{8}\right)^2 - \left(\frac{x^2}{64} - \frac{7}{8}\right)\right) &= 0 \\ 6x + 2a_2 + \frac{1}{4}a_2x^2 + \frac{1}{2}a_1x + \frac{3}{4}a_0 &= 0 \end{aligned}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 0, a_1 = -12, a_2 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^3 - 12x$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= pe^{\int \omega\, dx} \\ &= \left(x^3 - 12x\right)e^{\int -\frac{x}{8}dx} \\ &= \left(x^3 - 12x\right)e^{-\frac{x^2}{16}} \\ &= x\left(x^2 - 12\right)e^{-\frac{x^2}{16}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{x}{4}\, dx} \\ &= z_1 e^{-\frac{x^2}{16}} \\ &= z_1\left(e^{-\frac{x^2}{16}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-\frac{x^2}{8}} x(x^2 - 12)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{x}{4}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-\frac{x^2}{8}}}{(y_1)^2}\, dx \\ &= y_1 \left(\int \frac{\mathrm{e}^{\frac{x^2}{8}}}{x^2 (x^2 - 12)^2} dx \right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\mathrm{e}^{-\frac{x^2}{8}} x(x^2 - 12) \right) + c_2 \left(\mathrm{e}^{-\frac{x^2}{8}} x(x^2 - 12) \left(\int \frac{\mathrm{e}^{\frac{x^2}{8}}}{x^2 (x^2 - 12)^2} dx \right) \right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$4 \frac{d^2}{dx^2} y(x) + x \left(\frac{d}{dx} y(x) \right) + 4y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2} y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2} y(x) = -\frac{x \left(\frac{d}{dx} y(x) \right)}{4} - y(x)$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2} y(x) + \frac{x \left(\frac{d}{dx} y(x) \right)}{4} + y(x) = 0$

- Multiply by denominators

  $4 \frac{d^2}{dx^2} y(x) + x \left(\frac{d}{dx} y(x) \right) + 4y(x) = 0$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite DE with series expansions

  - Convert $x \cdot \left(\frac{d}{dx} y(x) \right)$ to series expansion

    $x \cdot \left(\frac{d}{dx} y(x) \right) = \sum_{k=0}^{\infty} a_k k\, x^k$

  - Convert $\frac{d^2}{dx^2} y(x)$ to series expansion

    $\frac{d^2}{dx^2} y(x) = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$

  - Shift index using $k- >k+2$

$\frac{d^2}{dx^2}y(x) = \sum_{k=0}^{\infty} a_{k+2}(k+2)(k+1)\,x^k$

Rewrite DE with series expansions

$\sum_{k=0}^{\infty} \left(4a_{k+2}(k+2)(k+1) + a_k(k+4)\right) x^k = 0$

- Each term in the series must be 0, giving the recursion relation

  $4(k^2+3k+2)\,a_{k+2} + a_k(k+4) = 0$
- Recursion relation that defines the series solution to the ODE

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^k, a_{k+2} = -\frac{a_k(k+4)}{4(k^2+3k+2)}\right]$

2.1.227 Problem 230

Internal problem ID [9399]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 230
Date solved : `Monday, January 27, 2025 at 06:02:20 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$y'' + xy' - 4y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.217 (sec)

Writing the ode as

$$y'' + xy' - 4y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= x \\ C &= -4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 + 18}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2 + 18 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2}{4} + \frac{9}{2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.435: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 2 \\ &= -2 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x}{2} + \frac{9}{2x} - \frac{81}{4x^3} + \frac{729}{4x^5} - \frac{32805}{16x^7} + \frac{413343}{16x^9} - \frac{11160261}{32x^{11}} + \frac{157837977}{32x^{13}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= \frac{x}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{x^2}{4}$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 + 18}{4} \\ &= Q + \frac{R}{4} \\ &= \left(\frac{x^2}{4} + \frac{9}{2}\right) + (0) \\ &= \frac{x^2}{4} + \frac{9}{2} \end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is $\frac{9}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(\frac{9}{2}\right) - (0) \\ &= \frac{9}{2} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{x}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{\frac{9}{2}}{\frac{1}{2}} - 1\right) &= 4 \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{\frac{9}{2}}{\frac{1}{2}} - 1\right) &= -5 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2}{4} + \frac{9}{2}$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-2	$\frac{x}{2}$	4	-5

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = 4$, and since there are no poles, then

$$\begin{aligned} d &= \alpha_\infty^+ \\ &= 4 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= (+)[\sqrt{r}]_\infty \\ &= 0 + \left(\frac{x}{2}\right) \\ &= \frac{x}{2} \\ &= \frac{x}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 4$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = x^4 + a_3x^3 + a_2x^2 + a_1x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(12x^2 + 6xa_3 + 2a_2) + 2\left(\frac{x}{2}\right)(4x^3 + 3x^2a_3 + 2xa_2 + a_1) + \left(\left(\frac{1}{2}\right) + \left(\frac{x}{2}\right)^2 - \left(\frac{x^2}{4} + \frac{9}{2}\right)\right) = 0$$

$$-a_3x^3 + (-2a_2 + 12)\,x^2 + (-3a_1 + 6a_3)\,x - 4a_0 + 2a_2 = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 3, a_1 = 0, a_2 = 6, a_3 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^4 + 6x^2 + 3$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= pe^{\int \omega\, dx} \\ &= (x^4 + 6x^2 + 3)\, e^{\int \frac{x}{2} dx} \\ &= (x^4 + 6x^2 + 3)\, e^{\frac{x^2}{4}} \\ &= (x^4 + 6x^2 + 3)\, e^{\frac{x^2}{4}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{x}{1}\, dx} \\ &= z_1 e^{-\frac{x^2}{4}} \\ &= z_1 \left(e^{-\frac{x^2}{4}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = x^4 + 6x^2 + 3$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{x}{1}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-\frac{x^2}{2}}}{(y_1)^2}\, dx \\ &= y_1 \left(\int \frac{e^{-\frac{x^2}{2}}}{(x^4 + 6x^2 + 3)^2} dx \right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 (x^4 + 6x^2 + 3) + c_2 \left(x^4 + 6x^2 + 3 \left(\int \frac{e^{-\frac{x^2}{2}}}{(x^4 + 6x^2 + 3)^2} dx \right) \right) \end{aligned}$$

Will add steps showing solving for IC soon.

2.1.228 Problem 231

Internal problem ID [9400]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 231
Date solved : `Monday, January 27, 2025 at 06:02:20 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$4xy'' - xy' + 2y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.226 (sec)

Writing the ode as

$$4xy'' - xy' + 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4x \\ B &= -x \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x - 32}{64x} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x - 32 \\ t &= 64x \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x - 32}{64x}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.436: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 1 - 1 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 64x$. There is a pole at $x = 0$ of order 1. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 1. For the pole at $x = 0$ of order 1 then

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= 1 \\ \alpha_c^- &= 1 \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{8} - \frac{2}{x} - \frac{16}{x^2} - \frac{256}{x^3} - \frac{5120}{x^4} - \frac{114688}{x^5} - \frac{2752512}{x^6} - \frac{69206016}{x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{8}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{8} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{64}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x-32}{64x} \\ &= Q + \frac{R}{64x} \\ &= \left(\frac{1}{64}\right) + \left(-\frac{1}{2x}\right) \\ &= \frac{1}{64} - \frac{1}{2x} \end{aligned}$$

Since the degree of t is 1, then we see that the coefficient of the term 1 in the remainder R is -32. Dividing this by leading coefficient in t which is 64 gives $-\frac{1}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{1}{2}\right) - (0) \\ &= -\frac{1}{2} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{8} \\ \alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-\frac{1}{2}}{\frac{1}{8}} - 0\right) &= -2 \\ \alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-\frac{1}{2}}{\frac{1}{8}} - 0\right) &= 2 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x-32}{64x}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	1	0	0	1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{8}$	-2	2

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 2$ then

$$\begin{aligned} d &= \alpha_\infty^- - (\alpha_{c_1}^-) \\ &= 2 - (1) \\ &= 1 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{1}{x} + (-)\left(\frac{1}{8}\right) \\ &= \frac{1}{x} - \frac{1}{8} \\ &= \frac{1}{x} - \frac{1}{8} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{x} - \frac{1}{8}\right)(1) + \left(\left(-\frac{1}{x^2}\right) + \left(\frac{1}{x} - \frac{1}{8}\right)^2 - \left(\frac{x-32}{64x}\right)\right) = 0$$

$$\frac{8 + a_0}{4x} = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = -8\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = -8 + x$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega\, dx} \\ &= (-8 + x)\, e^{\int \left(\frac{1}{x} - \frac{1}{8}\right) dx} \\ &= (-8 + x)\, e^{-\frac{x}{8} + \ln(x)} \\ &= (-8 + x)\, x\, e^{-\frac{x}{8}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-x}{4x}\,dx} \\ &= z_1 e^{\frac{x}{8}} \\ &= z_1\left(\mathrm{e}^{\frac{x}{8}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = (-8+x)\,x$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-x}{4x}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{\frac{x}{4}}}{(y_1)^2}\,dx \\ &= y_1\left(-\frac{\mathrm{e}^{\frac{x}{4}}}{64x} - \frac{\mathrm{Ei}_1\left(-\frac{x}{4}\right)}{128} - \frac{\mathrm{e}^{\frac{x}{4}}}{256\left(-2+\frac{x}{4}\right)}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1((-8+x)\,x) + c_2\left((-8+x)\,x\left(-\frac{\mathrm{e}^{\frac{x}{4}}}{64x} - \frac{\mathrm{Ei}_1\left(-\frac{x}{4}\right)}{128} - \frac{\mathrm{e}^{\frac{x}{4}}}{256\left(-2+\frac{x}{4}\right)}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

2.1.229 Problem 232

Internal problem ID [9401]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 232
Date solved : `Monday, January 27, 2025 at 06:02:21 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$6x^2y'' + x(1+18x)\,y' + (1+12x)\,y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.273 (sec)

Writing the ode as

$$6x^2y'' + \left(18x^2 + x\right)y' + (1+12x)\,y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 6x^2 \\ B &= 18x^2 + x \\ C &= 1 + 12x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{324x^2 - 252x - 35}{144x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 324x^2 - 252x - 35 \\ t &= 144x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{324x^2 - 252x - 35}{144x^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.437: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 144x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{9}{4} - \frac{7}{4x} - \frac{35}{144x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{35}{144}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{12} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{5}{12} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{3}{2} - \frac{7}{12x} - \frac{7}{36x^2} - \frac{49}{648x^3} - \frac{245}{5832x^4} - \frac{343}{13122x^5} - \frac{66199}{3779136x^6} - \frac{837949}{68024448x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{3}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{3}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{9}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{324x^2 - 252x - 35}{144x^2} \\ &= Q + \frac{R}{144x^2} \\ &= \left(\frac{9}{4}\right) + \left(\frac{-252x - 35}{144x^2}\right) \\ &= \frac{9}{4} + \frac{-252x - 35}{144x^2} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is -252. Dividing this by leading coefficient in t which is 144 gives $-\frac{7}{4}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{7}{4}\right) - (0) \\ &= -\frac{7}{4} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{3}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) = \frac{1}{2}\left(\frac{-\frac{7}{4}}{\frac{3}{2}} - 0\right) = -\frac{7}{12} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) = \frac{1}{2}\left(-\frac{-\frac{7}{4}}{\frac{3}{2}} - 0\right) = \frac{7}{12} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{324x^2 - 252x - 35}{144x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{7}{12}$	$\frac{5}{12}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{3}{2}$	$-\frac{7}{12}$	$\frac{7}{12}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{7}{12}$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^+\right) \\ &= \frac{7}{12} - \left(\frac{7}{12}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{7}{12x} + (-)\left(\frac{3}{2}\right) \\ &= \frac{7}{12x} - \frac{3}{2} \\ &= \frac{7}{12x} - \frac{3}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{gathered} (0) + 2\left(\frac{7}{12x} - \frac{3}{2}\right)(0) + \left(\left(-\frac{7}{12x^2}\right) + \left(\frac{7}{12x} - \frac{3}{2}\right)^2 - \left(\frac{324x^2 - 252x - 35}{144x^2}\right)\right) = 0 \\ 0 = 0 \end{gathered}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= e^{\int \left(\frac{7}{12x} - \frac{3}{2}\right) dx} \\ &= x^{7/12} e^{-\frac{3x}{2}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{18x^2+x}{6x^2}\,dx} \\ &= z_1 e^{-\frac{3x}{2}-\frac{\ln(x)}{12}} \\ &= z_1\left(\frac{\mathrm{e}^{-\frac{3x}{2}}}{x^{1/12}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \sqrt{x}\,\mathrm{e}^{-3x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{18x^2+x}{6x^2}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{-3x-\frac{\ln(x)}{6}}}{(y_1)^2}\,dx \\ &= y_1\left(\int \frac{\mathrm{e}^{-3x-\frac{\ln(x)}{6}}\mathrm{e}^{6x}}{x}\,dx\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\sqrt{x}\,\mathrm{e}^{-3x}\right) + c_2\left(\sqrt{x}\,\mathrm{e}^{-3x}\left(\int \frac{\mathrm{e}^{-3x-\frac{\ln(x)}{6}}\mathrm{e}^{6x}}{x}\,dx\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$6x^2\left(\frac{d^2}{dx^2}y(x)\right) + x(1+18x)\left(\frac{d}{dx}y(x)\right) + (1+12x)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{(1+12x)y(x)}{6x^2} - \frac{(1+18x)\left(\frac{d}{dx}y(x)\right)}{6x}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x) + \frac{(1+18x)\left(\frac{d}{dx}y(x)\right)}{6x} + \frac{(1+12x)y(x)}{6x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

  $\left[P_2(x) = \frac{1+18x}{6x}, P_3(x) = \frac{1+12x}{6x^2}\right]$

- $x \cdot P_2(x)$ is analytic at $x = 0$

  $\left(x \cdot P_2(x)\right)\bigg|_{x=0} = \frac{1}{6}$
- $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = \frac{1}{6}$
- $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $6x^2\left(\frac{d^2}{dx^2}y(x)\right) + x(1+18x)\left(\frac{d}{dx}y(x)\right) + (1+12x)\,y(x) = 0$
- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

- Convert $x^m \cdot y(x)$ to series expansion for $m = 0..1$

  $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$
- Shift index using $k- >k-m$

  $x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$
- Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m = 1..2$

  $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$
- Shift index using $k- >k+1-m$

  $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$
- Convert $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

  $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(-1+3r)\,(-1+2r)\,x^r + \left(\sum_{k=1}^{\infty} \left(a_k(3k+3r-1)\,(2k+2r-1) + 6a_{k-1}(3k+3r-1)\right) x^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-1+3r)\,(-1+2r) = 0$
- Values of r that satisfy the indicial equation

  $r \in \left\{\frac{1}{2}, \frac{1}{3}\right\}$
- Each term in the series must be 0, giving the recursion relation

  $6\left(\left(k+r-\frac{1}{2}\right)a_k + 3a_{k-1}\right)\left(k-\frac{1}{3}+r\right) = 0$
- Shift index using $k- >k+1$

  $6\left(\left(k+\frac{1}{2}+r\right)a_{k+1} + 3a_k\right)\left(k+\frac{2}{3}+r\right) = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+1} = -\frac{6a_k}{2k+1+2r}$
- Recursion relation for $r = \frac{1}{2}$

  $a_{k+1} = -\frac{6a_k}{2k+2}$
- Solution for $r = \frac{1}{2}$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}, a_{k+1} = -\frac{6a_k}{2k+2}\right]$

- Recursion relation for $r = \frac{1}{3}$

  $a_{k+1} = -\frac{6a_k}{2k+\frac{5}{3}}$
- Solution for $r = \frac{1}{3}$

  $$\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{3}}, a_{k+1} = -\frac{6a_k}{2k+\frac{5}{3}}\right]$$
- Combine solutions and rename parameters

  $$\left[y(x) = \left(\sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{3}}\right), a_{k+1} = -\frac{6a_k}{2k+2}, b_{k+1} = -\frac{6b_k}{2k+\frac{5}{3}}\right]$$

2.1.230 Problem 233

Internal problem ID [9402]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 233
Date solved : `Monday, January 27, 2025 at 06:02:22 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$3x^2y'' - x(x+8)\,y' + 6y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 3.613 (sec)

Writing the ode as

$$3x^2y'' + \left(-x^2-8x\right)y' + 6y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 3x^2 \\ B &= -x^2-8x \\ C &= 6 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2+16x+40}{36x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2+16x+40 \\ t &= 36x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2+16x+40}{36x^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.439: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 36x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{36} + \frac{10}{9x^2} + \frac{4}{9x}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{10}{9}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{5}{3} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{2}{3} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{6} + \frac{4}{3x} - \frac{2}{x^2} + \frac{16}{x^3} - \frac{140}{x^4} + \frac{1312}{x^5} - \frac{12944}{x^6} + \frac{132736}{x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{6}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{6} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{36}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 + 16x + 40}{36x^2} \\ &= Q + \frac{R}{36x^2} \\ &= \left(\frac{1}{36}\right) + \left(\frac{16x + 40}{36x^2}\right) \\ &= \frac{1}{36} + \frac{16x + 40}{36x^2} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is 16. Dividing this by leading coefficient in t which is 36 gives $\frac{4}{9}$. Now b can be found.

$$\begin{aligned} b &= \left(\frac{4}{9}\right) - (0) \\ &= \frac{4}{9} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{6} \\ \alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{\frac{4}{9}}{\frac{1}{6}} - 0\right) &&= \frac{4}{3} \\ \alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{\frac{4}{9}}{\frac{1}{6}} - 0\right) &&= -\frac{4}{3} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2 + 16x + 40}{36x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{5}{3}$	$-\frac{2}{3}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{6}$	$\frac{4}{3}$	$-\frac{4}{3}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{4}{3}$ then

$$\begin{aligned} d &= \alpha_\infty^+ - (\alpha_{c_1}^-) \\ &= \frac{4}{3} - \left(-\frac{2}{3}\right) \\ &= 2 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (+)[\sqrt{r}]_\infty \\ &= -\frac{2}{3x} + \left(\frac{1}{6}\right) \\ &= -\frac{2}{3x} + \frac{1}{6} \\ &= \frac{-4+x}{6x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 2$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = x^2 + a_1 x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(2) + 2\left(-\frac{2}{3x} + \frac{1}{6}\right)(2x + a_1) + \left(\left(\frac{2}{3x^2}\right) + \left(-\frac{2}{3x} + \frac{1}{6}\right)^2 - \left(\frac{x^2+16x+40}{36x^2}\right)\right) = 0$$

$$\frac{(-a_1-2)\,x - 2a_0 - 4a_1}{3x} = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 4, a_1 = -2\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^2 - 2x + 4$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \left(x^2 - 2x + 4\right) e^{\int \left(-\frac{2}{3x} + \frac{1}{6}\right) dx} \\
&= \left(x^2 - 2x + 4\right) e^{\frac{x}{6} - \frac{2\ln(x)}{3}} \\
&= \frac{\left(x^2 - 2x + 4\right) e^{\frac{x}{6}}}{x^{2/3}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{-x^2 - 8x}{3x^2} \, dx} \\
&= z_1 e^{\frac{x}{6} + \frac{4\ln(x)}{3}} \\
&= z_1 \left(x^{4/3} e^{\frac{x}{6}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = x^{2/3} e^{\frac{x}{3}} \left(x^2 - 2x + 4\right)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-x^2 - 8x}{3x^2} \, dx}}{(y_1)^2} \, dx \\
&= y_1 \int \frac{e^{\frac{x}{3} + \frac{8\ln(x)}{3}}}{(y_1)^2} \, dx \\
&= y_1 \left(\int \frac{e^{\frac{x}{3} + \frac{8\ln(x)}{3}} e^{-\frac{2x}{3}}}{x^{4/3} \left(x^2 - 2x + 4\right)^2} dx \right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(x^{2/3} e^{\frac{x}{3}} \left(x^2 - 2x + 4\right)\right) + c_2 \left(x^{2/3} e^{\frac{x}{3}} \left(x^2 - 2x + 4\right) \left(\int \frac{e^{\frac{x}{3} + \frac{8\ln(x)}{3}} e^{-\frac{2x}{3}}}{x^{4/3} \left(x^2 - 2x + 4\right)^2} dx \right) \right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$3x^2\left(\frac{d^2}{dx^2}y(x)\right)-x(x+8)\left(\frac{d}{dx}y(x)\right)+6y(x)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x)=-\frac{2y(x)}{x^2}+\frac{(x+8)\left(\frac{d}{dx}y(x)\right)}{3x}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x)-\frac{(x+8)\left(\frac{d}{dx}y(x)\right)}{3x}+\frac{2y(x)}{x^2}=0$

□ Check to see if $x_0=0$ is a regular singular point

  ◦ Define functions

  $\left[P_2(x)=-\frac{x+8}{3x},P_3(x)=\frac{2}{x^2}\right]$

  ◦ $x\cdot P_2(x)$ is analytic at $x=0$

  $\left.(x\cdot P_2(x))\right|_{x=0}=-\frac{8}{3}$

  ◦ $x^2\cdot P_3(x)$ is analytic at $x=0$

  $\left.(x^2\cdot P_3(x))\right|_{x=0}=2$

  ◦ $x=0$is a regular singular point

  Check to see if $x_0=0$ is a regular singular point

  $x_0=0$

- Multiply by denominators

  $3x^2\left(\frac{d^2}{dx^2}y(x)\right)-x(x+8)\left(\frac{d}{dx}y(x)\right)+6y(x)=0$

- Assume series solution for $y(x)$

  $y(x)=\sum_{k=0}^{\infty}a_kx^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $x^m\cdot\left(\frac{d}{dx}y(x)\right)$ to series expansion for $m=1..2$

  $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,x^{k+r-1+m}$

  ◦ Shift index using $k->k+1-m$

  $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,x^{k+r}$

  ◦ Convert $x^2\cdot\left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

  $x^2\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(-2+3r)\,(-3+r)\,x^r+\left(\sum_{k=1}^{\infty}\left(a_k(3k+3r-2)\,(k+r-3)-a_{k-1}(k+r-1)\right)x^{k+r}\right)=0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-2+3r)\,(-3+r)=0$

- Values of r that satisfy the indicial equation

  $r\in\left\{3,\frac{2}{3}\right\}$

- Each term in the series must be 0, giving the recursion relation

  $3\left(k+r-\frac{2}{3}\right)(k+r-3)\,a_k-a_{k-1}(k+r-1)=0$

- Shift index using $k->k+1$

$3\left(k+\frac{1}{3}+r\right)(k-2+r)\,a_{k+1}-a_k(k+r)=0$

- Recursion relation that defines series solution to ODE

$a_{k+1}=\frac{a_k(k+r)}{(3k+1+3r)(k-2+r)}$

- Recursion relation for $r=3$

$a_{k+1}=\frac{a_k(k+3)}{(3k+10)(k+1)}$

- Solution for $r=3$

$\left[y(x)=\sum_{k=0}^{\infty} a_k x^{k+3}, a_{k+1}=\frac{a_k(k+3)}{(3k+10)(k+1)}\right]$

- Recursion relation for $r=\frac{2}{3}$

$a_{k+1}=\frac{a_k\left(k+\frac{2}{3}\right)}{(3k+3)\left(k-\frac{4}{3}\right)}$

- Solution for $r=\frac{2}{3}$

$\left[y(x)=\sum_{k=0}^{\infty} a_k x^{k+\frac{2}{3}}, a_{k+1}=\frac{a_k\left(k+\frac{2}{3}\right)}{(3k+3)\left(k-\frac{4}{3}\right)}\right]$

- Combine solutions and rename parameters

$\left[y(x)=\left(\sum_{k=0}^{\infty} a_k x^{k+3}\right)+\left(\sum_{k=0}^{\infty} b_k x^{k+\frac{2}{3}}\right), a_{k+1}=\frac{a_k(k+3)}{(3k+10)(k+1)}, b_{k+1}=\frac{b_k\left(k+\frac{2}{3}\right)}{(3k+3)\left(k-\frac{4}{3}\right)}\right]$

2.1.231 Problem 234

Internal problem ID [9403]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 234
Date solved : `Monday, January 27, 2025 at 06:02:26 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$2x^2y'' - x(1+2x)\,y' + 2(4x-1)\,y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.737 (sec)

Writing the ode as

$$2x^2y'' + \left(-2x^2 - x\right)y' + (8x-2)\,y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2x^2 \\ B &= -2x^2 - x \\ C &= 8x - 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{4x^2 - 60x + 21}{16x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 4x^2 - 60x + 21 \\ t &= 16x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{4x^2 - 60x + 21}{16x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.441: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} + \frac{21}{16x^2} - \frac{15}{4x}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{21}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{7}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{3}{4} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} - \frac{15}{4x} - \frac{51}{4x^2} - \frac{765}{8x^3} - \frac{3519}{4x^4} - \frac{144585}{16x^5} - \frac{6358527}{64x^6} - \frac{146409525}{128x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{4x^2 - 60x + 21}{16x^2} \\ &= Q + \frac{R}{16x^2} \\ &= \left(\frac{1}{4}\right) + \left(\frac{-60x + 21}{16x^2}\right) \\ &= \frac{1}{4} + \frac{-60x + 21}{16x^2} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is -60. Dividing this by leading coefficient in t which is 16 gives $-\frac{15}{4}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{15}{4}\right) - (0) \\ &= -\frac{15}{4} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{2} \\ \alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{15}{4}}{\frac{1}{2}} - 0\right) &&= -\frac{15}{4} \\ \alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{15}{4}}{\frac{1}{2}} - 0\right) &&= \frac{15}{4} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{4x^2 - 60x + 21}{16x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{7}{4}$	$-\frac{3}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	$-\frac{15}{4}$	$\frac{15}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{15}{4}$ then

$$\begin{aligned} d &= \alpha_\infty^- - (\alpha_{c_1}^+) \\ &= \frac{15}{4} - \left(\frac{7}{4}\right) \\ &= 2 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{7}{4x} + (-)\left(\frac{1}{2}\right) \\ &= \frac{7}{4x} - \frac{1}{2} \\ &= \frac{7}{4x} - \frac{1}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 2$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x^2 + a_1 x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(2) + 2\left(\frac{7}{4x} - \frac{1}{2}\right)(2x + a_1) + \left(\left(-\frac{7}{4x^2}\right) + \left(\frac{7}{4x} - \frac{1}{2}\right)^2 - \left(\frac{4x^2 - 60x + 21}{16x^2}\right)\right) = 0$$

$$\frac{2(9 + a_1)\,x + 4a_0 + 7a_1}{2x} = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\left\{a_0 = \frac{63}{4}, a_1 = -9\right\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^2 - 9x + \frac{63}{4}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \left(x^2 - 9x + \frac{63}{4}\right) e^{\int \left(\frac{7}{4x} - \frac{1}{2}\right) dx} \\
&= \left(x^2 - 9x + \frac{63}{4}\right) e^{-\frac{x}{2} + \frac{7\ln(x)}{4}} \\
&= \frac{(4x^2 - 36x + 63)\, x^{7/4} e^{-\frac{x}{2}}}{4}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{-2x^2 - x}{2x^2} \, dx} \\
&= z_1 e^{\frac{x}{2} + \frac{\ln(x)}{4}} \\
&= z_1 \left(x^{1/4} e^{\frac{x}{2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = x^4 - 9x^3 + \frac{63}{4} x^2$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-2x^2 - x}{2x^2} \, dx}}{(y_1)^2} \, dx \\
&= y_1 \int \frac{e^{x + \frac{\ln(x)}{2}}}{(y_1)^2} \, dx \\
&= y_1 \left(\int \frac{e^{x + \frac{\ln(x)}{2}}}{\left(x^4 - 9x^3 + \frac{63}{4}x^2\right)^2} dx \right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(x^4 - 9x^3 + \frac{63}{4}x^2\right) + c_2 \left(x^4 - 9x^3 + \frac{63}{4}x^2 \left(\int \frac{e^{x + \frac{\ln(x)}{2}}}{\left(x^4 - 9x^3 + \frac{63}{4}x^2\right)^2} dx \right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$2x^2\left(\frac{d^2}{dx^2}y(x)\right) - x(2x+1)\left(\frac{d}{dx}y(x)\right) + 2(4x-1)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{(4x-1)y(x)}{x^2} + \frac{(2x+1)\left(\frac{d}{dx}y(x)\right)}{2x}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x) - \frac{(2x+1)\left(\frac{d}{dx}y(x)\right)}{2x} + \frac{(4x-1)y(x)}{x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  - Define functions

    $\left[P_2(x) = -\frac{2x+1}{2x}, P_3(x) = \frac{4x-1}{x^2}\right]$

  - $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left(x \cdot P_2(x)\right)\Big|_{x=0} = -\frac{1}{2}$

  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $\left(x^2 \cdot P_3(x)\right)\Big|_{x=0} = -1$

  - $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $2x^2\left(\frac{d^2}{dx^2}y(x)\right) - x(2x+1)\left(\frac{d}{dx}y(x)\right) + (8x-2)\,y(x) = 0$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

  - Convert $x^m \cdot y(x)$ to series expansion for $m = 0..1$

    $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

  - Shift index using $k->k-m$

    $x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

  - Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m = 1..2$

    $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$

  - Shift index using $k->k+1-m$

    $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$

  - Convert $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

    $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\,x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(1+2r)(-2+r)\,x^r + \left(\sum_{k=1}^{\infty} \left(a_k(2k+2r+1)(k+r-2) - 2a_{k-1}(k-5+r)\right) x^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$(1+2r)(-2+r)=0$

- Values of r that satisfy the indicial equation

$r\in\left\{2,-\frac{1}{2}\right\}$

- Each term in the series must be 0, giving the recursion relation

$2\left(k+r+\frac{1}{2}\right)(k+r-2)a_k-2a_{k-1}(k-5+r)=0$

- Shift index using $k->k+1$

$2\left(k+\frac{3}{2}+r\right)(k+r-1)a_{k+1}-2a_k(k+r-4)=0$

- Recursion relation that defines series solution to ODE

$a_{k+1}=\frac{2a_k(k+r-4)}{(2k+3+2r)(k+r-1)}$

- Recursion relation for $r=2$; series terminates at $k=2$

$a_{k+1}=\frac{2a_k(k-2)}{(2k+7)(k+1)}$

- Apply recursion relation for $k=0$

$a_1=-\frac{4a_0}{7}$

- Apply recursion relation for $k=1$

$a_2=-\frac{a_1}{9}$

- Express in terms of a_0

$a_2=\frac{4a_0}{63}$

- Terminating series solution of the ODE for $r=2$. Use reduction of order to find the second linea

$y(x)=a_0\cdot\left(1-\frac{4}{7}x+\frac{4}{63}x^2\right)$

- Recursion relation for $r=-\frac{1}{2}$

$a_{k+1}=\frac{2a_k\left(k-\frac{9}{2}\right)}{(2k+2)\left(k-\frac{3}{2}\right)}$

- Solution for $r=-\frac{1}{2}$

$\left[y(x)=\sum_{k=0}^{\infty}a_k x^{k-\frac{1}{2}},a_{k+1}=\frac{2a_k\left(k-\frac{9}{2}\right)}{(2k+2)\left(k-\frac{3}{2}\right)}\right]$

- Combine solutions and rename parameters

$\left[y(x)=a_0\cdot\left(1-\frac{4}{7}x+\frac{4}{63}x^2\right)+\left(\sum_{k=0}^{\infty}b_k x^{k-\frac{1}{2}}\right),b_{k+1}=\frac{2b_k\left(k-\frac{9}{2}\right)}{(2k+2)\left(k-\frac{3}{2}\right)}\right]$

Solve

$$4x^2y'' - 4x^2y' + (1+2x)\,y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.221 (sec)

Writing the ode as

$$4x^2y'' - 4x^2y' + (1+2x)\,y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4x^2 \\ B &= -4x^2 \\ C &= 1+2x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 - 2x - 1}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2 - 2x - 1 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2 - 2x - 1}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.443: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} - \frac{1}{2x} - \frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} - \frac{1}{2x} - \frac{1}{2x^2} - \frac{1}{2x^3} - \frac{3}{4x^4} - \frac{5}{4x^5} - \frac{9}{4x^6} - \frac{17}{4x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 - 2x - 1}{4x^2} \\ &= Q + \frac{R}{4x^2} \\ &= \left(\frac{1}{4}\right) + \left(\frac{-2x - 1}{4x^2}\right) \\ &= \frac{1}{4} + \frac{-2x - 1}{4x^2} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is -2. Dividing this by leading coefficient in t which is 4 gives $-\frac{1}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{1}{2}\right) - (0) \\ &= -\frac{1}{2} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &&= -\frac{1}{2} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &&= \frac{1}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2 - 2x - 1}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	$-\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^+\right) \\ &= \frac{1}{2} - \left(\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{1}{2x} + (-)\left(\frac{1}{2}\right) \\ &= \frac{1}{2x} - \frac{1}{2} \\ &= -\frac{x-1}{2x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(\frac{1}{2x} - \frac{1}{2}\right)(0) + \left(\left(-\frac{1}{2x^2}\right) + \left(\frac{1}{2x} - \frac{1}{2}\right)^2 - \left(\frac{x^2-2x-1}{4x^2}\right) \right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= e^{\int \left(\frac{1}{2x} - \frac{1}{2}\right) dx} \\ &= \sqrt{x}\, e^{-\frac{x}{2}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-4x^2}{4x^2}\,dx} \\ &= z_1 e^{\frac{x}{2}} \\ &= z_1\left(\mathrm{e}^{\frac{x}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \sqrt{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-4x^2}{4x^2}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{x}}{(y_1)^2}\,dx \\ &= y_1(-\operatorname{Ei}_1(-x)) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\sqrt{x}\right) + c_2\left(\sqrt{x}(-\operatorname{Ei}_1(-x))\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$4x^2\left(\frac{d^2}{dx^2}y(x)\right) - 4x^2\left(\frac{d}{dx}y(x)\right) + (2x+1)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{(2x+1)y(x)}{4x^2} + \frac{d}{dx}y(x)$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x) - \frac{d}{dx}y(x) + \frac{(2x+1)y(x)}{4x^2} = 0$

☐ Check to see if $x_0 = 0$ is a regular singular point

  - Define functions

    $\left[P_2(x) = -1, P_3(x) = \frac{2x+1}{4x^2}\right]$

  - $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left.(x \cdot P_2(x))\right|_{x=0} = 0$

  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$

$(x^2 \cdot P_3(x))\bigg|_{x=0} = \frac{1}{4}$

- $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $4x^2\left(\frac{d^2}{dx^2}y(x)\right) - 4x^2\left(\frac{d}{dx}y(x)\right) + (2x+1)\,y(x) = 0$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

- ☐ Rewrite ODE with series expansions
  - Convert $x^m \cdot y(x)$ to series expansion for $m = 0..1$

    $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

  - Shift index using $k- >k-m$

    $x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

  - Convert $x^2 \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion

    $x^2 \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r+1}$

  - Shift index using $k- >k-1$

    $x^2 \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=1}^{\infty} a_{k-1}(k-1+r)\,x^{k+r}$

  - Convert $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

    $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k-1+r)\,x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(-1+2r)^2\,x^r + \left(\sum_{k=1}^{\infty} \left(a_k(2k+2r-1)^2 - 2a_{k-1}(2k-3+2r)\right)x^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-1+2r)^2 = 0$

- Values of r that satisfy the indicial equation

  $r = \frac{1}{2}$

- Each term in the series must be 0, giving the recursion relation

  $a_k(2k+2r-1)^2 + (-4k-4r+6)\,a_{k-1} = 0$

- Shift index using $k- >k+1$

  $a_{k+1}(2k+1+2r)^2 + a_k(-4k-4r+2) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+1} = \frac{2a_k(2k+2r-1)}{(2k+1+2r)^2}$

- Recursion relation for $r = \frac{1}{2}$

  $a_{k+1} = \frac{4a_k k}{(2k+2)^2}$

- Solution for $r = \frac{1}{2}$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}, a_{k+1} = \frac{4a_k k}{(2k+2)^2}\right]$

2.1.233 Problem 236

Internal problem ID [9405]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 236
Date solved : `Monday, January 27, 2025 at 06:02:28 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' + x(3-2x)\,y' + (1-2x)\,y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.248 (sec)

Writing the ode as

$$x^2y'' + \left(-2x^2+3x\right)y' + (1-2x)\,y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -2x^2+3x \\ C &= 1-2x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{4x^2-4x-1}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 4x^2-4x-1 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{4x^2-4x-1}{4x^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.445: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s)\\ &= 2 - 2\\ &= 0\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = 1 - \frac{1}{x} - \frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2}\\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}\end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i\\ &= \sum_{i=0}^{0} a_i x^i \qquad (8)\end{aligned}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx 1 - \frac{1}{2x} - \frac{1}{4x^2} - \frac{1}{8x^3} - \frac{3}{32x^4} - \frac{5}{64x^5} - \frac{9}{128x^6} - \frac{17}{256x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = 1$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= 1 \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = 1$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{4x^2 - 4x - 1}{4x^2} \\ &= Q + \frac{R}{4x^2} \\ &= (1) + \left(\frac{-4x - 1}{4x^2}\right) \\ &= 1 + \frac{-4x - 1}{4x^2} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is -4. Dividing this by leading coefficient in t which is 4 gives -1. Now b can be found.

$$\begin{aligned} b &= (-1) - (0) \\ &= -1 \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= 1 \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-1}{1} - 0\right) &= -\frac{1}{2} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-1}{1} - 0\right) &= \frac{1}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{4x^2 - 4x - 1}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	1	$-\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^- - (\alpha_{c_1}^+) \\ &= \frac{1}{2} - \left(\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{1}{2x} + (-)(1) \\ &= \frac{1}{2x} - 1 \\ &= \frac{1}{2x} - 1 \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(\frac{1}{2x} - 1\right)(0) + \left(\left(-\frac{1}{2x^2}\right) + \left(\frac{1}{2x} - 1\right)^2 - \left(\frac{4x^2 - 4x - 1}{4x^2}\right) \right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= e^{\int \left(\frac{1}{2x} - 1\right) dx} \\ &= \sqrt{x}\, e^{-x} \end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-2x^2+3x}{x^2}\,dx} \\
&= z_1 e^{x-\frac{3\ln(x)}{2}} \\
&= z_1\left(\frac{e^x}{x^{3/2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{1}{x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-2x^2+3x}{x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{2x-3\ln(x)}}{(y_1)^2}\,dx \\
&= y_1(-\operatorname{Ei}_1(-2x))
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{1}{x}\right) + c_2\left(\frac{1}{x}(-\operatorname{Ei}_1(-2x))\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve
$x^2\left(\frac{d^2}{dx^2}y(x)\right) + x(3-2x)\left(\frac{d}{dx}y(x)\right) + (-2x+1)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2
  $\frac{d^2}{dx^2}y(x)$
- Isolate 2nd derivative
  $\frac{d^2}{dx^2}y(x) = \frac{(2x-1)y(x)}{x^2} + \frac{(2x-3)\left(\frac{d}{dx}y(x)\right)}{x}$
- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin
  $\frac{d^2}{dx^2}y(x) - \frac{(2x-3)\left(\frac{d}{dx}y(x)\right)}{x} - \frac{(2x-1)y(x)}{x^2} = 0$

☐ Check to see if $x_0 = 0$ is a regular singular point
  - Define functions
    $\left[P_2(x) = -\frac{2x-3}{x}, P_3(x) = -\frac{2x-1}{x^2}\right]$
  - $x \cdot P_2(x)$ is analytic at $x = 0$

$\left(x \cdot P_2(x)\right)\Big|_{x=0} = 3$

- $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $\left(x^2 \cdot P_3(x)\right)\Big|_{x=0} = 1$

- $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $x^2\left(\frac{d^2}{dx^2}y(x)\right) - (2x-3)\,x\left(\frac{d}{dx}y(x)\right) + (-2x+1)\,y(x) = 0$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $x^m \cdot y(x)$ to series expansion for $m = 0..1$

  $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- Shift index using $k- >k-m$

  $x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m = 1..2$

  $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$

- Shift index using $k- >k+1-m$

  $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$

- Convert $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

  $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(1+r)^2\,x^r + \left(\sum_{k=1}^{\infty} \left(a_k(k+r+1)^2 - 2a_{k-1}(k+r)\right) x^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(1+r)^2 = 0$

- Values of r that satisfy the indicial equation

  $r = -1$

- Each term in the series must be 0, giving the recursion relation

  $a_k(k+r+1)^2 - 2a_{k-1}(k+r) = 0$

- Shift index using $k- >k+1$

  $a_{k+1}(k+2+r)^2 - 2a_k(k+r+1) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+1} = \frac{2a_k(k+r+1)}{(k+2+r)^2}$

- Recursion relation for $r = -1$

  $a_{k+1} = \frac{2a_k k}{(k+1)^2}$

- Solution for $r = -1$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k-1}, a_{k+1} = \frac{2a_k k}{(k+1)^2}\right]$

2.1.234 Problem 237

Internal problem ID [9406]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 237
Date solved : `Monday, January 27, 2025 at 06:02:28 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' - x(3+x)\,y' + (4-x)\,y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.280 (sec)

Writing the ode as

$$x^2y'' + \left(-x^2-3x\right)y' + (4-x)\,y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -x^2-3x \\ C &= 4-x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2+10x-1}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2+10x-1 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2+10x-1}{4x^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.447: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} + \frac{5}{2x} - \frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} + \frac{5}{2x} - \frac{13}{2x^2} + \frac{65}{2x^3} - \frac{819}{4x^4} + \frac{5785}{4x^5} - \frac{43797}{4x^6} + \frac{347425}{4x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 + 10x - 1}{4x^2} \\ &= Q + \frac{R}{4x^2} \\ &= \left(\frac{1}{4}\right) + \left(\frac{10x - 1}{4x^2}\right) \\ &= \frac{1}{4} + \frac{10x - 1}{4x^2} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is 10. Dividing this by leading coefficient in t which is 4 gives $\frac{5}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(\frac{5}{2}\right) - (0) \\ &= \frac{5}{2} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{\frac{5}{2}}{\frac{1}{2}} - 0\right) &= \frac{5}{2} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{\frac{5}{2}}{\frac{1}{2}} - 0\right) &= -\frac{5}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2 + 10x - 1}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	$\frac{5}{2}$	$-\frac{5}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{5}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^+ - (\alpha_{c_1}^+) \\ &= \frac{5}{2} - \left(\frac{1}{2}\right) \\ &= 2 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1} \right) + (+)[\sqrt{r}]_\infty \\ &= \frac{1}{2x} + \left(\frac{1}{2}\right) \\ &= \frac{1}{2x} + \frac{1}{2} \\ &= \frac{1+x}{2x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 2$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = x^2 + a_1 x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{gathered} (2) + 2\left(\frac{1}{2x} + \frac{1}{2}\right)(2x + a_1) + \left(\left(-\frac{1}{2x^2}\right) + \left(\frac{1}{2x} + \frac{1}{2}\right)^2 - \left(\frac{x^2 + 10x - 1}{4x^2}\right)\right) = 0 \\ \frac{(-a_1 + 4)\, x - 2a_0 + a_1}{x} = 0 \end{gathered}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 2, a_1 = 4\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^2 + 4x + 2$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= \left(x^2+4x+2\right) e^{\int \left(\frac{1}{2x}+\frac{1}{2}\right)dx} \\ &= \left(x^2+4x+2\right) e^{\frac{x}{2}+\frac{\ln(x)}{2}} \\ &= \left(x^2+4x+2\right) \sqrt{x}\, e^{\frac{x}{2}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-x^2-3x}{x^2} \, dx} \\ &= z_1 e^{\frac{x}{2}+\frac{3\ln(x)}{2}} \\ &= z_1 \left(x^{3/2} e^{\frac{x}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = x^2 e^x \left(x^2+4x+2\right)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-x^2-3x}{x^2} \, dx}}{(y_1)^2} \, dx \\ &= y_1 \int \frac{e^{x+3\ln(x)}}{(y_1)^2} \, dx \\ &= y_1 \left(-\frac{e^{-x}(-x-3)}{4\left(x^2+4x+2\right)} - \frac{\mathrm{Ei}_1(x)}{4}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(x^2 e^x \left(x^2+4x+2\right)\right) + c_2 \left(x^2 e^x \left(x^2+4x+2\right) \left(-\frac{e^{-x}(-x-3)}{4\left(x^2+4x+2\right)} - \frac{\mathrm{Ei}_1(x)}{4}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2 \left(\frac{d^2}{dx^2}y(x)\right) - x(x+3)\left(\frac{d}{dx}y(x)\right) + (4-x)\, y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = \frac{(-4+x)y(x)}{x^2} + \frac{(x+3)\left(\frac{d}{dx}y(x)\right)}{x}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

$\frac{d^2}{dx^2}y(x) - \frac{(x+3)\left(\frac{d}{dx}y(x)\right)}{x} - \frac{(-4+x)y(x)}{x^2} = 0$

- ☐ Check to see if $x_0 = 0$ is a regular singular point
  - ◦ Define functions

    $\left[P_2(x) = -\frac{x+3}{x}, P_3(x) = -\frac{-4+x}{x^2}\right]$
  - ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left.(x \cdot P_2(x))\right|_{x=0} = -3$
  - ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $\left.(x^2 \cdot P_3(x))\right|_{x=0} = 4$
  - ◦ $x = 0$is a regular singular point

    Check to see if $x_0 = 0$ is a regular singular point

    $x_0 = 0$
- Multiply by denominators

  $x^2\left(\frac{d^2}{dx^2}y(x)\right) - x(x+3)\left(\frac{d}{dx}y(x)\right) + (4-x)\,y(x) = 0$
- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$
- ☐ Rewrite ODE with series expansions
  - ◦ Convert $x^m \cdot y(x)$ to series expansion for $m = 0..1$

    $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$
  - ◦ Shift index using $k- >k-m$

    $x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$
  - ◦ Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m = 1..2$

    $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$
  - ◦ Shift index using $k- >k+1-m$

    $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$
  - ◦ Convert $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

    $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r}$

    Rewrite ODE with series expansions

    $a_0(-2+r)^2\,x^r + \left(\sum_{k=1}^{\infty} \left(a_k(k+r-2)^2 - a_{k-1}(k+r)\right) x^{k+r}\right) = 0$
- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-2+r)^2 = 0$
- Values of r that satisfy the indicial equation

  $r = 2$
- Each term in the series must be 0, giving the recursion relation

  $a_k(k+r-2)^2 - a_{k-1}(k+r) = 0$
- Shift index using $k- >k+1$

  $a_{k+1}(k+r-1)^2 - a_k(k+r+1) = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+1} = \frac{a_k(k+r+1)}{(k+r-1)^2}$
- Recursion relation for $r = 2$

$a_{k+1} = \frac{a_k(k+3)}{(k+1)^2}$

- Solution for $r = 2$

$$\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+2}, a_{k+1} = \frac{a_k(k+3)}{(k+1)^2}\right]$$

2.1.235 Problem 238

Internal problem ID [9407]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 238
Date solved : `Monday, January 27, 2025 at 06:02:29 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' + x(3-x)\,y' + y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.276 (sec)

Writing the ode as

$$x^2y'' + \left(-x^2+3x\right)y' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -x^2+3x \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2-6x-1}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2-6x-1 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2-6x-1}{4x^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.449: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} - \frac{3}{2x} - \frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} - \frac{3}{2x} - \frac{5}{2x^2} - \frac{15}{2x^3} - \frac{115}{4x^4} - \frac{495}{4x^5} - \frac{2285}{4x^6} - \frac{11055}{4x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{2}\end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned}r &= \frac{s}{t} \\ &= \frac{x^2 - 6x - 1}{4x^2} \\ &= Q + \frac{R}{4x^2} \\ &= \left(\frac{1}{4}\right) + \left(\frac{-6x - 1}{4x^2}\right) \\ &= \frac{1}{4} + \frac{-6x - 1}{4x^2}\end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is -6. Dividing this by leading coefficient in t which is 4 gives $-\frac{3}{2}$. Now b can be found.

$$\begin{aligned}b &= \left(-\frac{3}{2}\right) - (0) \\ &= -\frac{3}{2}\end{aligned}$$

Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= \frac{1}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{3}{2}}{\frac{1}{2}} - 0\right) &&= -\frac{3}{2} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{3}{2}}{\frac{1}{2}} - 0\right) &&= \frac{3}{2}\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2 - 6x - 1}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	$-\frac{3}{2}$	$\frac{3}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{3}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^+\right) \\ &= \frac{3}{2} - \left(\frac{1}{2}\right) \\ &= 1 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{1}{2x} + (-)\left(\frac{1}{2}\right) \\ &= \frac{1}{2x} - \frac{1}{2} \\ &= -\frac{-1+x}{2x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{gathered} (0) + 2\left(\frac{1}{2x} - \frac{1}{2}\right)(1) + \left(\left(-\frac{1}{2x^2}\right) + \left(\frac{1}{2x} - \frac{1}{2}\right)^2 - \left(\frac{x^2-6x-1}{4x^2}\right)\right) = 0 \\ \frac{1+a_0}{x} = 0 \end{gathered}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = -1\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = -1 + x$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= (-1+x)\, e^{\int \left(\frac{1}{2x}-\frac{1}{2}\right)dx} \\
&= (-1+x)\, e^{-\frac{x}{2}+\frac{\ln(x)}{2}} \\
&= (-1+x)\sqrt{x}\, e^{-\frac{x}{2}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-x^2+3x}{x^2}\, dx} \\
&= z_1 e^{\frac{x}{2}-\frac{3\ln(x)}{2}} \\
&= z_1 \left(\frac{e^{\frac{x}{2}}}{x^{3/2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{-1+x}{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-x^2+3x}{x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{x-3\ln(x)}}{(y_1)^2}\, dx \\
&= y_1 \left(-\frac{e^x}{-1+x} - \mathrm{Ei}_1(-x)\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{-1+x}{x}\right) + c_2\left(\frac{-1+x}{x}\left(-\frac{e^x}{-1+x} - \mathrm{Ei}_1(-x)\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve
$x^2\left(\frac{d^2}{dx^2}y(x)\right)+x(-x+3)\left(\frac{d}{dx}y(x)\right)+y(x)=0$

- Highest derivative means the order of the ODE is 2
$\frac{d^2}{dx^2}y(x)$
- Isolate 2nd derivative
$\frac{d^2}{dx^2}y(x)=-\frac{y(x)}{x^2}+\frac{(x-3)\left(\frac{d}{dx}y(x)\right)}{x}$
- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea
$\frac{d^2}{dx^2}y(x)-\frac{(x-3)\left(\frac{d}{dx}y(x)\right)}{x}+\frac{y(x)}{x^2}=0$
- ☐ Check to see if $x_0=0$ is a regular singular point
  - Define functions
  $\left[P_2(x)=-\frac{x-3}{x},P_3(x)=\frac{1}{x^2}\right]$
  - $x\cdot P_2(x)$ is analytic at $x=0$
  $\left.(x\cdot P_2(x))\right|_{x=0}=3$
  - $x^2\cdot P_3(x)$ is analytic at $x=0$
  $\left.(x^2\cdot P_3(x))\right|_{x=0}=1$
  - $x=0$is a regular singular point
  Check to see if $x_0=0$ is a regular singular point
  $x_0=0$
- Multiply by denominators
$x^2\left(\frac{d^2}{dx^2}y(x)\right)-x(x-3)\left(\frac{d}{dx}y(x)\right)+y(x)=0$
- Assume series solution for $y(x)$
$y(x)=\sum_{k=0}^{\infty}a_kx^{k+r}$
- ☐ Rewrite ODE with series expansions
  - Convert $x^m\cdot\left(\frac{d}{dx}y(x)\right)$ to series expansion for $m=1..2$
  $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,x^{k+r-1+m}$
  - Shift index using $k->k+1-m$
  $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,x^{k+r}$
  - Convert $x^2\cdot\left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion
  $x^2\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,x^{k+r}$
  Rewrite ODE with series expansions
  $a_0(1+r)^2\,x^r+\left(\sum_{k=1}^{\infty}\left(a_k(k+r+1)^2-a_{k-1}(k+r-1)\right)x^{k+r}\right)=0$
- $a_0$cannot be 0 by assumption, giving the indicial equation
$(1+r)^2=0$
- Values of r that satisfy the indicial equation
$r=-1$
- Each term in the series must be 0, giving the recursion relation
$a_k(k+r+1)^2-a_{k-1}(k+r-1)=0$
- Shift index using $k->k+1$

$a_{k+1}(k+2+r)^2 - a_k(k+r) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+1} = \frac{a_k(k+r)}{(k+2+r)^2}$

- Recursion relation for $r = -1$; series terminates at $k = 1$

  $a_{k+1} = \frac{a_k(k-1)}{(k+1)^2}$

- Apply recursion relation for $k = 0$

  $a_1 = -a_0$

- Terminating series solution of the ODE for $r = -1$. Use reduction of order to find the second

  $y(x) = a_0 \cdot (1 - x)$

2.1.236 Problem 239

Internal problem ID [9408]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 239
Date solved : `Monday, January 27, 2025 at 06:02:30 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' - \left(2\sqrt{5}-1\right)xy' + \left(\frac{19}{4} - 3x^2\right)y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.146 (sec)

Writing the ode as

$$x^2y'' + \left(-2x\sqrt{5}+x\right)y' + \left(\frac{19}{4} - 3x^2\right)y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -2x\sqrt{5}+x \\ C &= \frac{19}{4} - 3x^2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{3}{1} \tag{6}$$

Comparing the above to (5) shows that

$$s = 3$$
$$t = 1$$

Therefore eq. (4) becomes

$$z''(x) = 3z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.451: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s)\\ &= 0 - 0\\ &= 0\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 3$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\sqrt{3}\, x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx}\\ &= z_1 e^{-\int \frac{1}{2}\frac{-2x\sqrt{5}+x}{x^2}\, dx}\\ &= z_1 e^{\ln(x)\sqrt{5}-\frac{\ln(x)}{2}}\\ &= z_1\left(x^{\sqrt{5}-\frac{1}{2}}\right)\end{aligned}$$

Which simplifies to

$$y_1 = x^{\sqrt{5}-\frac{1}{2}}\mathrm{e}^{-\sqrt{3}\, x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-2x\sqrt{5}+x}{x^2}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{\ln(x)\left(2\sqrt{5}-1\right)}}{(y_1)^2}\, dx \\ &= y_1 \left(\frac{\mathrm{e}^{\ln(x)\left(2\sqrt{5}-1\right)} x^{1-2\sqrt{5}} \mathrm{e}^{2\sqrt{3}\,x} \sqrt{3}}{6}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(x^{\sqrt{5}-\frac{1}{2}} \mathrm{e}^{-\sqrt{3}\,x}\right) + c_2 \left(x^{\sqrt{5}-\frac{1}{2}} \mathrm{e}^{-\sqrt{3}\,x} \left(\frac{\mathrm{e}^{\ln(x)\left(2\sqrt{5}-1\right)} x^{1-2\sqrt{5}} \mathrm{e}^{2\sqrt{3}\,x} \sqrt{3}}{6}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2 \left(\frac{d^2}{dx^2} y(x)\right) - \left(-1 + 2\sqrt{5}\right) x \left(\frac{d}{dx} y(x)\right) + \left(\frac{19}{4} - 3x^2\right) y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2} y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2} y(x) = \frac{(12x^2-19) y(x)}{4x^2} + \frac{\left(-1+2\sqrt{5}\right)\left(\frac{d}{dx} y(x)\right)}{x}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2} y(x) - \frac{\left(-1+2\sqrt{5}\right)\left(\frac{d}{dx} y(x)\right)}{x} - \frac{(12x^2-19) y(x)}{4x^2} = 0$

- ☐ Check to see if $x_0 = 0$ is a regular singular point
  - Define functions

    $\left[P_2(x) = -\frac{-1+2\sqrt{5}}{x}, P_3(x) = -\frac{12x^2-19}{4x^2}\right]$

  - $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left.(x \cdot P_2(x))\right|_{x=0} = 1 - 2\sqrt{5}$

  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $\left.(x^2 \cdot P_3(x))\right|_{x=0} = \frac{19}{4}$

  - $x = 0$is a regular singular point

    Check to see if $x_0 = 0$ is a regular singular point

    $x_0 = 0$

- Multiply by denominators

  $4x^2 \left(\frac{d^2}{dx^2} y(x)\right) - 4\left(-1 + 2\sqrt{5}\right) x \left(\frac{d}{dx} y(x)\right) + \left(-12x^2 + 19\right) y(x) = 0$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

- □ Rewrite ODE with series expansions
  - Convert $x^m \cdot y(x)$ to series expansion for $m = 0..2$

    $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$
  - Shift index using $k- > k - m$

    $x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$
  - Convert $x \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion

    $x \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r}$
  - Convert $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

    $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r}$

  Rewrite ODE with series expansions

  $\left(1+2\sqrt{5}-2r\right)\left(-1+2\sqrt{5}-2r\right) a_0 x^r + \left(-1+2\sqrt{5}-2r\right)\left(-3+2\sqrt{5}-2r\right) a_1 x^{1+r} + \left(\sum_{k=2}^{\infty} \left(\left(-\right.\right.\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $\left(1+2\sqrt{5}-2r\right)\left(-1+2\sqrt{5}-2r\right) = 0$
- Values of r that satisfy the indicial equation

  $r \in \left\{-\frac{1}{2}+\sqrt{5}, \frac{1}{2}+\sqrt{5}\right\}$
- Each term must be 0

  $\left(-1+2\sqrt{5}-2r\right)\left(-3+2\sqrt{5}-2r\right) a_1 = 0$
- Solve for the dependent coefficient(s)

  $a_1 = 0$
- Each term in the series must be 0, giving the recursion relation

  $-8a_k(k+r)\sqrt{5} + \left(4k^2+8kr+4r^2+19\right) a_k - 12a_{k-2} = 0$
- Shift index using $k- > k + 2$

  $-8a_{k+2}(k+2+r)\sqrt{5} + \left(4(k+2)^2 + 8(k+2)\,r + 4r^2 + 19\right) a_{k+2} - 12a_k = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{12a_k}{-35+8k\sqrt{5}+8\sqrt{5}\,r-4k^2-8kr-4r^2+16\sqrt{5}-16k-16r}$
- Recursion relation for $r = -\frac{1}{2}+\sqrt{5}$

  $a_{k+2} = -\frac{12a_k}{-27+8k\sqrt{5}+8\sqrt{5}\left(-\frac{1}{2}+\sqrt{5}\right)-4k^2-8k\left(-\frac{1}{2}+\sqrt{5}\right)-4\left(-\frac{1}{2}+\sqrt{5}\right)^2-16k}$
- Solution for $r = -\frac{1}{2}+\sqrt{5}$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k-\frac{1}{2}+\sqrt{5}}, a_{k+2} = -\frac{12a_k}{-27+8k\sqrt{5}+8\sqrt{5}\left(-\frac{1}{2}+\sqrt{5}\right)-4k^2-8k\left(-\frac{1}{2}+\sqrt{5}\right)-4\left(-\frac{1}{2}+\sqrt{5}\right)^2-16k}, a_1 = 0\right]$
- Recursion relation for $r = \frac{1}{2}+\sqrt{5}$

  $a_{k+2} = -\frac{12a_k}{-43+8k\sqrt{5}+8\sqrt{5}\left(\frac{1}{2}+\sqrt{5}\right)-4k^2-8k\left(\frac{1}{2}+\sqrt{5}\right)-4\left(\frac{1}{2}+\sqrt{5}\right)^2-16k}$
- Solution for $r = \frac{1}{2}+\sqrt{5}$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}+\sqrt{5}}, a_{k+2} = -\frac{12a_k}{-43+8k\sqrt{5}+8\sqrt{5}\left(\frac{1}{2}+\sqrt{5}\right)-4k^2-8k\left(\frac{1}{2}+\sqrt{5}\right)-4\left(\frac{1}{2}+\sqrt{5}\right)^2-16k}, a_1 = 0\right]$
- Combine solutions and rename parameters

$$\left[y(x)=\left(\sum_{k=0}^{\infty} a_k x^{k-\frac{1}{2}+\sqrt{5}}\right)+\left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{2}+\sqrt{5}}\right), a_{k+2}=-\frac{12a_k}{-27+8k\sqrt{5}+8\sqrt{5}\left(-\frac{1}{2}+\sqrt{5}\right)-4k^2-8k\left(-\frac{1}{2}+\sqrt{5}\right)-4\left(-\right.}\right.$$

2.1.237 Problem 240

Internal problem ID [9409]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 240
Date solved : `Monday, January 27, 2025 at 06:02:30 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' + x(x-3)\,y' + (4-x)\,y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.232 (sec)

Writing the ode as

$$x^2y'' + \left(x^2-3x\right)y' + (4-x)\,y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= x^2-3x \\ C &= 4-x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2-2x-1}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2-2x-1 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2-2x-1}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.453: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} - \frac{1}{2x} - \frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} - \frac{1}{2x} - \frac{1}{2x^2} - \frac{1}{2x^3} - \frac{3}{4x^4} - \frac{5}{4x^5} - \frac{9}{4x^6} - \frac{17}{4x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 - 2x - 1}{4x^2} \\ &= Q + \frac{R}{4x^2} \\ &= \left(\frac{1}{4}\right) + \left(\frac{-2x - 1}{4x^2}\right) \\ &= \frac{1}{4} + \frac{-2x - 1}{4x^2} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is -2. Dividing this by leading coefficient in t which is 4 gives $-\frac{1}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{1}{2}\right) - (0) \\ &= -\frac{1}{2} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &= -\frac{1}{2} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &= \frac{1}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2 - 2x - 1}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	$-\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^+\right) \\ &= \frac{1}{2} - \left(\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{1}{2x} + (-)\left(\frac{1}{2}\right) \\ &= \frac{1}{2x} - \frac{1}{2} \\ &= -\frac{x-1}{2x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{gathered} (0) + 2\left(\frac{1}{2x} - \frac{1}{2}\right)(0) + \left(\left(-\frac{1}{2x^2}\right) + \left(\frac{1}{2x} - \frac{1}{2}\right)^2 - \left(\frac{x^2-2x-1}{4x^2}\right)\right) = 0 \\ 0 = 0 \end{gathered}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega\, dx} \\ &= e^{\int \left(\frac{1}{2x} - \frac{1}{2}\right) dx} \\ &= \sqrt{x}\, e^{-\frac{x}{2}} \end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{x^2-3x}{x^2}\,dx} \\
&= z_1 e^{-\frac{x}{2}+\frac{3\ln(x)}{2}} \\
&= z_1\left(x^{3/2}\mathrm{e}^{-\frac{x}{2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = x^2\mathrm{e}^{-x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x^2-3x}{x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-x+3\ln(x)}}{(y_1)^2}\,dx \\
&= y_1(-\operatorname{Ei}_1(-x))
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1y_1 + c_2y_2 \\
&= c_1\left(x^2\mathrm{e}^{-x}\right) + c_2\left(x^2\mathrm{e}^{-x}(-\operatorname{Ei}_1(-x))\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2\left(\frac{d^2}{dx^2}y(x)\right) + x(x-3)\left(\frac{d}{dx}y(x)\right) + (4-x)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = \frac{(-4+x)y(x)}{x^2} - \frac{(x-3)\left(\frac{d}{dx}y(x)\right)}{x}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x) + \frac{(x-3)\left(\frac{d}{dx}y(x)\right)}{x} - \frac{(-4+x)y(x)}{x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  - Define functions

    $\left[P_2(x) = \frac{x-3}{x}, P_3(x) = -\frac{-4+x}{x^2}\right]$

  - $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left.(x \cdot P_2(x))\right|_{x=0} = -3$

  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$

$$\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = 4$$

- $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $x^2\left(\frac{d^2}{dx^2}y(x)\right) + x(x-3)\left(\frac{d}{dx}y(x)\right) + (4-x)\,y(x) = 0$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

- ☐ Rewrite ODE with series expansions

  - Convert $x^m \cdot y(x)$ to series expansion for $m = 0..1$

    $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

  - Shift index using $k- >k-m$

    $x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

  - Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m = 1..2$

    $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$

  - Shift index using $k- >k+1-m$

    $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$

  - Convert $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

    $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(-2+r)^2\,x^r + \left(\sum_{k=1}^{\infty} \left(a_k(k+r-2)^2 + a_{k-1}(k+r-2)\right) x^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-2+r)^2 = 0$

- Values of r that satisfy the indicial equation

  $r = 2$

- Each term in the series must be 0, giving the recursion relation

  $(k+r-2)\,(a_k(k+r-2) + a_{k-1}) = 0$

- Shift index using $k- >k+1$

  $(k+r-1)\,(a_{k+1}(k+r-1) + a_k) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+1} = -\frac{a_k}{k+r-1}$

- Recursion relation for $r = 2$

  $a_{k+1} = -\frac{a_k}{k+1}$

- Solution for $r = 2$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+2}, a_{k+1} = -\frac{a_k}{k+1}\right]$

Solve

$$x^2y'' + x^2y' - (2 + x)\, y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.208 (sec)

Writing the ode as

$$x^2y'' + x^2y' + (-x - 2)\, y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= x^2 \\ C &= -x - 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 + 4x + 8}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2 + 4x + 8 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2 + 4x + 8}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.455: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} + \frac{2}{x^2} + \frac{1}{x}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1 \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} + \frac{1}{x} + \frac{1}{x^2} - \frac{2}{x^3} + \frac{3}{x^4} - \frac{2}{x^5} - \frac{6}{x^6} + \frac{28}{x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 + 4x + 8}{4x^2} \\ &= Q + \frac{R}{4x^2} \\ &= \left(\frac{1}{4}\right) + \left(\frac{4x + 8}{4x^2}\right) \\ &= \frac{1}{4} + \frac{4x + 8}{4x^2} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is 4. Dividing this by leading coefficient in t which is 4 gives 1. Now b can be found.

$$\begin{aligned} b &= (1) - (0) \\ &= 1 \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{2} \\ \alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{1}{\frac{1}{2}} - 0\right) &&= 1 \\ \alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{1}{\frac{1}{2}} - 0\right) &&= -1 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2 + 4x + 8}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	2	-1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	1	-1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -1$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\ &= -1 - (-1) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= -\frac{1}{x} + (-)\left(\frac{1}{2}\right) \\ &= -\frac{1}{x} - \frac{1}{2} \\ &= -\frac{2+x}{2x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(-\frac{1}{x} - \frac{1}{2}\right)(0) + \left(\left(\frac{1}{x^2}\right) + \left(-\frac{1}{x} - \frac{1}{2}\right)^2 - \left(\frac{x^2+4x+8}{4x^2}\right) \right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= e^{\int \left(-\frac{1}{x} - \frac{1}{2}\right) dx} \\ &= \frac{e^{-\frac{x}{2}}}{x} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{x^2}{x^2}\,dx} \\ &= z_1 e^{-\frac{x}{2}} \\ &= z_1\left(\mathrm{e}^{-\frac{x}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{\mathrm{e}^{-x}}{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{x^2}{x^2}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{-x}}{(y_1)^2}\,dx \\ &= y_1\left(\left(x^2-2x+2\right)\mathrm{e}^{x}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\frac{\mathrm{e}^{-x}}{x}\right) + c_2\left(\frac{\mathrm{e}^{-x}}{x}\left(\left(x^2-2x+2\right)\mathrm{e}^{x}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2\left(\frac{d^2}{dx^2}y(x)\right) + x^2\left(\frac{d}{dx}y(x)\right) - (x+2)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = \frac{(x+2)y(x)}{x^2} - \frac{d}{dx}y(x)$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x) + \frac{d}{dx}y(x) - \frac{(x+2)y(x)}{x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  - Define functions

    $\left[P_2(x) = 1, P_3(x) = -\frac{x+2}{x^2}\right]$

  - $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left.(x \cdot P_2(x))\right|_{x=0} = 0$

  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$

$$\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = -2$$

- ◦ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $x^2\left(\frac{d^2}{dx^2}y(x)\right) + x^2\left(\frac{d}{dx}y(x)\right) + (-x-2)\,y(x) = 0$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

- □ Rewrite ODE with series expansions

  - ◦ Convert $x^m \cdot y(x)$ to series expansion for $m = 0..1$

    $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

  - ◦ Shift index using $k- >k-m$

    $x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

  - ◦ Convert $x^2 \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion

    $x^2 \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r+1}$

  - ◦ Shift index using $k- >k-1$

    $x^2 \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=1}^{\infty} a_{k-1}(k-1+r)\,x^{k+r}$

  - ◦ Convert $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

    $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k-1+r)\,x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(1+r)\,(-2+r)\,x^r + \left(\sum_{k=1}^{\infty} \left(a_k(k+r+1)\,(k+r-2) + a_{k-1}(k+r-2)\right) x^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(1+r)\,(-2+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{-1, 2\}$

- Each term in the series must be 0, giving the recursion relation

  $(k+r-2)\left(a_k(k+r+1) + a_{k-1}\right) = 0$

- Shift index using $k- >k+1$

  $(k-1+r)\left(a_{k+1}(k+2+r) + a_k\right) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+1} = -\frac{a_k}{k+2+r}$

- Recursion relation for $r = -1$

  $a_{k+1} = -\frac{a_k}{k+1}$

- Solution for $r = -1$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k-1}, a_{k+1} = -\frac{a_k}{k+1}\right]$

- Recursion relation for $r = 2$

  $a_{k+1} = -\frac{a_k}{k+4}$

- Solution for $r = 2$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+2}, a_{k+1} = -\frac{a_k}{k+4}\right]$

- Combine solutions and rename parameters

$$\left[y(x)=\left(\sum_{k=0}^{\infty}a_k x^{k-1}\right)+\left(\sum_{k=0}^{\infty}b_k x^{k+2}\right), a_{k+1}=-\frac{a_k}{k+1}, b_{k+1}=-\frac{b_k}{4+k}\right]$$

2.1.239 Problem 242

Internal problem ID [9411]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 242
Date solved : `Monday, January 27, 2025 at 06:02:31 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' + 2x^2y' + \left(x - \frac{3}{4}\right)y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.208 (sec)

Writing the ode as

$$x^2y'' + 2x^2y' + \left(x - \frac{3}{4}\right)y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= 2x^2 \\ C &= x - \frac{3}{4} \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{4x^2 - 4x + 3}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 4x^2 - 4x + 3 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{4x^2 - 4x + 3}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.457: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = 1 - \frac{1}{x} + \frac{3}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\
&= \sum_{i=0}^{0} a_i x^i
\end{aligned} \tag{8}
$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$
\sqrt{r} \approx 1 - \frac{1}{2x} + \frac{1}{4x^2} + \frac{1}{8x^3} + \frac{1}{32x^4} - \frac{1}{64x^5} - \frac{3}{128x^6} - \frac{3}{256x^7} + \dots \tag{9}
$$

Comparing Eq. (9) with Eq. (8) shows that

$$
a = 1
$$

From Eq. (9) the sum up to $v = 0$ gives

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\
&= 1
\end{aligned} \tag{10}
$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$
\left([\sqrt{r}]_\infty\right)^2 = 1
$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$
r = Q + \frac{R}{t}
$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{4x^2 - 4x + 3}{4x^2} \\
&= Q + \frac{R}{4x^2} \\
&= (1) + \left(\frac{-4x + 3}{4x^2}\right) \\
&= 1 + \frac{-4x + 3}{4x^2}
\end{aligned}
$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is -4. Dividing this by leading coefficient in t which is 4 gives -1. Now b can be found.

$$
\begin{aligned}
b &= (-1) - (0) \\
&= -1
\end{aligned}
$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 1 \\
\alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-1}{1} - 0\right) &= -\frac{1}{2} \\
\alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-1}{1} - 0\right) &= \frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{4x^2 - 4x + 3}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	1	$-\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = -\frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^+ - (\alpha_{c_1}^-) \\ &= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x - c_1} \right) + (+)[\sqrt{r}]_\infty \\ &= -\frac{1}{2x} + (1) \\ &= 1 - \frac{1}{2x} \\ &= 1 - \frac{1}{2x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(1 - \frac{1}{2x}\right)(0) + \left(\left(\frac{1}{2x^2}\right) + \left(1 - \frac{1}{2x}\right)^2 - \left(\frac{4x^2 - 4x + 3}{4x^2}\right)\right) = 0$$

$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \,dx} \\
&= \mathrm{e}^{\int (1-\frac{1}{2x})dx} \\
&= \frac{\mathrm{e}^{x}}{\sqrt{x}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{2x^2}{x^2}\,dx} \\
&= z_1 e^{-x} \\
&= z_1 \left(\mathrm{e}^{-x}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{1}{\sqrt{x}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{2x^2}{x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-2x}}{(y_1)^2}\,dx \\
&= y_1 \left(-\frac{(1+2x)\,\mathrm{e}^{-2x}}{4}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{1}{\sqrt{x}}\right) + c_2 \left(\frac{1}{\sqrt{x}}\left(-\frac{(1+2x)\,\mathrm{e}^{-2x}}{4}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve
$x^2\left(\frac{d^2}{dx^2}y(x)\right) + 2x^2\left(\frac{d}{dx}y(x)\right) + \left(x - \frac{3}{4}\right)y(x) = 0$

2.1.240 Problem 243

Internal problem ID [9412]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 243
Date solved : `Monday, January 27, 2025 at 06:02:32 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2(1+x)\,y''+x^2y'-2y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.184 (sec)

Writing the ode as

$$x^2(1+x)\,y''+x^2y'-2y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2(1+x)\\ B &= x^2\\ C &= -2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{-x^2+8x+8}{4\left(x^2+x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -x^2+8x+8\\ t &= 4\left(x^2+x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{-x^2+8x+8}{4\left(x^2+x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.459: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^2 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{2}{x} + \frac{2}{x^2} - \frac{1}{4\,(1+x)^2} + \frac{2}{1+x}$$

For the pole at $x = -1$ let b be the coefficient of $\frac{1}{(1+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1 \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{-x^2+8x+8}{4\left(x^2+x\right)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{1}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{-x^2+8x+8}{4\left(x^2+x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
-1	2	0	$\frac{1}{2}$	$\frac{1}{2}$
0	2	0	2	-1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^+ + \alpha_{c_2}^-\right) \\
&= \frac{1}{2} - \left(-\frac{1}{2}\right) \\
&= 1
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2} \right) + (-)[\sqrt{r}]_\infty \\
&= \frac{1}{2+2x} - \frac{1}{x} + (-)(0) \\
&= \frac{1}{2+2x} - \frac{1}{x} \\
&= -\frac{x+2}{2x(1+x)}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{2+2x} - \frac{1}{x}\right)(1) + \left(\left(-\frac{1}{2(1+x)^2} + \frac{1}{x^2}\right) + \left(\frac{1}{2+2x} - \frac{1}{x}\right)^2 - \left(\frac{-x^2+8x+8}{4(x^2+x)^2}\right)\right) = 0$$

$$\frac{-2+a_0}{x(1+x)} = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 2\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x + 2$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= (x+2)\, e^{\int \left(\frac{1}{2+2x} - \frac{1}{x}\right) dx} \\
&= (x+2)\, e^{\frac{\ln(1+x)}{2} - \ln(x)} \\
&= \frac{(x+2)\sqrt{1+x}}{x}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{x^2}{x^2(1+x)}\, dx} \\
&= z_1 e^{-\frac{\ln(1+x)}{2}} \\
&= z_1 \left(\frac{1}{\sqrt{1+x}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{x+2}{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x^2}{x^2(1+x)}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-\ln(1+x)}}{(y_1)^2}\, dx \\
&= y_1 \left(\ln(1+x) + \frac{4}{x+2}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\frac{x+2}{x}\right) + c_2\left(\frac{x+2}{x}\left(\ln(1+x) + \frac{4}{x+2}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2(x+1)\left(\frac{d^2}{dx^2}y(x)\right) + x^2\left(\frac{d}{dx}y(x)\right) - 2y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = \frac{2y(x)}{(x+1)x^2} - \frac{\frac{d}{dx}y(x)}{x+1}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x) + \frac{\frac{d}{dx}y(x)}{x+1} - \frac{2y(x)}{(x+1)x^2} = 0$

☐ Check to see if x_0 is a regular singular point

  - Define functions

    $\left[P_2(x) = \frac{1}{x+1}, P_3(x) = -\frac{2}{(x+1)x^2}\right]$

  - $(x+1)\cdot P_2(x)$ is analytic at $x=-1$

    $\left((x+1)\cdot P_2(x)\right)\Big|_{x=-1} = 1$

  - $(x+1)^2\cdot P_3(x)$ is analytic at $x=-1$

    $\left((x+1)^2\cdot P_3(x)\right)\Big|_{x=-1} = 0$

  - $x=-1$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = -1$

- Multiply by denominators

  $x^2(x+1)\left(\frac{d^2}{dx^2}y(x)\right) + x^2\left(\frac{d}{dx}y(x)\right) - 2y(x) = 0$

- Change variables using $x = u-1$ so that the regular singular point is at $u=0$

  $(u^3 - 2u^2 + u)\left(\frac{d^2}{du^2}y(u)\right) + (u^2 - 2u + 1)\left(\frac{d}{du}y(u)\right) - 2y(u) = 0$

- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

☐ Rewrite ODE with series expansions

  - Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..2$

    $u^m\cdot\left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, u^{k+r-1+m}$

  - Shift index using $k->k+1-m$

    $u^m\cdot\left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$

  - Convert $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m = 1..3$

$$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, u^{k+r-2+m}$$

- Shift index using $k- >k+2-m$

$$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\, u^{k+r}$$

Rewrite ODE with series expansions

$$a_0 r^2 u^{-1+r} + \left(a_1(1+r)^2 - 2a_0(r^2+1)\right) u^r + \left(\sum_{k=1}^{\infty} \left(a_{k+1}(k+1+r)^2 - 2a_k(k^2+2kr+r^2+1) + \right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $r^2 = 0$
- Values of r that satisfy the indicial equation
  $r = 0$
- Each term must be 0
  $a_1(1+r)^2 - 2a_0(r^2+1) = 0$
- Each term in the series must be 0, giving the recursion relation
  $a_{k+1}(k+1)^2 - 2a_k(k^2+1) + a_{k-1}(k-1)^2 = 0$
- Shift index using $k- >k+1$
  $a_{k+2}(k+2)^2 - 2a_{k+1}\left((k+1)^2+1\right) + k^2 a_k = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+2} = -\frac{k^2 a_k - 2k^2 a_{k+1} - 4k a_{k+1} - 4a_{k+1}}{(k+2)^2}$
- Recursion relation for $r = 0$
  $a_{k+2} = -\frac{k^2 a_k - 2k^2 a_{k+1} - 4k a_{k+1} - 4a_{k+1}}{(k+2)^2}$
- Solution for $r = 0$
  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+2} = -\frac{k^2 a_k - 2k^2 a_{k+1} - 4k a_{k+1} - 4a_{k+1}}{(k+2)^2}, a_1 - 2a_0 = 0\right]$
- Revert the change of variables $u = x+1$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k (x+1)^k, a_{k+2} = -\frac{k^2 a_k - 2k^2 a_{k+1} - 4k a_{k+1} - 4a_{k+1}}{(k+2)^2}, a_1 - 2a_0 = 0\right]$

2.1.241 Problem 244

Internal problem ID [9413]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 244
Date solved : `Monday, January 27, 2025 at 06:02:33 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' + x(x^2+6)\,y' + 6y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.389 (sec)

Writing the ode as

$$x^2y'' + (x^3+6x)\,y' + 6y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= x^3+6x \\ C &= 6 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2+14}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2+14 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2}{4} + \frac{7}{2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.461: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 2 \\ &= -2 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x}{2} + \frac{7}{2x} - \frac{49}{4x^3} + \frac{343}{4x^5} - \frac{12005}{16x^7} + \frac{117649}{16x^9} - \frac{2470629}{32x^{11}} + \frac{27176919}{32x^{13}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= \frac{x}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{x^2}{4}$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 + 14}{4} \\ &= Q + \frac{R}{4} \\ &= \left(\frac{x^2}{4} + \frac{7}{2}\right) + (0) \\ &= \frac{x^2}{4} + \frac{7}{2} \end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is $\frac{7}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(\frac{7}{2}\right) - (0) \\ &= \frac{7}{2} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{x}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{\frac{7}{2}}{\frac{1}{2}} - 1\right) &&= 3 \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{\frac{7}{2}}{\frac{1}{2}} - 1\right) &&= -4 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2}{4} + \frac{7}{2}$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-2	$\frac{x}{2}$	3	-4

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = 3$, and since there are no poles, then

$$\begin{aligned} d &= \alpha_\infty^+ \\ &= 3 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= (+)[\sqrt{r}]_\infty \\ &= 0 + \left(\frac{x}{2}\right) \\ &= \frac{x}{2} \\ &= \frac{x}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 3$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = x^3 + a_2 x^2 + a_1 x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (6x + 2a_2) + 2\left(\frac{x}{2}\right)(3x^2 + 2xa_2 + a_1) + \left(\left(\frac{1}{2}\right) + \left(\frac{x}{2}\right)^2 - \left(\frac{x^2}{4} + \frac{7}{2}\right)\right) &= 0 \\ -a_2 x^2 + (-2a_1 + 6)\, x - 3a_0 + 2a_2 &= 0 \end{aligned}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 0, a_1 = 3, a_2 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^3 + 3x$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= (x^3 + 3x)\, e^{\int \frac{x}{2} dx} \\ &= (x^3 + 3x)\, e^{\frac{x^2}{4}} \\ &= x(x^2 + 3)\, e^{\frac{x^2}{4}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{x^3+6x}{x^2} \, dx} \\ &= z_1 e^{-\frac{x^2}{4} - 3\ln(x)} \\ &= z_1 \left(\frac{e^{-\frac{x^2}{4}}}{x^3}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{x^2+3}{x^2}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{x^3+6x}{x^2}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-\frac{x^2}{2}-6\ln(x)}}{(y_1)^2}\, dx \\ &= y_1 \left(\int \frac{e^{-\frac{x^2}{2}-6\ln(x)} x^4}{(x^2+3)^2} dx \right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\frac{x^2+3}{x^2} \right) + c_2 \left(\frac{x^2+3}{x^2} \left(\int \frac{e^{-\frac{x^2}{2}-6\ln(x)} x^4}{(x^2+3)^2} dx \right) \right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2 \left(\frac{d^2}{dx^2} y(x) \right) + x(x^2+6) \left(\frac{d}{dx} y(x) \right) + 6y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2} y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2} y(x) = -\frac{6y(x)}{x^2} - \frac{(x^2+6)\left(\frac{d}{dx} y(x)\right)}{x}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2} y(x) + \frac{(x^2+6)\left(\frac{d}{dx} y(x)\right)}{x} + \frac{6y(x)}{x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

    $\left[P_2(x) = \frac{x^2+6}{x}, P_3(x) = \frac{6}{x^2} \right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left. (x \cdot P_2(x)) \right|_{x=0} = 6$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $\left. (x^2 \cdot P_3(x)) \right|_{x=0} = 6$

  ◦ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $x^2\left(\frac{d^2}{dx^2}y(x)\right) + x(x^2+6)\left(\frac{d}{dx}y(x)\right) + 6y(x) = 0$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m = 1..3$

  $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1+m}$

  ◦ Shift index using $k- >k+1-m$

  $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$

  ◦ Convert $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

  $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(3+r)\,(2+r)\, x^r + a_1(4+r)\,(3+r)\, x^{1+r} + \left(\sum_{k=2}^{\infty} (a_k(k+r+3)\,(k+r+2) + a_{k-2}(k-2+r))\, x^{k}\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(3+r)\,(2+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{-3, -2\}$

- Each term must be 0

  $a_1(4+r)\,(3+r) = 0$

- Solve for the dependent coefficient(s)

  $a_1 = 0$

- Each term in the series must be 0, giving the recursion relation

  $a_k(k+r+3)\,(k+r+2) + a_{k-2}(k-2+r) = 0$

- Shift index using $k- >k+2$

  $a_{k+2}(k+5+r)\,(k+4+r) + a_k(k+r) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{a_k(k+r)}{(k+5+r)(k+4+r)}$

- Recursion relation for $r = -3$

  $a_{k+2} = -\frac{a_k(k-3)}{(k+2)(k+1)}$

- Solution for $r = -3$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k-3}, a_{k+2} = -\frac{a_k(k-3)}{(k+2)(k+1)}, a_1 = 0\right]$

- Recursion relation for $r = -2$; series terminates at $k = 2$

  $a_{k+2} = -\frac{a_k(k-2)}{(k+3)(k+2)}$

- Solution for $r = -2$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k-2}, a_{k+2} = -\frac{a_k(k-2)}{(k+3)(k+2)}, a_1 = 0\right]$

- Combine solutions and rename parameters

  $\left[y(x) = \left(\sum_{k=0}^{\infty} a_k x^{k-3}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k-2}\right), a_{k+2} = -\frac{a_k(k-3)}{(k+2)(k+1)}, a_1 = 0, b_{k+2} = -\frac{b_k(k-2)}{(k+3)(k+2)}, b_1 = 0\right]$

2.1.242 Problem 245

Internal problem ID [9414]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 245
Date solved : `Monday, January 27, 2025 at 06:02:33 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' + x(1-x)\,y' - y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.217 (sec)

Writing the ode as

$$x^2y'' + \left(-x^2+x\right)y' - y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -x^2 + x \\ C &= -1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 - 2x + 3}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2 - 2x + 3 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2 - 2x + 3}{4x^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.463: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} - \frac{1}{2x} + \frac{3}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} - \frac{1}{2x} + \frac{1}{2x^2} + \frac{1}{2x^3} + \frac{1}{4x^4} - \frac{1}{4x^5} - \frac{3}{4x^6} - \frac{3}{4x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{2}\end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned}r &= \frac{s}{t} \\ &= \frac{x^2 - 2x + 3}{4x^2} \\ &= Q + \frac{R}{4x^2} \\ &= \left(\frac{1}{4}\right) + \left(\frac{-2x+3}{4x^2}\right) \\ &= \frac{1}{4} + \frac{-2x+3}{4x^2}\end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is -2. Dividing this by leading coefficient in t which is 4 gives $-\frac{1}{2}$. Now b can be found.

$$\begin{aligned}b &= \left(-\frac{1}{2}\right) - (0) \\ &= -\frac{1}{2}\end{aligned}$$

Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= \frac{1}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &&= -\frac{1}{2} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &&= \frac{1}{2}\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2 - 2x + 3}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	$-\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = -\frac{1}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^-\right) \\
&= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (+)[\sqrt{r}]_\infty \\
&= -\frac{1}{2x} + \left(\frac{1}{2}\right) \\
&= \frac{1}{2} - \frac{1}{2x} \\
&= \frac{x-1}{2x}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned}
(0) + 2\left(\frac{1}{2} - \frac{1}{2x}\right)(0) + \left(\left(\frac{1}{2x^2}\right) + \left(\frac{1}{2} - \frac{1}{2x}\right)^2 - \left(\frac{x^2-2x+3}{4x^2}\right) \right) &= 0 \\
0 &= 0
\end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= e^{\int \left(\frac{1}{2} - \frac{1}{2x}\right) dx} \\
&= \frac{e^{\frac{x}{2}}}{\sqrt{x}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-x^2+x}{x^2}\,dx} \\ &= z_1 e^{\frac{x}{2}-\frac{\ln(x)}{2}} \\ &= z_1\left(\frac{e^{\frac{x}{2}}}{\sqrt{x}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{e^x}{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-x^2+x}{x^2}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{x-\ln(x)}}{(y_1)^2}\,dx \\ &= y_1\left(-(1+x)\,x\,e^{x-\ln(x)}e^{-2x}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\frac{e^x}{x}\right) + c_2\left(\frac{e^x}{x}\left(-(1+x)\,x\,e^{x-\ln(x)}e^{-2x}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

Solve

$$x^2y'' - x(x+3)\, y' + 4y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.254 (sec)

Writing the ode as

$$x^2y'' + \left(-x^2-3x\right) y' + 4y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -x^2-3x \\ C &= 4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2+6x-1}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2+6x-1 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2+6x-1}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.465: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} - \frac{1}{4x^2} + \frac{3}{2x}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} + \frac{3}{2x} - \frac{5}{2x^2} + \frac{15}{2x^3} - \frac{115}{4x^4} + \frac{495}{4x^5} - \frac{2285}{4x^6} + \frac{11055}{4x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 + 6x - 1}{4x^2} \\ &= Q + \frac{R}{4x^2} \\ &= \left(\frac{1}{4}\right) + \left(\frac{6x - 1}{4x^2}\right) \\ &= \frac{1}{4} + \frac{6x - 1}{4x^2} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is 6. Dividing this by leading coefficient in t which is 4 gives $\frac{3}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(\frac{3}{2}\right) - (0) \\ &= \frac{3}{2} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{\frac{3}{2}}{\frac{1}{2}} - 0\right) &&= \frac{3}{2} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{\frac{3}{2}}{\frac{1}{2}} - 0\right) &&= -\frac{3}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2 + 6x - 1}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	$\frac{3}{2}$	$-\frac{3}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{3}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^+\right) \\
&= \frac{3}{2} - \left(\frac{1}{2}\right) \\
&= 1
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1} \right) + (+)[\sqrt{r}]_\infty \\
&= \frac{1}{2x} + \left(\frac{1}{2}\right) \\
&= \frac{1}{2x} + \frac{1}{2} \\
&= \frac{1+x}{2x}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{gathered}
(0) + 2\left(\frac{1}{2x} + \frac{1}{2}\right)(1) + \left(\left(-\frac{1}{2x^2}\right) + \left(\frac{1}{2x} + \frac{1}{2}\right)^2 - \left(\frac{x^2+6x-1}{4x^2}\right)\right) = 0 \\
\frac{1-a_0}{x} = 0
\end{gathered}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 1\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = 1 + x$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= (1+x)\, e^{\int \left(\frac{1}{2x}+\frac{1}{2}\right) dx} \\
&= (1+x)\, e^{\frac{x}{2}+\frac{\ln(x)}{2}} \\
&= (1+x)\sqrt{x}\, e^{\frac{x}{2}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-x^2-3x}{x^2}\, dx} \\
&= z_1 e^{\frac{x}{2}+\frac{3\ln(x)}{2}} \\
&= z_1 \left(x^{3/2} e^{\frac{x}{2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = x^2 e^x (1+x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-x^2-3x}{x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{x+3\ln(x)}}{(y_1)^2}\, dx \\
&= y_1 \left(-\frac{e^{-x}}{-1-x} - \mathrm{Ei}_1(x)\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(x^2 e^x (1+x)\right) + c_2 \left(x^2 e^x (1+x) \left(-\frac{e^{-x}}{-1-x} - \mathrm{Ei}_1(x)\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2 \left(\frac{d^2}{dx^2} y(x)\right) - x(x+3)\left(\frac{d}{dx} y(x)\right) + 4y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2} y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2} y(x) = -\frac{4y(x)}{x^2} + \frac{(x+3)\left(\frac{d}{dx} y(x)\right)}{x}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

$\frac{d^2}{dx^2}y(x) - \frac{(x+3)\left(\frac{d}{dx}y(x)\right)}{x} + \frac{4y(x)}{x^2} = 0$

- ☐ Check to see if $x_0 = 0$ is a regular singular point
  - ◦ Define functions

    $\left[P_2(x) = -\frac{x+3}{x}, P_3(x) = \frac{4}{x^2}\right]$
  - ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left(x \cdot P_2(x)\right)\bigg|_{x=0} = -3$
  - ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = 4$
  - ◦ $x = 0$is a regular singular point

    Check to see if $x_0 = 0$ is a regular singular point

    $x_0 = 0$
- • Multiply by denominators

  $x^2\left(\frac{d^2}{dx^2}y(x)\right) - x(x+3)\left(\frac{d}{dx}y(x)\right) + 4y(x) = 0$
- • Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$
- ☐ Rewrite ODE with series expansions
  - ◦ Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m = 1..2$

    $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1+m}$
  - ◦ Shift index using $k- >k+1-m$

    $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$
  - ◦ Convert $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

    $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, x^{k+r}$

    Rewrite ODE with series expansions

    $a_0(-2+r)^2 x^r + \left(\sum_{k=1}^{\infty} \left(a_k(k+r-2)^2 - a_{k-1}(k+r-1)\right) x^{k+r}\right) = 0$
- • $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-2+r)^2 = 0$
- • Values of r that satisfy the indicial equation

  $r = 2$
- • Each term in the series must be 0, giving the recursion relation

  $a_k(k+r-2)^2 - a_{k-1}(k+r-1) = 0$
- • Shift index using $k- >k+1$

  $a_{k+1}(k+r-1)^2 - a_k(k+r) = 0$
- • Recursion relation that defines series solution to ODE

  $a_{k+1} = \frac{a_k(k+r)}{(k+r-1)^2}$
- • Recursion relation for $r = 2$

  $a_{k+1} = \frac{a_k(k+2)}{(k+1)^2}$
- • Solution for $r = 2$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+2}, a_{k+1} = \frac{a_k(k+2)}{(k+1)^2}\right]$

Solve

$$x^2y'' - x^2y' - 2y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.228 (sec)

Writing the ode as

$$x^2y'' - x^2y' - 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -x^2 \\ C &= -2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 + 8}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2 + 8 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2 + 8}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.467: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} + \frac{2}{x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1 \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} + \frac{2}{x^2} - \frac{4}{x^4} + \frac{16}{x^6} - \frac{80}{x^8} + \frac{448}{x^{10}} - \frac{2688}{x^{12}} + \frac{16896}{x^{14}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 + 8}{4x^2} \\ &= Q + \frac{R}{4x^2} \\ &= \left(\frac{1}{4}\right) + \left(\frac{2}{x^2}\right) \\ &= \frac{1}{4} + \frac{2}{x^2} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is 0. Dividing this by leading coefficient in t which is 4 gives 0. Now b can be found.

$$\begin{aligned} b &= (0) - (0) \\ &= 0 \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{0}{\frac{1}{2}} - 0\right) &= 0 \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{0}{\frac{1}{2}} - 0\right) &= 0 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2 + 8}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	2	-1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	0	0

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 0$ then

$$\begin{aligned} d &= \alpha_\infty^- - (\alpha_{c_1}^-) \\ &= 0 - (-1) \\ &= 1 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= -\frac{1}{x} + (-)\left(\frac{1}{2}\right) \\ &= -\frac{1}{x} - \frac{1}{2} \\ &= -\frac{2+x}{2x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(-\frac{1}{x} - \frac{1}{2}\right)(1) + \left(\left(\frac{1}{x^2}\right) + \left(-\frac{1}{x} - \frac{1}{2}\right)^2 - \left(\frac{x^2+8}{4x^2}\right) \right) &= 0 \\ \frac{-2+a_0}{x} &= 0 \end{aligned}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 2\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = 2 + x$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= (2+x)\, e^{\int \left(-\frac{1}{x}-\frac{1}{2}\right) dx} \\
&= (2+x)\, e^{-\frac{x}{2}-\ln(x)} \\
&= \frac{(2+x)\, e^{-\frac{x}{2}}}{x}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-x^2}{x^2} \, dx} \\
&= z_1 e^{\frac{x}{2}} \\
&= z_1 \left(e^{\frac{x}{2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{2+x}{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-x^2}{x^2} \, dx}}{(y_1)^2} \, dx \\
&= y_1 \int \frac{e^{x}}{(y_1)^2} \, dx \\
&= y_1 \left(\frac{(-2+x)\, e^{x}}{2+x}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{2+x}{x}\right) + c_2 \left(\frac{2+x}{x} \left(\frac{(-2+x)\, e^{x}}{2+x}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2 \left(\frac{d^2}{dx^2} y(x)\right) - x^2 \left(\frac{d}{dx} y(x)\right) - 2y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2} y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2} y(x) = \frac{2y(x)}{x^2} + \frac{d}{dx} y(x)$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

$\frac{d^2}{dx^2}y(x) - \frac{d}{dx}y(x) - \frac{2y(x)}{x^2} = 0$

- □ Check to see if $x_0 = 0$ is a regular singular point
  - ◦ Define functions

    $\left[P_2(x) = -1, P_3(x) = -\frac{2}{x^2}\right]$
  - ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left(x \cdot P_2(x)\right)\Big|_{x=0} = 0$
  - ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $\left(x^2 \cdot P_3(x)\right)\Big|_{x=0} = -2$
  - ◦ $x = 0$is a regular singular point

    Check to see if $x_0 = 0$ is a regular singular point

    $x_0 = 0$
- Multiply by denominators

  $x^2\left(\frac{d^2}{dx^2}y(x)\right) - x^2\left(\frac{d}{dx}y(x)\right) - 2y(x) = 0$
- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$
- □ Rewrite ODE with series expansions
  - ◦ Convert $x^2 \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion

    $x^2 \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r+1}$
  - ◦ Shift index using $k- >k-1$

    $x^2 \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=1}^{\infty} a_{k-1}(k-1+r)\, x^{k+r}$
  - ◦ Convert $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

    $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k-1+r)\, x^{k+r}$

    Rewrite ODE with series expansions

    $a_0(1+r)\,(-2+r)\, x^r + \left(\sum_{k=1}^{\infty} \left(a_k(k+r+1)\,(k+r-2) - a_{k-1}(k-1+r)\right) x^{k+r}\right) = 0$
- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(1+r)\,(-2+r) = 0$
- Values of r that satisfy the indicial equation

  $r \in \{-1, 2\}$
- Each term in the series must be 0, giving the recursion relation

  $a_k(k+r+1)\,(k+r-2) - a_{k-1}(k-1+r) = 0$
- Shift index using $k- >k+1$

  $a_{k+1}(k+2+r)\,(k-1+r) - a_k(k+r) = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+1} = \frac{a_k(k+r)}{(k+2+r)(k-1+r)}$
- Recursion relation for $r = -1$; series terminates at $k = 1$

  $a_{k+1} = \frac{a_k(k-1)}{(k+1)(k-2)}$
- Apply recursion relation for $k = 0$

  $a_1 = \frac{a_0}{2}$
- Terminating series solution of the ODE for $r = -1$. Use reduction of order to find the second

  $y(x) = a_0 \cdot \left(1 + \frac{x}{2}\right)$
- Recursion relation for $r = 2$

$a_{k+1} = \frac{a_k(k+2)}{(k+4)(k+1)}$

- Solution for $r = 2$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+2}, a_{k+1} = \frac{a_k(k+2)}{(k+4)(k+1)}\right]$

- Combine solutions and rename parameters

  $\left[y(x) = a_0 \cdot \left(1 + \frac{x}{2}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+2}\right), b_{k+1} = \frac{b_k(k+2)}{(4+k)(k+1)}\right]$

2.1.245 Problem 248

Internal problem ID [9417]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 248
Date solved : `Monday, January 27, 2025 at 06:02:35 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' - x^2y' - (3x+2)\, y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.262 (sec)

Writing the ode as

$$x^2y'' - x^2y' + (-3x-2)\, y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -x^2 \\ C &= -3x-2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 + 12x + 8}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2 + 12x + 8 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2 + 12x + 8}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.469: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} + \frac{2}{x^2} + \frac{3}{x}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1 \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} + \frac{3}{x} - \frac{7}{x^2} + \frac{42}{x^3} - \frac{301}{x^4} + \frac{2394}{x^5} - \frac{20342}{x^6} + \frac{180852}{x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{2}\end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned}r &= \frac{s}{t} \\ &= \frac{x^2 + 12x + 8}{4x^2} \\ &= Q + \frac{R}{4x^2} \\ &= \left(\frac{1}{4}\right) + \left(\frac{12x + 8}{4x^2}\right) \\ &= \frac{1}{4} + \frac{12x + 8}{4x^2}\end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is 12. Dividing this by leading coefficient in t which is 4 gives 3. Now b can be found.

$$\begin{aligned}b &= (3) - (0) \\ &= 3\end{aligned}$$

Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= \frac{1}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{3}{\frac{1}{2}} - 0\right) &&= 3 \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{3}{\frac{1}{2}} - 0\right) &&= -3\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2 + 12x + 8}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	2	-1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	3	-3

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = 3$ then

$$\begin{aligned} d &= \alpha_\infty^+ - \left(\alpha_{c_1}^+\right) \\ &= 3 - (2) \\ &= 1 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1} \right) + (+)[\sqrt{r}]_\infty \\ &= \frac{2}{x} + \left(\frac{1}{2}\right) \\ &= \frac{2}{x} + \frac{1}{2} \\ &= \frac{4+x}{2x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(\frac{2}{x} + \frac{1}{2}\right)(1) + \left(\left(-\frac{2}{x^2}\right) + \left(\frac{2}{x} + \frac{1}{2}\right)^2 - \left(\frac{x^2+12x+8}{4x^2}\right) \right) &= 0 \\ \frac{4-a_0}{x} &= 0 \end{aligned}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 4\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = 4 + x$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= (4+x)\, e^{\int \left(\frac{2}{x}+\frac{1}{2}\right) dx} \\ &= (4+x)\, e^{\frac{x}{2}+2\ln(x)} \\ &= (4+x)\, x^2 e^{\frac{x}{2}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-x^2}{x^2} \, dx} \\ &= z_1 e^{\frac{x}{2}} \\ &= z_1 \left(e^{\frac{x}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = e^x (4+x)\, x^2$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-x^2}{x^2} \, dx}}{(y_1)^2} \, dx \\ &= y_1 \int \frac{e^x}{(y_1)^2} \, dx \\ &= y_1 \left(-\frac{e^{-x}(x^3+3x^2-2x+2)}{24\,(4+x)\, x^3} + \frac{\mathrm{Ei}_1(x)}{24} \right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(e^x (4+x)\, x^2\right) + c_2 \left(e^x (4+x)\, x^2 \left(-\frac{e^{-x}(x^3+3x^2-2x+2)}{24\,(4+x)\, x^3} + \frac{\mathrm{Ei}_1(x)}{24} \right) \right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$$y(x) \to e^x x^2(x+4) \left(c_2 \int_1^x \frac{e^{-K[1]}}{K[1]^4(K[1]+4)^2} dK[1] + c_1\right)$$

2.1.246 Problem 249

Internal problem ID [9418]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 249
Date solved : `Monday, January 27, 2025 at 06:02:36 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' + x(5-x)\,y' + 4y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.336 (sec)

Writing the ode as

$$x^2y'' + \left(-x^2+5x\right)y' + 4y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -x^2+5x \\ C &= 4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2-10x-1}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2-10x-1 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2-10x-1}{4x^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.471: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} - \frac{1}{4x^2} - \frac{5}{2x}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} - \frac{5}{2x} - \frac{13}{2x^2} - \frac{65}{2x^3} - \frac{819}{4x^4} - \frac{5785}{4x^5} - \frac{43797}{4x^6} - \frac{347425}{4x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 - 10x - 1}{4x^2} \\ &= Q + \frac{R}{4x^2} \\ &= \left(\frac{1}{4}\right) + \left(\frac{-10x - 1}{4x^2}\right) \\ &= \frac{1}{4} + \frac{-10x - 1}{4x^2} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is -10. Dividing this by leading coefficient in t which is 4 gives $-\frac{5}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{5}{2}\right) - (0) \\ &= -\frac{5}{2} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) = \frac{1}{2}\left(\frac{-\frac{5}{2}}{\frac{1}{2}} - 0\right) = -\frac{5}{2} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) = \frac{1}{2}\left(-\frac{-\frac{5}{2}}{\frac{1}{2}} - 0\right) = \frac{5}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2 - 10x - 1}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	$-\frac{5}{2}$	$\frac{5}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{5}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^+\right) \\ &= \frac{5}{2} - \left(\frac{1}{2}\right) \\ &= 2 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1}\right) + (-)[\sqrt{r}]_\infty \\ &= \frac{1}{2x} + (-)\left(\frac{1}{2}\right) \\ &= \frac{1}{2x} - \frac{1}{2} \\ &= -\frac{-1+x}{2x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 2$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x^2 + a_1 x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (2) + 2\left(\frac{1}{2x} - \frac{1}{2}\right)(2x + a_1) + \left(\left(-\frac{1}{2x^2}\right) + \left(\frac{1}{2x} - \frac{1}{2}\right)^2 - \left(\frac{x^2 - 10x - 1}{4x^2}\right)\right) &= 0 \\ \frac{(a_1 + 4)\, x + 2a_0 + a_1}{x} &= 0 \end{aligned}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 2, a_1 = -4\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^2 - 4x + 2$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= pe^{\int \omega\,dx} \\
&= \left(x^2 - 4x + 2\right) \mathrm{e}^{\int \left(\frac{1}{2x} - \frac{1}{2}\right)dx} \\
&= \left(x^2 - 4x + 2\right) \mathrm{e}^{-\frac{x}{2} + \frac{\ln(x)}{2}} \\
&= \left(x^2 - 4x + 2\right) \sqrt{x}\,\mathrm{e}^{-\frac{x}{2}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-x^2+5x}{x^2}\,dx} \\
&= z_1 e^{\frac{x}{2} - \frac{5\ln(x)}{2}} \\
&= z_1 \left(\frac{\mathrm{e}^{\frac{x}{2}}}{x^{5/2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{x^2 - 4x + 2}{x^2}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-x^2+5x}{x^2}\,dx}}{\left(y_1\right)^2}\,dx \\
&= y_1 \int \frac{e^{x - 5\ln(x)}}{\left(y_1\right)^2}\,dx \\
&= y_1 \left(-\frac{\mathrm{e}^x (x-3)}{4\left(x^2 - 4x + 2\right)} - \frac{\mathrm{Ei}_1(-x)}{4}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{x^2 - 4x + 2}{x^2}\right) + c_2 \left(\frac{x^2 - 4x + 2}{x^2}\left(-\frac{\mathrm{e}^x (x-3)}{4\left(x^2 - 4x + 2\right)} - \frac{\mathrm{Ei}_1(-x)}{4}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2\left(\frac{d^2}{dx^2}y(x)\right)+x(5-x)\left(\frac{d}{dx}y(x)\right)+4y(x)=0$

- Highest derivative means the order of the ODE is 2

$\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

$\frac{d^2}{dx^2}y(x)=-\frac{4y(x)}{x^2}+\frac{(x-5)\left(\frac{d}{dx}y(x)\right)}{x}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

$\frac{d^2}{dx^2}y(x)-\frac{(x-5)\left(\frac{d}{dx}y(x)\right)}{x}+\frac{4y(x)}{x^2}=0$

□ Check to see if $x_0=0$ is a regular singular point

  ◦ Define functions

  $\left[P_2(x)=-\frac{x-5}{x},P_3(x)=\frac{4}{x^2}\right]$

  ◦ $x\cdot P_2(x)$ is analytic at $x=0$

  $\left.(x\cdot P_2(x))\right|_{x=0}=5$

  ◦ $x^2\cdot P_3(x)$ is analytic at $x=0$

  $\left.(x^2\cdot P_3(x))\right|_{x=0}=4$

  ◦ $x=0$is a regular singular point

  Check to see if $x_0=0$ is a regular singular point

  $x_0=0$

- Multiply by denominators

$x^2\left(\frac{d^2}{dx^2}y(x)\right)-x(x-5)\left(\frac{d}{dx}y(x)\right)+4y(x)=0$

- Assume series solution for $y(x)$

$y(x)=\sum_{k=0}^{\infty}a_kx^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $x^m\cdot\left(\frac{d}{dx}y(x)\right)$ to series expansion for $m=1..2$

  $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,x^{k+r-1+m}$

  ◦ Shift index using $k->k+1-m$

  $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,x^{k+r}$

  ◦ Convert $x^2\cdot\left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

  $x^2\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(2+r)^2\,x^r+\left(\sum_{k=1}^{\infty}\left(a_k(k+r+2)^2-a_{k-1}(k+r-1)\right)x^{k+r}\right)=0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$(2+r)^2=0$

- Values of r that satisfy the indicial equation

$r=-2$

- Each term in the series must be 0, giving the recursion relation

$a_k(k+r+2)^2-a_{k-1}(k+r-1)=0$

- Shift index using $k->k+1$

$a_{k+1}(k+3+r)^2 - a_k(k+r) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+1} = \frac{a_k(k+r)}{(k+3+r)^2}$

- Recursion relation for $r = -2$; series terminates at $k = 2$

  $a_{k+1} = \frac{a_k(k-2)}{(k+1)^2}$

- Apply recursion relation for $k = 0$

  $a_1 = -2a_0$

- Apply recursion relation for $k = 1$

  $a_2 = -\frac{a_1}{4}$

- Express in terms of a_0

  $a_2 = \frac{a_0}{2}$

- Terminating series solution of the ODE for $r = -2$. Use reduction of order to find the second lin

  $y(x) = a_0 \cdot \left(1 - 2x + \frac{1}{2}x^2\right)$

2.1.247 Problem 250

Internal problem ID [9419]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 250
Date solved : `Monday, January 27, 2025 at 06:02:37 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$4x^2y'' + 4x(1-x)\,y' + (2x-9)\,y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.224 (sec)

Writing the ode as

$$4x^2y'' + \left(-4x^2+4x\right)y' + (2x-9)\,y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4x^2 \\ B &= -4x^2+4x \\ C &= 2x-9 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2-4x+8}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2-4x+8 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2-4x+8}{4x^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.473: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} - \frac{1}{x} + \frac{2}{x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1 \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} - \frac{1}{x} + \frac{1}{x^2} + \frac{2}{x^3} + \frac{3}{x^4} + \frac{2}{x^5} - \frac{6}{x^6} - \frac{28}{x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{2}\end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned}r &= \frac{s}{t} \\ &= \frac{x^2 - 4x + 8}{4x^2} \\ &= Q + \frac{R}{4x^2} \\ &= \left(\frac{1}{4}\right) + \left(\frac{-4x + 8}{4x^2}\right) \\ &= \frac{1}{4} + \frac{-4x + 8}{4x^2}\end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is -4. Dividing this by leading coefficient in t which is 4 gives -1. Now b can be found.

$$\begin{aligned}b &= (-1) - (0) \\ &= -1\end{aligned}$$

Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= \frac{1}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-1}{\frac{1}{2}} - 0\right) &&= -1 \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-1}{\frac{1}{2}} - 0\right) &&= 1\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2 - 4x + 8}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	2	-1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	-1	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = -1$ then

$$\begin{aligned} d &= \alpha_\infty^+ - \left(\alpha_{c_1}^-\right) \\ &= -1 - (-1) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (+)[\sqrt{r}]_\infty \\ &= -\frac{1}{x} + \left(\frac{1}{2}\right) \\ &= \frac{1}{2} - \frac{1}{x} \\ &= \frac{x-2}{2x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(\frac{1}{2} - \frac{1}{x}\right)(0) + \left(\left(\frac{1}{x^2}\right) + \left(\frac{1}{2} - \frac{1}{x}\right)^2 - \left(\frac{x^2 - 4x + 8}{4x^2}\right)\right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= e^{\int \left(\frac{1}{2} - \frac{1}{x}\right) dx} \\ &= \frac{e^{\frac{x}{2}}}{x} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-4x^2+4x}{4x^2}\,dx} \\ &= z_1 e^{\frac{x}{2}-\frac{\ln(x)}{2}} \\ &= z_1\left(\frac{e^{\frac{x}{2}}}{\sqrt{x}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{e^{x}}{x^{3/2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-4x^2+4x}{4x^2}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{x-\ln(x)}}{(y_1)^2}\,dx \\ &= y_1\left(-\left(x^2+2x+2\right) x\, e^{x-\ln(x)} e^{-2x}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\frac{e^{x}}{x^{3/2}}\right) + c_2\left(\frac{e^{x}}{x^{3/2}}\left(-\left(x^2+2x+2\right) x\, e^{x-\ln(x)} e^{-2x}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$4x^2\left(\frac{d^2}{dx^2}y(x)\right) + 4x(1-x)\left(\frac{d}{dx}y(x)\right) + (2x-9)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{(2x-9)y(x)}{4x^2} + \frac{\left(\frac{d}{dx}y(x)\right)(x-1)}{x}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x) - \frac{\left(\frac{d}{dx}y(x)\right)(x-1)}{x} + \frac{(2x-9)y(x)}{4x^2} = 0$

☐ Check to see if $x_0 = 0$ is a regular singular point

  - Define functions

    $\left[P_2(x) = -\frac{x-1}{x}, P_3(x) = \frac{2x-9}{4x^2}\right]$

  - $x \cdot P_2(x)$ is analytic at $x = 0$

$\left(x \cdot P_2(x)\right)\Big|_{x=0} = 1$

- $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $\left(x^2 \cdot P_3(x)\right)\Big|_{x=0} = -\frac{9}{4}$

- $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $4x^2\left(\frac{d^2}{dx^2}y(x)\right) - 4x(x-1)\left(\frac{d}{dx}y(x)\right) + (2x-9)\,y(x) = 0$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

- Rewrite ODE with series expansions

  - Convert $x^m \cdot y(x)$ to series expansion for $m = 0..1$

    $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

  - Shift index using $k- >k - m$

    $x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

  - Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m = 1..2$

    $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1+m}$

  - Shift index using $k- >k + 1 - m$

    $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$

  - Convert $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

    $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(3+2r)\,(-3+2r)\, x^r + \left(\sum_{k=1}^{\infty} \left(a_k(2k+2r+3)\,(2k+2r-3) - 2a_{k-1}(2k+2r-3)\right) x^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(3+2r)\,(-3+2r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \left\{-\frac{3}{2}, \frac{3}{2}\right\}$

- Each term in the series must be 0, giving the recursion relation

  $4\left(\left(k+r+\frac{3}{2}\right) a_k - a_{k-1}\right)\left(k+r-\frac{3}{2}\right) = 0$

- Shift index using $k- >k + 1$

  $4\left(\left(k+\frac{5}{2}+r\right) a_{k+1} - a_k\right)\left(k-\frac{1}{2}+r\right) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+1} = \frac{2a_k}{2k+5+2r}$

- Recursion relation for $r = -\frac{3}{2}$

  $a_{k+1} = \frac{2a_k}{2k+2}$

- Solution for $r = -\frac{3}{2}$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k-\frac{3}{2}}, a_{k+1} = \frac{2a_k}{2k+2}\right]$

- Recursion relation for $r = \frac{3}{2}$

$a_{k+1} = \frac{2a_k}{2k+8}$

- Solution for $r = \frac{3}{2}$

$$\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+\frac{3}{2}}, a_{k+1} = \frac{2a_k}{2k+8}\right]$$

- Combine solutions and rename parameters

$$\left[y(x) = \left(\sum_{k=0}^{\infty} a_k x^{k-\frac{3}{2}}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{3}{2}}\right), a_{k+1} = \frac{2a_k}{2k+2}, b_{k+1} = \frac{2b_k}{2k+8}\right]$$

2.1.248 Problem 251

Internal problem ID [9420]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 251
Date solved : `Monday, January 27, 2025 at 06:02:37 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' + 2x(2+x)\,y' + 2(1+x)\,y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.250 (sec)

Writing the ode as

$$x^2y'' + \left(2x^2+4x\right)y' + (2x+2)\,y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= 2x^2+4x \\ C &= 2x+2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{2+x}{x} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 2+x \\ t &= x \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{2+x}{x}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.475: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 1 - 1 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = x$. There is a pole at $x = 0$ of order 1. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 1. For the pole at $x = 0$ of order 1 then

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= 1 \\ \alpha_c^- &= 1 \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx 1 + \frac{1}{x} - \frac{1}{2x^2} + \frac{1}{2x^3} - \frac{5}{8x^4} + \frac{7}{8x^5} - \frac{21}{16x^6} + \frac{33}{16x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = 1$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= 1 \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = 1$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2+x}{x} \\ &= Q + \frac{R}{x} \\ &= (1) + \left(\frac{2}{x}\right) \\ &= 1 + \frac{2}{x} \end{aligned}$$

Since the degree of t is 1, then we see that the coefficient of the term 1 in the remainder R is 2. Dividing this by leading coefficient in t which is 1 gives 2. Now b can be found.

$$\begin{aligned} b &= (2) - (0) \\ &= 2 \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= 1 \\ \alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{2}{1} - 0\right) &= 1 \\ \alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{2}{1} - 0\right) &= -1 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{2+x}{x}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	1	0	0	1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
0	1	1	-1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{+} = 1$ then

$$\begin{aligned} d &= \alpha_\infty^{+} - \left(\alpha_{c_1}^{-}\right) \\ &= 1 - (1) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x-c_1} \right) + (+)[\sqrt{r}]_\infty \\ &= \frac{1}{x} + (1) \\ &= 1 + \frac{1}{x} \\ &= 1 + \frac{1}{x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(1 + \frac{1}{x}\right)(0) + \left(\left(-\frac{1}{x^2}\right) + \left(1 + \frac{1}{x}\right)^2 - \left(\frac{2+x}{x}\right) \right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega\, dx} \\ &= e^{\int \left(1 + \frac{1}{x}\right) dx} \\ &= x\, e^{x} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2} \frac{2x^2+4x}{x^2}\, dx} \\ &= z_1 e^{-x - 2\ln(x)} \\ &= z_1 \left(\frac{e^{-x}}{x^2}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{1}{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{2x^2+4x}{x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-2x-4\ln(x)}}{(y_1)^2}\, dx \\
&= y_1 \left(-\frac{e^{-2x}}{3x} + \frac{e^{-2x}}{3} - \frac{2x\, e^{-2x}}{3} + \frac{4x^2\, \mathrm{Ei}_1(2x)}{3} \right. \\
&\quad \left. - \frac{4\, \mathrm{Ei}_1(2x)\, x^3 - 2\, e^{-2x} x^2 + x\, e^{-2x} - 6x\, \mathrm{Ei}_1(2x) + 2\, e^{-2x}}{3x}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{1}{x}\right) + c_2 \left(\frac{1}{x}\left(-\frac{e^{-2x}}{3x} + \frac{e^{-2x}}{3} - \frac{2x\, e^{-2x}}{3} + \frac{4x^2\, \mathrm{Ei}_1(2x)}{3} \right.\right. \\
&\quad \left.\left. - \frac{4\, \mathrm{Ei}_1(2x)\, x^3 - 2\, e^{-2x} x^2 + x\, e^{-2x} - 6x\, \mathrm{Ei}_1(2x) + 2\, e^{-2x}}{3x}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

2.1.249 Problem 252

Internal problem ID [9421]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 252
Date solved : `Monday, January 27, 2025 at 06:02:38 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' - x(1-x)\,y' + (1-x)\,y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.243 (sec)

Writing the ode as

$$x^2y'' + \left(x^2-x\right)y' + (1-x)\,y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= x^2-x \\ C &= 1-x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2+2x-1}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2+2x-1 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2+2x-1}{4x^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.476: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} + \frac{1}{2x} - \frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} + \frac{1}{2x} - \frac{1}{2x^2} + \frac{1}{2x^3} - \frac{3}{4x^4} + \frac{5}{4x^5} - \frac{9}{4x^6} + \frac{17}{4x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{2}\end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned}r &= \frac{s}{t} \\ &= \frac{x^2 + 2x - 1}{4x^2} \\ &= Q + \frac{R}{4x^2} \\ &= \left(\frac{1}{4}\right) + \left(\frac{2x - 1}{4x^2}\right) \\ &= \frac{1}{4} + \frac{2x - 1}{4x^2}\end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is 2. Dividing this by leading coefficient in t which is 4 gives $\frac{1}{2}$. Now b can be found.

$$\begin{aligned}b &= \left(\frac{1}{2}\right) - (0) \\ &= \frac{1}{2}\end{aligned}$$

Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= \frac{1}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) = \frac{1}{2}\left(\frac{\frac{1}{2}}{\frac{1}{2}} - 0\right) = \frac{1}{2} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) = \frac{1}{2}\left(-\frac{\frac{1}{2}}{\frac{1}{2}} - 0\right) = -\frac{1}{2}\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2 + 2x - 1}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	$\frac{1}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^+ - \left(\alpha_{c_1}^+\right) \\ &= \frac{1}{2} - \left(\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1} \right) + (+)[\sqrt{r}]_\infty \\ &= \frac{1}{2x} + \left(\frac{1}{2}\right) \\ &= \frac{1}{2} + \frac{1}{2x} \\ &= \frac{x+1}{2x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(\frac{1}{2} + \frac{1}{2x}\right)(0) + \left(\left(-\frac{1}{2x^2}\right) + \left(\frac{1}{2} + \frac{1}{2x}\right)^2 - \left(\frac{x^2+2x-1}{4x^2}\right)\right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= e^{\int \left(\frac{1}{2} + \frac{1}{2x}\right) dx} \\ &= \sqrt{x}\, e^{\frac{x}{2}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{x^2-x}{x^2}\,dx} \\ &= z_1 e^{-\frac{x}{2}+\frac{\ln(x)}{2}} \\ &= z_1\left(\sqrt{x}\,\mathrm{e}^{-\frac{x}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = x$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{x^2-x}{x^2}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{-x+\ln(x)}}{(y_1)^2}\,dx \\ &= y_1(-\operatorname{Ei}_1(x)) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(x) + c_2(x(-\operatorname{Ei}_1(x))) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2\left(\frac{d^2}{dx^2}y(x)\right) - x(1-x)\left(\frac{d}{dx}y(x)\right) + (1-x)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = \frac{(x-1)y(x)}{x^2} - \frac{\left(\frac{d}{dx}y(x)\right)(x-1)}{x}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x) + \frac{\left(\frac{d}{dx}y(x)\right)(x-1)}{x} - \frac{(x-1)y(x)}{x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  ○ Define functions

  $\left[P_2(x) = \frac{x-1}{x}, P_3(x) = -\frac{x-1}{x^2}\right]$

  ○ $x \cdot P_2(x)$ is analytic at $x = 0$

  $\left.(x \cdot P_2(x))\right|_{x=0} = -1$

  ○ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

$\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = 1$

- $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $x^2\left(\frac{d^2}{dx^2}y(x)\right) + x(x-1)\left(\frac{d}{dx}y(x)\right) + (1-x)\,y(x) = 0$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

- Convert $x^m \cdot y(x)$ to series expansion for $m = 0..1$

  $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- Shift index using $k->k-m$

  $x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m = 1..2$

  $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$

- Shift index using $k->k+1-m$

  $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$

- Convert $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

  $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(-1+r)^2\,x^r + \left(\sum_{k=1}^{\infty}\left(a_k(k+r-1)^2 + a_{k-1}(k-2+r)\right)x^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-1+r)^2 = 0$

- Values of r that satisfy the indicial equation

  $r = 1$

- Each term in the series must be 0, giving the recursion relation

  $a_k(k+r-1)^2 + a_{k-1}(k-2+r) = 0$

- Shift index using $k->k+1$

  $a_{k+1}(k+r)^2 + a_k(k+r-1) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+1} = -\frac{a_k(k+r-1)}{(k+r)^2}$

- Recursion relation for $r = 1$

  $a_{k+1} = -\frac{a_k k}{(k+1)^2}$

- Solution for $r = 1$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+1}, a_{k+1} = -\frac{a_k k}{(k+1)^2}\right]$

2.1.250 Problem 253

Internal problem ID [9422]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 253
Date solved : `Monday, January 27, 2025 at 06:02:39 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$4x^2y'' + 4x(1+2x)\,y' + (4x-1)\,y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.101 (sec)

Writing the ode as

$$4x^2y'' + \left(8x^2+4x\right)y' + (4x-1)\,y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4x^2 \\ B &= 8x^2+4x \\ C &= 4x-1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.478: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{8x^2+4x}{4x^2}\, dx} \\ &= z_1 e^{-x-\frac{\ln(x)}{2}} \\ &= z_1 \left(\frac{\mathrm{e}^{-x}}{\sqrt{x}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{\mathrm{e}^{-2x}}{\sqrt{x}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{8x^2+4x}{4x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-2x-\ln(x)}}{(y_1)^2}\,dx \\
&= y_1 \left(\frac{e^{-2x-\ln(x)} x\, e^{4x}}{2}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{e^{-2x}}{\sqrt{x}}\right) + c_2 \left(\frac{e^{-2x}}{\sqrt{x}} \left(\frac{e^{-2x-\ln(x)} x\, e^{4x}}{2}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

2.1.251 Problem 254

Internal problem ID [9423]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 254
Date solved : `Monday, January 27, 2025 at 06:02:39 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' + x(4+x)\,y' + (2+x)\,y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.251 (sec)

Writing the ode as

$$x^2y'' + \left(x^2+4x\right)y' + (2+x)\,y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= x^2+4x \\ C &= 2+x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{4+x}{4x} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 4+x \\ t &= 4x \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{4+x}{4x}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.480: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 1 - 1 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x$. There is a pole at $x = 0$ of order 1. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 1. For the pole at $x = 0$ of order 1 then

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= 1 \\ \alpha_c^- &= 1 \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} + \frac{1}{x} - \frac{1}{x^2} + \frac{2}{x^3} - \frac{5}{x^4} + \frac{14}{x^5} - \frac{42}{x^6} + \frac{132}{x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{4+x}{4x} \\ &= Q + \frac{R}{4x} \\ &= \left(\frac{1}{4}\right) + \left(\frac{1}{x}\right) \\ &= \frac{1}{4} + \frac{1}{x} \end{aligned}$$

Since the degree of t is 1, then we see that the coefficient of the term 1 in the remainder R is 4. Dividing this by leading coefficient in t which is 4 gives 1. Now b can be found.

$$\begin{aligned} b &= (1) - (0) \\ &= 1 \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{1}{\frac{1}{2}} - 0\right) &= 1 \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{1}{\frac{1}{2}} - 0\right) &= -1 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{4+x}{4x}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	1	0	0	1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	1	-1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = 1$ then

$$\begin{aligned} d &= \alpha_\infty^+ - \left(\alpha_{c_1}^-\right) \\ &= 1 - (1) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (+)[\sqrt{r}]_\infty \\ &= \frac{1}{x} + \left(\frac{1}{2}\right) \\ &= \frac{1}{2} + \frac{1}{x} \\ &= \frac{1}{2} + \frac{1}{x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(\frac{1}{2} + \frac{1}{x}\right)(0) + \left(\left(-\frac{1}{x^2}\right) + \left(\frac{1}{2} + \frac{1}{x}\right)^2 - \left(\frac{4+x}{4x}\right)\right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega\, dx} \\ &= e^{\int \left(\frac{1}{2} + \frac{1}{x}\right) dx} \\ &= x\, e^{\frac{x}{2}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{x^2+4x}{x^2}\, dx} \\ &= z_1 e^{-\frac{x}{2} - 2\ln(x)} \\ &= z_1 \left(\frac{e^{-\frac{x}{2}}}{x^2}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{1}{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x^2+4x}{x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-x-4\ln(x)}}{(y_1)^2}\, dx \\
&= y_1 \left(-\frac{e^{-x}}{3x} + \frac{e^{-x}}{6} - \frac{x\,e^{-x}}{6} + \frac{x^2\,\mathrm{Ei}_1(x)}{6} - \frac{\mathrm{Ei}_1(x)\,x^3 - e^{-x}x^2 - 6x\,\mathrm{Ei}_1(x) + x\,e^{-x} + 4\,e^{-x}}{6x}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{1}{x}\right) + c_2\left(\frac{1}{x}\left(-\frac{e^{-x}}{3x} + \frac{e^{-x}}{6} - \frac{x\,e^{-x}}{6} + \frac{x^2\,\mathrm{Ei}_1(x)}{6}\right.\right. \\
&\qquad \left.\left. - \frac{\mathrm{Ei}_1(x)\,x^3 - e^{-x}x^2 - 6x\,\mathrm{Ei}_1(x) + x\,e^{-x} + 4\,e^{-x}}{6x}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

2.1.252 Problem 255

Internal problem ID [9424]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 255
Date solved : `Monday, January 27, 2025 at 06:02:40 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' + xy' + \left(x^2 - \frac{9}{4}\right) y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.279 (sec)

Writing the ode as

$$x^2y'' + xy' + \left(x^2 - \frac{9}{4}\right) y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= x \\ C &= x^2 - \frac{9}{4} \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-x^2 + 2}{x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -x^2 + 2 \\ t &= x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{-x^2+2}{x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.481: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -1 + \frac{2}{x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1 \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx i - \frac{i}{x^2} - \frac{i}{2x^4} - \frac{i}{2x^6} - \frac{5i}{8x^8} - \frac{7i}{8x^{10}} - \frac{21i}{16x^{12}} - \frac{33i}{16x^{14}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = i$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= i \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = -1$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{-x^2+2}{x^2} \\ &= Q + \frac{R}{x^2} \\ &= (-1) + \left(\frac{2}{x^2}\right) \\ &= -1 + \frac{2}{x^2} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is 0. Dividing this by leading coefficient in t which is 1 gives 0. Now b can be found.

$$\begin{aligned} b &= (0) - (0) \\ &= 0 \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= i \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{0}{i} - 0\right) &&= 0 \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{0}{i} - 0\right) &&= 0 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{-x^2+2}{x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	2	-1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	i	0	0

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 0$ then

$$\begin{aligned} d &= \alpha_\infty^- - (\alpha_{c_1}^-) \\ &= 0 - (-1) \\ &= 1 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= -\frac{1}{x} + (-)(i) \\ &= -\frac{1}{x} - i \\ &= -\frac{1}{x} - i \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{gathered} (0) + 2\left(-\frac{1}{x} - i\right)(1) + \left(\left(\frac{1}{x^2}\right) + \left(-\frac{1}{x} - i\right)^2 - \left(\frac{-x^2+2}{x^2}\right) \right) = 0 \\ \frac{2ia_0 - 2}{x} = 0 \end{gathered}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = -i\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x - i$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= (x - i)\, \mathrm{e}^{\int \left(-\frac{1}{x} - i\right) dx} \\ &= (x - i)\, \mathrm{e}^{-\ln(x) - ix} \\ &= \frac{(x - i)\, \mathrm{e}^{-ix}}{x} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2} \frac{x}{x^2} \, dx} \\ &= z_1 e^{-\frac{\ln(x)}{2}} \\ &= z_1 \left(\frac{1}{\sqrt{x}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{(x - i)\, \mathrm{e}^{-ix}}{x^{3/2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{x}{x^2} \, dx}}{(y_1)^2} \, dx \\ &= y_1 \int \frac{e^{-\ln(x)}}{(y_1)^2} \, dx \\ &= y_1 \left(\frac{(ix - 1)\, \mathrm{e}^{2ix}}{-2x + 2i}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\frac{(x - i)\, \mathrm{e}^{-ix}}{x^{3/2}}\right) + c_2 \left(\frac{(x - i)\, \mathrm{e}^{-ix}}{x^{3/2}} \left(\frac{(ix - 1)\, \mathrm{e}^{2ix}}{-2x + 2i}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2\left(\frac{d^2}{dx^2}y(x)\right)+x\left(\frac{d}{dx}y(x)\right)+\left(x^2-\frac{9}{4}\right)y(x)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x)=-\frac{(4x^2-9)y(x)}{4x^2}-\frac{\frac{d}{dx}y(x)}{x}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x)+\frac{\frac{d}{dx}y(x)}{x}+\frac{(4x^2-9)y(x)}{4x^2}=0$

- ☐ Check to see if $x_0=0$ is a regular singular point
  - Define functions

    $\left[P_2(x)=\frac{1}{x}, P_3(x)=\frac{4x^2-9}{4x^2}\right]$
  - $x\cdot P_2(x)$ is analytic at $x=0$

    $(x\cdot P_2(x))\bigg|_{x=0}=1$
  - $x^2\cdot P_3(x)$ is analytic at $x=0$

    $(x^2\cdot P_3(x))\bigg|_{x=0}=-\frac{9}{4}$
  - $x=0$is a regular singular point

  Check to see if $x_0=0$ is a regular singular point

  $x_0=0$

- Multiply by denominators

  $4x^2\left(\frac{d^2}{dx^2}y(x)\right)+4x\left(\frac{d}{dx}y(x)\right)+(4x^2-9)y(x)=0$

- Assume series solution for $y(x)$

  $y(x)=\sum_{k=0}^{\infty}a_k x^{k+r}$

- ☐ Rewrite ODE with series expansions
  - Convert $x^m\cdot y(x)$ to series expansion for $m=0..2$

    $x^m\cdot y(x)=\sum_{k=0}^{\infty}a_k x^{k+r+m}$
  - Shift index using $k->k-m$

    $x^m\cdot y(x)=\sum_{k=m}^{\infty}a_{k-m}x^{k+r}$
  - Convert $x\cdot\left(\frac{d}{dx}y(x)\right)$ to series expansion

    $x\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,x^{k+r}$
  - Convert $x^2\cdot\left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

    $x^2\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)(k+r-1)\,x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(3+2r)(-3+2r)x^r+a_1(5+2r)(-1+2r)x^{1+r}+\left(\sum_{k=2}^{\infty}(a_k(2k+2r+3)(2k+2r-3)+4a_{\ldots}\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(3+2r)(-3+2r)=0$

- Values of r that satisfy the indicial equation

  $r\in\left\{-\frac{3}{2},\frac{3}{2}\right\}$

- Each term must be 0
  $a_1(5+2r)(-1+2r)=0$
- Solve for the dependent coefficient(s)
  $a_1=0$
- Each term in the series must be 0, giving the recursion relation
  $a_k(4k^2+8kr+4r^2-9)+4a_{k-2}=0$
- Shift index using $k->k+2$
  $a_{k+2}\left(4(k+2)^2+8(k+2)r+4r^2-9\right)+4a_k=0$
- Recursion relation that defines series solution to ODE
  $a_{k+2}=-\frac{4a_k}{4k^2+8kr+4r^2+16k+16r+7}$
- Recursion relation for $r=-\frac{3}{2}$
  $a_{k+2}=-\frac{4a_k}{4k^2+4k-8}$
- Solution for $r=-\frac{3}{2}$
  $\left[y(x)=\sum_{k=0}^{\infty}a_k x^{k-\frac{3}{2}}, a_{k+2}=-\frac{4a_k}{4k^2+4k-8}, a_1=0\right]$
- Recursion relation for $r=\frac{3}{2}$

2.1.253 Problem 256

Internal problem ID [9425]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 256
Date solved : `Monday, January 27, 2025 at 06:02:41 PM`
CAS classification : `[_Lienard]`

Solve

$$xy'' + 2y' + xy = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.123 (sec)

Writing the ode as

$$xy'' + 2y' + xy = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x \\ B &= 2 \\ C &= x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.483: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{2}{x}\, dx} \\ &= z_1 e^{-\ln(x)} \\ &= z_1 \left(\frac{1}{x}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{\cos(x)}{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{2}{x} dx}}{(y_1)^2} dx \\ &= y_1 \int \frac{e^{-2\ln(x)}}{(y_1)^2} dx \\ &= y_1(\tan(x)) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\frac{\cos(x)}{x}\right) + c_2 \left(\frac{\cos(x)}{x}(\tan(x))\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve
$\left(\frac{d^2}{dx^2}y(x)\right)x + 2\frac{d}{dx}y(x) + xy(x) = 0$

- Highest derivative means the order of the ODE is 2
  $\frac{d^2}{dx^2}y(x)$
- Isolate 2nd derivative
  $\frac{d^2}{dx^2}y(x) = -y(x) - \frac{2\left(\frac{d}{dx}y(x)\right)}{x}$
- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea
  $\frac{d^2}{dx^2}y(x) + \frac{2\left(\frac{d}{dx}y(x)\right)}{x} + y(x) = 0$

    $\left.(x \cdot P_2(x))\right|_{x=0} = 2$
  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$
    $\left.(x^2 \cdot P_3(x))\right|_{x=0} = 0$
  - $x = 0$is a regular singular point
    Check to see if $x_0 = 0$ is a regular singular point
    $x_0 = 0$
- Multiply by denominators
  $\left(\frac{d^2}{dx^2}y(x)\right)x + 2\frac{d}{dx}y(x) + xy(x) = 0$
- Assume series solution for $y(x)$
  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$
- ☐ Rewrite ODE with series expansions
  - Convert $x \cdot y(x)$ to series expansion
    $x \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+1}$
  - Shift index using $k- >k-1$

$x \cdot y(x) = \sum_{k=1}^{\infty} a_{k-1} x^{k+r}$

- Convert $\frac{d}{dx}y(x)$ to series expansion

  $\frac{d}{dx}y(x) = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r-1}$

- Shift index using $k->k+1$

  $\frac{d}{dx}y(x) = \sum_{k=-1}^{\infty} a_{k+1}(k+r+1)\, x^{k+r}$

- Convert $x \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

  $x \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r-1}$

- Shift index using $k->k+1$

  $x \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=-1}^{\infty} a_{k+1}(k+r+1)\,(k+r)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0 r(1+r)\, x^{-1+r} + a_1(1+r)\,(2+r)\, x^r + \left(\sum_{k=1}^{\infty} \left(a_{k+1}(k+r+1)\,(k+2+r) + a_{k-1}\right) x^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r(1+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{-1, 0\}$

- Each term must be 0

  $a_1(1+r)\,(2+r) = 0$

- Each term in the series must be 0, giving the recursion relation

  $a_{k+1}(k+r+1)\,(k+2+r) + a_{k-1} = 0$

- Shift index using $k->k+1$

  $a_{k+2}(k+2+r)\,(k+3+r) + a_k = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{a_k}{(k+2+r)(k+3+r)}$

- Recursion relation for $r = -1$

  $a_{k+2} = -\frac{a_k}{(k+1)(k+2)}$

- Solution for $r = -1$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k-1}, a_{k+2} = -\frac{a_k}{(k+1)(k+2)}, 0 = 0\right]$

- Recursion relation for $r = 0$

  $a_{k+2} = -\frac{a_k}{(k+2)(k+3)}$

- Solution for $r = 0$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^k, a_{k+2} = -\frac{a_k}{(k+2)(k+3)}, 2a_1 = 0\right]$

- Combine solutions and rename parameters

  $\left[y(x) = \left(\sum_{k=0}^{\infty} a_k x^{k-1}\right) + \left(\sum_{k=0}^{\infty} b_k x^k\right), a_{k+2} = -\frac{a_k}{(k+1)(k+2)}, 0 = 0, b_{k+2} = -\frac{b_k}{(k+2)(k+3)}, 2b_1 = 0\right]$

2.1.254 Problem 257

Internal problem ID [9426]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 257
Date solved : `Monday, January 27, 2025 at 06:02:41 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$2xy'' + 5(1-2x)\,y' - 5y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.421 (sec)

Writing the ode as

$$2xy'' + (-10x+5)\,y' - 5y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2x \\ B &= -10x+5 \\ C &= -5 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{100x^2 - 60x + 5}{16x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 100x^2 - 60x + 5 \\ t &= 16x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{100x^2 - 60x + 5}{16x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.485: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{25}{4} - \frac{15}{4x} + \frac{5}{16x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{5}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{4} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{5}{2} - \frac{3}{4x} - \frac{1}{20x^2} - \frac{3}{200x^3} - \frac{1}{200x^4} - \frac{9}{5000x^5} - \frac{137}{200000x^6} - \frac{543}{2000000x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{5}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{5}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{25}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{100x^2 - 60x + 5}{16x^2} \\ &= Q + \frac{R}{16x^2} \\ &= \left(\frac{25}{4}\right) + \left(\frac{-60x + 5}{16x^2}\right) \\ &= \frac{25}{4} + \frac{-60x + 5}{16x^2} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is -60. Dividing this by leading coefficient in t which is 16 gives $-\frac{15}{4}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{15}{4}\right) - (0) \\ &= -\frac{15}{4} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{5}{2} \\ \alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{15}{4}}{\frac{5}{2}} - 0\right) &&= -\frac{3}{4} \\ \alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{15}{4}}{\frac{5}{2}} - 0\right) &&= \frac{3}{4} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{100x^2 - 60x + 5}{16x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{5}{4}$	$-\frac{1}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{5}{2}$	$-\frac{3}{4}$	$\frac{3}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{3}{4}$ then

$$\begin{aligned} d &= \alpha_\infty^- - (\alpha_{c_1}^-) \\ &= \frac{3}{4} - \left(-\frac{1}{4}\right) \\ &= 1 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= -\frac{1}{4x} + (-)\left(\frac{5}{2}\right) \\ &= -\frac{1}{4x} - \frac{5}{2} \\ &= -\frac{1}{4x} - \frac{5}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{4x} - \frac{5}{2}\right)(1) + \left(\left(\frac{1}{4x^2}\right) + \left(-\frac{1}{4x} - \frac{5}{2}\right)^2 - \left(\frac{100x^2 - 60x + 5}{16x^2}\right) \right) = 0$$

$$\frac{-1 + 10a_0}{2x} = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\left\{ a_0 = \frac{1}{10} \right\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x + \frac{1}{10}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= \left(x + \frac{1}{10}\right) e^{\int \left(-\frac{1}{4x} - \frac{5}{2}\right) dx} \\ &= \left(x + \frac{1}{10}\right) e^{-\frac{5x}{2} - \frac{\ln(x)}{4}} \\ &= \frac{(1 + 10x)\, e^{-\frac{5x}{2}}}{10 x^{1/4}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2} \frac{-10x+5}{2x} \, dx} \\ &= z_1 e^{\frac{5x}{2} - \frac{5 \ln(x)}{4}} \\ &= z_1 \left(\frac{e^{\frac{5x}{2}}}{x^{5/4}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{1 + 10x}{10 x^{3/2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-10x+5}{2x} \, dx}}{(y_1)^2} \, dx \\ &= y_1 \int \frac{e^{5x - \frac{5 \ln(x)}{2}}}{(y_1)^2} \, dx \\ &= y_1 \left(\int \frac{100\, e^{5x - \frac{5 \ln(x)}{2}} x^3}{(1 + 10x)^2} \, dx \right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\frac{1 + 10x}{10 x^{3/2}}\right) + c_2 \left(\frac{1 + 10x}{10 x^{3/2}} \left(\int \frac{100\, e^{5x - \frac{5 \ln(x)}{2}} x^3}{(1 + 10x)^2} \, dx \right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$2\left(\frac{d^2}{dx^2}y(x)\right)x + 5(-2x+1)\left(\frac{d}{dx}y(x)\right) - 5y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = \frac{5y(x)}{2x} + \frac{5(2x-1)\left(\frac{d}{dx}y(x)\right)}{2x}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x) - \frac{5(2x-1)\left(\frac{d}{dx}y(x)\right)}{2x} - \frac{5y(x)}{2x} = 0$

- ☐ Check to see if $x_0 = 0$ is a regular singular point
  - Define functions

    $\left[P_2(x) = -\frac{5(2x-1)}{2x}, P_3(x) = -\frac{5}{2x}\right]$

  - $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left(x \cdot P_2(x)\right)\Big|_{x=0} = \frac{5}{2}$

  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $\left(x^2 \cdot P_3(x)\right)\Big|_{x=0} = 0$

  - $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $2\left(\frac{d^2}{dx^2}y(x)\right)x + (-10x+5)\left(\frac{d}{dx}y(x)\right) - 5y(x) = 0$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

- ☐ Rewrite ODE with series expansions
  - Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m = 0..1$

    $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1+m}$

  - Shift index using $k- >k+1-m$

    $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$

  - Convert $x \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

    $x \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, x^{k+r-1}$

  - Shift index using $k- >k+1$

    $x \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)(k+r)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0 r(3+2r)\, x^{-1+r} + \left(\sum_{k=0}^{\infty} \left(a_{k+1}(k+1+r)(2k+5+2r) - 5a_k(2k+2r+1)\right) x^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r(3+2r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \left\{0, -\frac{3}{2}\right\}$

- Each term in the series must be 0, giving the recursion relation
  $2(k+1+r)\left(k+r+\frac{5}{2}\right)a_{k+1}-10a_k\left(k+r+\frac{1}{2}\right)=0$
- Recursion relation that defines series solution to ODE
  $a_{k+1}=\frac{5a_k(2k+2r+1)}{(k+1+r)(2k+5+2r)}$
- Recursion relation for $r=0$
  $a_{k+1}=\frac{5a_k(2k+1)}{(k+1)(2k+5)}$
- Solution for $r=0$
  $\left[y(x)=\sum_{k=0}^{\infty}a_k x^k, a_{k+1}=\frac{5a_k(2k+1)}{(k+1)(2k+5)}\right]$
- Recursion relation for $r=-\frac{3}{2}$; series terminates at $k=1$
  $a_{k+1}=\frac{5a_k(2k-2)}{\left(k-\frac{1}{2}\right)(2k+2)}$
- Apply recursion relation for $k=0$
  $a_1=10a_0$
- Terminating series solution of the ODE for $r=-\frac{3}{2}$. Use reduction of order to find the second
  $y(x)=a_0\cdot(1+10x)$
- Combine solutions and rename parameters
  $\left[y(x)=\left(\sum_{k=0}^{\infty}a_k x^k\right)+b_0\cdot(1+10x), a_{k+1}=\frac{5a_k(2k+1)}{(k+1)(2k+5)}\right]$

2.1.255 Problem 258

Internal problem ID [9427]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 258
Date solved : `Monday, January 27, 2025 at 06:02:42 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' + xy' + \left(x^2 - \frac{1}{4}\right) y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.145 (sec)

Writing the ode as

$$x^2y'' + xy' + \left(x^2 - \frac{1}{4}\right) y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= x \\ C &= x^2 - \frac{1}{4} \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$s = -1$$
$$t = 1$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.487: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{x}{x^2}\, dx} \\ &= z_1 e^{-\frac{\ln(x)}{2}} \\ &= z_1 \left(\frac{1}{\sqrt{x}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{\cos(x)}{\sqrt{x}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{x}{x^2}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-\ln(x)}}{(y_1)^2}\, dx \\ &= y_1(\tan(x)) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\frac{\cos(x)}{\sqrt{x}}\right) + c_2 \left(\frac{\cos(x)}{\sqrt{x}}(\tan(x))\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve
$x^2\left(\frac{d^2}{dx^2}y(x)\right) + x\left(\frac{d}{dx}y(x)\right) + \left(x^2 - \frac{1}{4}\right)y(x) = 0$

- Highest derivative means the order of the ODE is 2
$\frac{d^2}{dx^2}y(x)$
- Isolate 2nd derivative
$\frac{d^2}{dx^2}y(x) = -\frac{(4x^2-1)y(x)}{4x^2} - \frac{\frac{d}{dx}y(x)}{x}$
- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin
$\frac{d^2}{dx^2}y(x) + \frac{\frac{d}{dx}y(x)}{x} + \frac{(4x^2-1)y(x)}{4x^2} = 0$

☐ Check to see if $x_0 = 0$ is a regular singular point

2.1.256 Problem 259

Internal problem ID [9428]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 259
Date solved : `Monday, January 27, 2025 at 06:02:42 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$xy'' + (x+n)\,y' + (n+1)\,y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.419 (sec)

Writing the ode as

$$xy'' + (x+n)\,y' + (n+1)\,y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x \\ B &= x+n \\ C &= n+1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{n^2 - 2xn + x^2 - 2n - 4x}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= n^2 - 2xn + x^2 - 2n - 4x \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{n^2 - 2xn + x^2 - 2n - 4x}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.489: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} + \frac{\frac{1}{4}n^2 - \frac{1}{2}n}{x^2} + \frac{-\frac{n}{2} - 1}{x}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{1}{4}n^2 - \frac{1}{2}n$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{n}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = 1 - \frac{n}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\
&= \sum_{i=0}^{0} a_i x^i \qquad (8)
\end{aligned}
$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$
\sqrt{r} \approx \frac{1}{2} - \frac{1}{x} - \frac{3n^5}{2x^6} - \frac{3n^4}{2x^5} - \frac{3n^3}{2x^4} - \frac{3n^2}{2x^3} - \frac{3n}{2x^2} - \frac{77n^5}{2x^7} - \frac{53n^4}{2x^6} - \frac{67n^3}{4x^5} - \frac{37n^2}{4x^4} - \frac{4n}{x^3} - \frac{1075n^4}{4x^7} - \frac{491n^3}{4x^6} - \frac{93n^2}{2x^5} - \frac{13n}{x^4} - 7 \qquad (9)
$$

Comparing Eq. (9) with Eq. (8) shows that

$$
a = \frac{1}{2}
$$

From Eq. (9) the sum up to $v = 0$ gives

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\
&= \frac{1}{2} \qquad (10)
\end{aligned}
$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$
\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}
$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$
r = Q + \frac{R}{t}
$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{n^2 - 2xn + x^2 - 2n - 4x}{4x^2} \\
&= Q + \frac{R}{4x^2} \\
&= \left(\frac{1}{4}\right) + \left(\frac{(-2n-4)\,x + n^2 - 2n}{4x^2}\right) \\
&= \frac{1}{4} + \frac{(-2n-4)\,x + n^2 - 2n}{4x^2}
\end{aligned}
$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is $-2n - 4$. Dividing this by leading coefficient in t which is 4 gives $-\frac{n}{2} - 1$. Now b can be found.

$$
\begin{aligned}
b &= \left(-\frac{n}{2} - 1\right) - (0) \\
&= -\frac{n}{2} - 1
\end{aligned}
$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \frac{1}{2} \\
\alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{n}{2}-1}{\frac{1}{2}} - 0\right) &&= -\frac{n}{2} - 1 \\
\alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{n}{2}-1}{\frac{1}{2}} - 0\right) &&= \frac{n}{2} + 1
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{n^2 - 2xn + x^2 - 2n - 4x}{4x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{n}{2}$	$1 - \frac{n}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
0	$\frac{1}{2}$	$-\frac{n}{2} - 1$	$\frac{n}{2} + 1$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = \frac{n}{2} + 1$ then

$$
\begin{aligned}
d &= \alpha_\infty^{-} - \left(\alpha_{c_1}^{+}\right) \\
&= \frac{n}{2} + 1 - \left(\frac{n}{2}\right) \\
&= 1
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x - c_1} \right) + (-)[\sqrt{r}]_\infty \\
&= \frac{n}{2x} + (-)\left(\frac{1}{2}\right) \\
&= \frac{n}{2x} - \frac{1}{2} \\
&= \frac{n - x}{2x}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = x + a_0 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(\frac{n}{2x}-\frac{1}{2}\right)(1)+\left(\left(-\frac{n}{2x^2}\right)+\left(\frac{n}{2x}-\frac{1}{2}\right)^2-\left(\frac{n^2-2xn+x^2-2n-4x}{4x^2}\right)\right)=0$$

$$\frac{n+a_0}{x}=0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0=-n\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x)=x-n$$

Therefore the first solution to the ode $z''=rz$ is

$$\begin{aligned}
z_1(x) &= pe^{\int \omega\, dx} \\
&= (x-n)\,\mathrm{e}^{\int \left(\frac{n}{2x}-\frac{1}{2}\right)dx} \\
&= (x-n)\,\mathrm{e}^{-\frac{x}{2}+\frac{n\ln(x)}{2}} \\
&= -(n-x)\,x^{\frac{n}{2}}\mathrm{e}^{-\frac{x}{2}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{x+n}{x}\, dx} \\
&= z_1 e^{-\frac{x}{2}-\frac{n\ln(x)}{2}} \\
&= z_1\left(x^{-\frac{n}{2}}\mathrm{e}^{-\frac{x}{2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1=(x-n)\,\mathrm{e}^{-x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2=y_1\int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1\int \frac{e^{\int -\frac{x+n}{x}\, dx}}{(y_1)^2}\, dx \\
&= y_1\int \frac{\mathrm{e}^{-n\ln(x)-x}}{(y_1)^2}\, dx \\
&= y_1\left(\int \frac{\mathrm{e}^{-n\ln(x)-x}\mathrm{e}^{2x}}{(x-n)^2}dx\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1y_1+c_2y_2 \\
&= c_1\left((x-n)\,\mathrm{e}^{-x}\right)+c_2\left((x-n)\,\mathrm{e}^{-x}\left(\int \frac{\mathrm{e}^{-n\ln(x)-x}\mathrm{e}^{2x}}{(x-n)^2}dx\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$\left(\frac{d^2}{dx^2}y(x)\right)x+(x+n)\left(\frac{d}{dx}y(x)\right)+(n+1)\,y(x)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x)=-\frac{(n+1)y(x)}{x}-\frac{(x+n)\left(\frac{d}{dx}y(x)\right)}{x}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x)+\frac{(x+n)\left(\frac{d}{dx}y(x)\right)}{x}+\frac{(n+1)y(x)}{x}=0$

□ Check to see if $x_0=0$ is a regular singular point

  - Define functions

    $\left[P_2(x)=\frac{x+n}{x},P_3(x)=\frac{n+1}{x}\right]$

  - $x\cdot P_2(x)$ is analytic at $x=0$

    $(x\cdot P_2(x))\Big|_{x=0}=n$

  - $x^2\cdot P_3(x)$ is analytic at $x=0$

    $(x^2\cdot P_3(x))\Big|_{x=0}=0$

  - $x=0$is a regular singular point

  Check to see if $x_0=0$ is a regular singular point

  $x_0=0$

- Multiply by denominators

  $\left(\frac{d^2}{dx^2}y(x)\right)x+(x+n)\left(\frac{d}{dx}y(x)\right)+(n+1)\,y(x)=0$

- Assume series solution for $y(x)$

  $y(x)=\sum_{k=0}^{\infty}a_kx^{k+r}$

□ Rewrite ODE with series expansions

  - Convert $x^m\cdot\left(\frac{d}{dx}y(x)\right)$ to series expansion for $m=0..1$

    $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,x^{k+r-1+m}$

  - Shift index using $k->k+1-m$

    $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,x^{k+r}$

  - Convert $x\cdot\left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

    $x\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,x^{k+r-1}$

  - Shift index using $k->k+1$

    $x\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=-1}^{\infty}a_{k+1}(k+1+r)\,(k+r)\,x^{k+r}$

  Rewrite ODE with series expansions

  $a_0r(-1+r+n)\,x^{-1+r}+\left(\sum_{k=0}^{\infty}\left(a_{k+1}(k+1+r)\,(k+r+n)+a_k(n+k+r+1)\right)x^{k+r}\right)=0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r(-1+r+n)=0$

- Values of r that satisfy the indicial equation

  $r\in\{0,1-n\}$

- Each term in the series must be 0, giving the recursion relation
  $a_{k+1}(k+1+r)(k+r+n)+a_k(n+k+r+1)=0$
- Recursion relation that defines series solution to ODE
  $a_{k+1}=-\frac{a_k(n+k+r+1)}{(k+1+r)(k+r+n)}$
- Recursion relation for $r=0$
  $a_{k+1}=-\frac{a_k(n+k+1)}{(k+1)(k+n)}$
- Solution for $r=0$
  $\left[y(x)=\sum_{k=0}^{\infty} a_k x^k, a_{k+1}=-\frac{a_k(n+k+1)}{(k+1)(k+n)}\right]$
- Recursion relation for $r=1-n$
  $a_{k+1}=-\frac{a_k(k+2)}{(k+2-n)(k+1)}$
- Solution for $r=1-n$
  $\left[y(x)=\sum_{k=0}^{\infty} a_k x^{k+1-n}, a_{k+1}=-\frac{a_k(k+2)}{(k+2-n)(k+1)}\right]$
- Combine solutions and rename parameters
  $\left[y(x)=\left(\sum_{k=0}^{\infty} a_k x^k\right)+\left(\sum_{k=0}^{\infty} b_k x^{k+1-n}\right), a_{k+1}=-\frac{a_k(n+k+1)}{(k+1)(k+n)}, b_{k+1}=-\frac{b_k(k+2)}{(k+2-n)(k+1)}\right]$

2.1.257 Problem 260

Internal problem ID [9429]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 260
Date solved : `Monday, January 27, 2025 at 06:02:43 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^4y'' + xy' + y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.336 (sec)

Writing the ode as

$$x^4y'' + xy' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^4 \\ B &= x \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A} \,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-10x^2 + 1}{4x^6} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -10x^2 + 1 \\ t &= 4x^6 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{-10x^2 + 1}{4x^6}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.491: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 2 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^6$. There is a pole at $x = 0$ of order 6. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Looking at higher order poles of order $2v \geq 4$ (must be even order for case one).Then for each pole c, $[\sqrt{r}]_c$ is the sum of terms $\frac{1}{(x-c)^i}$ for $2 \leq i \leq v$ in the Laurent series expansion of $\sqrt{r}$ expanded around each pole c. Hence

$$[\sqrt{r}]_c = \sum_{2}^{v} \frac{a_i}{(x-c)^i} \tag{1B}$$

Let a be the coefficient of the term $\frac{1}{(x-c)^v}$ in the above where v is the pole order divided by 2. Let b be the coefficient of $\frac{1}{(x-c)^{v+1}}$ in r minus the coefficient of $\frac{1}{(x-c)^{v+1}}$ in $[\sqrt{r}]_c$. Then

$$\begin{aligned} \alpha_c^+ &= \frac{1}{2}\left(\frac{b}{a} + v\right) \\ \alpha_c^- &= \frac{1}{2}\left(-\frac{b}{a} + v\right) \end{aligned}$$

The partial fraction decomposition of r is

$$r = -\frac{5}{2x^4} + \frac{1}{4x^6}$$

There is pole in r at $x = 0$ of order 6, hence $v = 3$. Expanding $\sqrt{r}$ as Laurent series about this pole $c = 0$ gives

$$[\sqrt{r}]_c \approx \frac{1}{2x^3} - \frac{5}{2x} - \frac{25x}{4} + \dots \tag{2B}$$

Using eq. (1B), taking the sum up to $v = 3$ the above becomes

$$[\sqrt{r}]_c = \frac{1}{2x^3} \tag{3B}$$

The above shows that the coefficient of $\frac{1}{(x-0)^3}$ is

$$a = \frac{1}{2}$$

Now we need to find b. let b be the coefficient of the term $\frac{1}{(x-c)^{v+1}}$ in r minus the coefficient of the same term but in the sum $[\sqrt{r}]_c$ found in eq. (3B). Here c is current pole which is $c = 0$. This term becomes $\frac{1}{x^4}$. The coefficient of this term in the sum $[\sqrt{r}]_c$ is seen to be 0 and the coefficient of this term r is found from the partial fraction decomposition from above to be $-\frac{5}{2}$. Therefore

$$\begin{aligned} b &= \left(-\frac{5}{2}\right) - (0) \\ &= -\frac{5}{2} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_c &= \frac{1}{2x^3} \\ \alpha_c^+ &= \frac{1}{2}\left(\frac{b}{a} + v\right) &&= \frac{1}{2}\left(\frac{-\frac{5}{2}}{\frac{1}{2}} + 3\right) &&= -1 \\ \alpha_c^- &= \frac{1}{2}\left(-\frac{b}{a} + v\right) &&= \frac{1}{2}\left(-\frac{-\frac{5}{2}}{\frac{1}{2}} + 3\right) &&= 4 \end{aligned}$$

Since the order of r at ∞ is $4 > 2$ then

$$\begin{aligned} [\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^+ &= 0 \\ \alpha_\infty^- &= 1 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{-10x^2 + 1}{4x^6}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	6	$\frac{1}{2x^3}$	-1	4

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$ then

$$\begin{aligned} d &= \alpha_\infty^- - (\alpha_{c_1}^+) \\ &= 1 - (-1) \\ &= 2 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x - c_1} \right) + (-)[\sqrt{r}]_\infty \\
&= \frac{1}{2x^3} - \frac{1}{x} + (-)\,(0) \\
&= \frac{1}{2x^3} - \frac{1}{x} \\
&= \frac{1}{2x^3} - \frac{1}{x}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 2$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x^2 + a_1 x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(2) + 2\left(\frac{1}{2x^3} - \frac{1}{x}\right)(2x + a_1) + \left(\left(-\frac{3}{2x^4} + \frac{1}{x^2}\right) + \left(\frac{1}{2x^3} - \frac{1}{x}\right)^2 - \left(\frac{-10x^2 + 1}{4x^6}\right)\right) = 0$$

$$\frac{(2a_0 + 2)\,x + a_1}{x^3} = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = -1, a_1 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^2 - 1$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx} \\
&= \left(x^2 - 1\right) e^{\int \left(\frac{1}{2x^3} - \frac{1}{x}\right) dx} \\
&= \left(x^2 - 1\right) e^{-\ln(x) - \frac{1}{4x^2}} \\
&= \frac{\left(x^2 - 1\right) e^{-\frac{1}{4x^2}}}{x}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{x}{x^4}\, dx} \\
&= z_1 e^{\frac{1}{4x^2}} \\
&= z_1 \left(e^{\frac{1}{4x^2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{x^2 - 1}{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{x}{x^4}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{\frac{1}{2x^2}}}{(y_1)^2}\, dx \\ &= y_1 \left(\int \frac{e^{\frac{1}{2x^2}} x^2}{(x^2-1)^2} dx\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\frac{x^2-1}{x}\right) + c_2 \left(\frac{x^2-1}{x}\left(\int \frac{e^{\frac{1}{2x^2}} x^2}{(x^2-1)^2} dx\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

2.1.258 Problem 261

Internal problem ID [9430]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 261
Date solved : `Monday, January 27, 2025 at 06:02:44 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' + (2x^2 + x)\, y' - 4y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.248 (sec)

Writing the ode as

$$x^2y'' + (2x^2 + x)\, y' - 4y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= 2x^2 + x \\ C &= -4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{4x^2 + 4x + 15}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 4x^2 + 4x + 15 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{4x^2 + 4x + 15}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.492: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = 1 + \frac{15}{4x^2} + \frac{1}{x}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{15}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{5}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{3}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx 1 + \frac{1}{2x} + \frac{7}{4x^2} - \frac{7}{8x^3} - \frac{35}{32x^4} + \frac{133}{64x^5} + \frac{63}{128x^6} - \frac{1239}{256x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = 1$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= 1 \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = 1$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{4x^2 + 4x + 15}{4x^2} \\ &= Q + \frac{R}{4x^2} \\ &= (1) + \left(\frac{4x + 15}{4x^2}\right) \\ &= 1 + \frac{4x + 15}{4x^2} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is 4. Dividing this by leading coefficient in t which is 4 gives 1. Now b can be found.

$$\begin{aligned} b &= (1) - (0) \\ &= 1 \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= 1 \\ \alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{1}{1} - 0\right) &= \frac{1}{2} \\ \alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{1}{1} - 0\right) &= -\frac{1}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{4x^2 + 4x + 15}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{5}{2}$	$-\frac{3}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	1	$\frac{1}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -\frac{1}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^- - (\alpha_{c_1}^-) \\
&= -\frac{1}{2} - \left(-\frac{3}{2}\right) \\
&= 1
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{3}{2x} + (-)(1) \\
&= -\frac{3}{2x} - 1 \\
&= -\frac{3}{2x} - 1
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned}
(0) + 2\left(-\frac{3}{2x} - 1\right)(1) + \left(\left(\frac{3}{2x^2}\right) + \left(-\frac{3}{2x} - 1\right)^2 - \left(\frac{4x^2 + 4x + 15}{4x^2}\right) \right) &= 0 \\
\frac{-3 + 2a_0}{x} &= 0
\end{aligned}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\left\{ a_0 = \frac{3}{2} \right\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x + \frac{3}{2}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= \left(x + \frac{3}{2}\right) e^{\int \left(-\frac{3}{2x} - 1\right) dx} \\ &= \left(x + \frac{3}{2}\right) e^{-x - \frac{3\ln(x)}{2}} \\ &= \frac{(3 + 2x)\, e^{-x}}{2x^{3/2}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{2x^2 + x}{x^2}\, dx} \\ &= z_1 e^{-x - \frac{\ln(x)}{2}} \\ &= z_1 \left(\frac{e^{-x}}{\sqrt{x}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{e^{-2x}(3 + 2x)}{2x^2}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{2x^2 + x}{x^2}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-2x - \ln(x)}}{(y_1)^2}\, dx \\ &= y_1 \left(\frac{(2x^2 - 4x + 3)\, x\, e^{-2x - \ln(x)} e^{4x}}{6 + 4x}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\frac{e^{-2x}(3 + 2x)}{2x^2}\right) + c_2 \left(\frac{e^{-2x}(3 + 2x)}{2x^2} \left(\frac{(2x^2 - 4x + 3)\, x\, e^{-2x - \ln(x)} e^{4x}}{6 + 4x}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2\left(\frac{d^2}{dx^2}y(x)\right)+(2x^2+x)\left(\frac{d}{dx}y(x)\right)-4y(x)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x)=\frac{4y(x)}{x^2}-\frac{(2x+1)\left(\frac{d}{dx}y(x)\right)}{x}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x)+\frac{(2x+1)\left(\frac{d}{dx}y(x)\right)}{x}-\frac{4y(x)}{x^2}=0$

- □ Check to see if $x_0=0$ is a regular singular point
  - ∘ Define functions

    $\left[P_2(x)=\frac{2x+1}{x},P_3(x)=-\frac{4}{x^2}\right]$

  - ∘ $x\cdot P_2(x)$ is analytic at $x=0$

    $(x\cdot P_2(x))\Big|_{x=0}=1$

  - ∘ $x^2\cdot P_3(x)$ is analytic at $x=0$

    $(x^2\cdot P_3(x))\Big|_{x=0}=-4$

  - ∘ $x=0$is a regular singular point

    Check to see if $x_0=0$ is a regular singular point

    $x_0=0$

- Multiply by denominators

  $x^2\left(\frac{d^2}{dx^2}y(x)\right)+x(2x+1)\left(\frac{d}{dx}y(x)\right)-4y(x)=0$

- Assume series solution for $y(x)$

  $y(x)=\sum_{k=0}^{\infty}a_kx^{k+r}$

- □ Rewrite ODE with series expansions
  - ∘ Convert $x^m\cdot\left(\frac{d}{dx}y(x)\right)$ to series expansion for $m=1..2$

    $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,x^{k+r-1+m}$

  - ∘ Shift index using $k->k+1-m$

    $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,x^{k+r}$

  - ∘ Convert $x^2\cdot\left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

    $x^2\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,x^{k+r}$

    Rewrite ODE with series expansions

    $a_0(2+r)\,(-2+r)\,x^r+\left(\sum_{k=1}^{\infty}\left(a_k(k+r+2)\,(k+r-2)+2a_{k-1}(k+r-1)\right)x^{k+r}\right)=0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(2+r)\,(-2+r)=0$

- Values of r that satisfy the indicial equation

  $r\in\{-2,2\}$

- Each term in the series must be 0, giving the recursion relation

  $a_k(k+r+2)\,(k+r-2)+2a_{k-1}(k+r-1)=0$

- Shift index using $k->k+1$

$a_{k+1}(k+3+r)(k+r-1)+2a_k(k+r)=0$

- Recursion relation that defines series solution to ODE

  $a_{k+1}=-\frac{2a_k(k+r)}{(k+3+r)(k+r-1)}$
- Recursion relation for $r=-2$; series terminates at $k=2$

  $a_{k+1}=-\frac{2a_k(k-2)}{(k+1)(k-3)}$
- Apply recursion relation for $k=0$

  $a_1=-\frac{4a_0}{3}$
- Apply recursion relation for $k=1$

  $a_2=-\frac{a_1}{2}$
- Express in terms of a_0

  $a_2=\frac{2a_0}{3}$
- Terminating series solution of the ODE for $r=-2$. Use reduction of order to find the second lin

  $y(x)=a_0\cdot\left(1-\frac{4}{3}x+\frac{2}{3}x^2\right)$
- Recursion relation for $r=2$

  $a_{k+1}=-\frac{2a_k(k+2)}{(k+5)(k+1)}$
- Solution for $r=2$

  $\left[y(x)=\sum_{k=0}^{\infty}a_kx^{k+2}, a_{k+1}=-\frac{2a_k(k+2)}{(k+5)(k+1)}\right]$
- Combine solutions and rename parameters

  $\left[y(x)=a_0\cdot\left(1-\frac{4}{3}x+\frac{2}{3}x^2\right)+\left(\sum_{k=0}^{\infty}b_kx^{k+2}\right), b_{k+1}=-\frac{2b_k(k+2)}{(5+k)(k+1)}\right]$

2.1.259 Problem 262

Internal problem ID [9431]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 262
Date solved : `Monday, January 27, 2025 at 06:02:45 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$\left(4x^3-14x^2-2x\right)y''-\left(6x^2-7x+1\right)y'+\left(6x-1\right)y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.446 (sec)

Writing the ode as

$$\left(4x^3-14x^2-2x\right)y''+\left(-6x^2+7x-1\right)y'+\left(6x-1\right)y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A&=4x^3-14x^2-2x\\ B&=-6x^2+7x-1\\ C&=6x-1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r&=\frac{s}{t}\\ &=\frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{-12x^4+156x^3+297x^2-78x-3}{16\left(2x^3-7x^2-x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s&=-12x^4+156x^3+297x^2-78x-3\\ t&=16\left(2x^3-7x^2-x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{-12x^4+156x^3+297x^2-78x-3}{16\left(2x^3-7x^2-x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.494: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 4 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16(2x^3 - 7x^2 - x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = \frac{7}{4} + \frac{\sqrt{57}}{4}$ of order 2. There is a pole at $x = \frac{7}{4} - \frac{\sqrt{57}}{4}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{3}{4\left(x - \frac{7}{4} - \frac{\sqrt{57}}{4}\right)^2} + \frac{3}{4\left(x - \frac{7}{4} + \frac{\sqrt{57}}{4}\right)^2} + \frac{\frac{9}{8} - \frac{29\sqrt{57}}{152}}{x - \frac{7}{4} - \frac{\sqrt{57}}{4}} + \frac{\frac{9}{8} + \frac{29\sqrt{57}}{152}}{x - \frac{7}{4} + \frac{\sqrt{57}}{4}} - \frac{9}{4x} - \frac{3}{16x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{4} \end{aligned}$$

For the pole at $x = \frac{7}{4}+\frac{\sqrt{57}}{4}$ let b be the coefficient of $\frac{1}{\left(x-\frac{7}{4}-\frac{\sqrt{57}}{4}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^{+} &= \frac{1}{2}+\sqrt{1+4b} = \frac{3}{2}\\ \alpha_c^{-} &= \frac{1}{2}-\sqrt{1+4b} = -\frac{1}{2}\end{aligned}$$

For the pole at $x = \frac{7}{4}-\frac{\sqrt{57}}{4}$ let b be the coefficient of $\frac{1}{\left(x-\frac{7}{4}+\frac{\sqrt{57}}{4}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^{+} &= \frac{1}{2}+\sqrt{1+4b} = \frac{3}{2}\\ \alpha_c^{-} &= \frac{1}{2}-\sqrt{1+4b} = -\frac{1}{2}\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{-12x^4+156x^3+297x^2-78x-3}{16\left(2x^3-7x^2-x\right)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{3}{16}$. Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= 0\\ \alpha_\infty^{+} &= \frac{1}{2}+\sqrt{1+4b} = \frac{3}{4}\\ \alpha_\infty^{-} &= \frac{1}{2}-\sqrt{1+4b} = \frac{1}{4}\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{-12x^4+156x^3+297x^2-78x-3}{16\left(2x^3-7x^2-x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{3}{4}$	$\frac{1}{4}$
$\frac{7}{4}+\frac{\sqrt{57}}{4}$	2	0	$\frac{3}{2}$	$-\frac{1}{2}$
$\frac{7}{4}-\frac{\sqrt{57}}{4}$	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{3}{4}$	$\frac{1}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = \frac{1}{4}$ then

$$\begin{aligned}d &= \alpha_\infty^{-} - \left(\alpha_{c_1}^{-}+\alpha_{c_2}^{-}+\alpha_{c_3}^{-}\right)\\ &= \frac{1}{4} - \left(-\frac{3}{4}\right)\\ &= 1\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2} \right) + \left((-)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^-}{x-c_3} \right) + (-)[\sqrt{r}]_\infty \\
&= \frac{1}{4x} - \frac{1}{2\left(x-\frac{7}{4}-\frac{\sqrt{57}}{4}\right)} - \frac{1}{2\left(x-\frac{7}{4}+\frac{\sqrt{57}}{4}\right)} + (-)(0) \\
&= \frac{1}{4x} - \frac{1}{2\left(x-\frac{7}{4}-\frac{\sqrt{57}}{4}\right)} - \frac{1}{2\left(x-\frac{7}{4}+\frac{\sqrt{57}}{4}\right)} \\
&= \frac{-6x^2+7x-1}{8x^3-28x^2-4x}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{4x} - \frac{1}{2\left(x-\frac{7}{4}-\frac{\sqrt{57}}{4}\right)} - \frac{1}{2\left(x-\frac{7}{4}+\frac{\sqrt{57}}{4}\right)} \right)(1) + \left(\left(-\frac{1}{4x^2} + \frac{1}{2\left(x-\frac{7}{4}-\frac{\sqrt{57}}{4}\right)^2} + \frac{1}{2\left(x-\frac{7}{4}+\right.}\right.\right.$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = -1\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x - 1$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= pe^{\int \omega\, dx} \\
&= (x-1)\,\mathrm{e}^{\int \left(\frac{1}{4x} - \frac{1}{2\left(x-\frac{7}{4}-\frac{\sqrt{57}}{4}\right)} - \frac{1}{2\left(x-\frac{7}{4}+\frac{\sqrt{57}}{4}\right)} \right) dx} \\
&= (x-1)\,\mathrm{e}^{\frac{\left(-57+7\sqrt{57}\right)\sqrt{57}\,\ln\left(4x-7+\sqrt{57}\right)}{-798+114\sqrt{57}} + \frac{2\ln(x)}{\left(7+\sqrt{57}\right)\left(-7+\sqrt{57}\right)} - \frac{\left(57+7\sqrt{57}\right)\sqrt{57}\,\ln\left(4x-7-\sqrt{57}\right)}{2\left(399+57\sqrt{57}\right)}} \\
&= \frac{(x-1)\,x^{1/4}}{\sqrt{4x-7+\sqrt{57}}\,\sqrt{4x-7-\sqrt{57}}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-6x^2+7x-1}{4x^3-14x^2-2x}\, dx} \\
&= z_1 e^{-\frac{\ln(x)}{4} + \frac{\ln\left(2x^2-7x-1\right)}{2}} \\
&= z_1 \left(\frac{\sqrt{2x^2-7x-1}}{x^{1/4}} \right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{(x-1)\sqrt{2}}{4}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-6x^2+7x-1}{4x^3-14x^2-2x}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-\frac{\ln(x)}{2}+\ln(2x^2-7x-1)}}{(y_1)^2}\, dx \\ &= y_1 \left(\frac{16x(2x+1)\,\mathrm{e}^{-\frac{\ln(x)}{2}+\ln(2x^2-7x-1)}}{(x-1)(2x^2-7x-1)}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\frac{(x-1)\sqrt{2}}{4}\right) + c_2\left(\frac{(x-1)\sqrt{2}}{4}\left(\frac{16x(2x+1)\,\mathrm{e}^{-\frac{\ln(x)}{2}+\ln(2x^2-7x-1)}}{(x-1)(2x^2-7x-1)}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' + x^2y' + (x-2)\, y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.204 (sec)

Writing the ode as

$$x^2y'' + x^2y' + (x-2)\, y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= x^2 \\ C &= x-2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 - 4x + 8}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2 - 4x + 8 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2 - 4x + 8}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.496: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} + \frac{2}{x^2} - \frac{1}{x}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -1 \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} - \frac{1}{x} + \frac{1}{x^2} + \frac{2}{x^3} + \frac{3}{x^4} + \frac{2}{x^5} - \frac{6}{x^6} - \frac{28}{x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{2}\end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned}r &= \frac{s}{t} \\ &= \frac{x^2 - 4x + 8}{4x^2} \\ &= Q + \frac{R}{4x^2} \\ &= \left(\frac{1}{4}\right) + \left(\frac{-4x + 8}{4x^2}\right) \\ &= \frac{1}{4} + \frac{-4x + 8}{4x^2}\end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is -4. Dividing this by leading coefficient in t which is 4 gives -1. Now b can be found.

$$\begin{aligned}b &= (-1) - (0) \\ &= -1\end{aligned}$$

Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= \frac{1}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-1}{\frac{1}{2}} - 0\right) &= -1 \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-1}{\frac{1}{2}} - 0\right) &= 1\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2 - 4x + 8}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	2	-1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	-1	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = -1$ then

$$\begin{aligned} d &= \alpha_\infty^+ - \left(\alpha_{c_1}^-\right) \\ &= -1 - (-1) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (+)[\sqrt{r}]_\infty \\ &= -\frac{1}{x} + \left(\frac{1}{2}\right) \\ &= \frac{1}{2} - \frac{1}{x} \\ &= \frac{x-2}{2x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(\frac{1}{2} - \frac{1}{x}\right)(0) + \left(\left(\frac{1}{x^2}\right) + \left(\frac{1}{2} - \frac{1}{x}\right)^2 - \left(\frac{x^2-4x+8}{4x^2}\right) \right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= \mathrm{e}^{\int \left(\frac{1}{2} - \frac{1}{x}\right) dx} \\ &= \frac{\mathrm{e}^{\frac{x}{2}}}{x} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{x^2}{x^2}\,dx} \\ &= z_1 e^{-\frac{x}{2}} \\ &= z_1 \left(\mathrm{e}^{-\frac{x}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{1}{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{x^2}{x^2}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{-x}}{(y_1)^2}\,dx \\ &= y_1\left(-\left(x^2+2x+2\right)\mathrm{e}^{-x}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\frac{1}{x}\right) + c_2\left(\frac{1}{x}\left(-\left(x^2+2x+2\right)\mathrm{e}^{-x}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

  $x^2 \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r+1}$
- Shift index using $k- > k - 1$
  $x^2 \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=1}^{\infty} a_{k-1}(k-1+r)\, x^{k+r}$
- Convert $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion
  $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k-1+r)\, x^{k+r}$

  Rewrite ODE with series expansions
  $a_0(1+r)\,(-2+r)\, x^r + \left(\sum_{k=1}^{\infty} \left(a_k(k+r+1)\,(k+r-2) + a_{k-1}(k+r)\right) x^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $(1+r)\,(-2+r) = 0$
- Values of r that satisfy the indicial equation
  $r \in \{-1, 2\}$
- Each term in the series must be 0, giving the recursion relation
  $a_k(k+r+1)\,(k+r-2) + a_{k-1}(k+r) = 0$
- Shift index using $k- > k + 1$
  $a_{k+1}(k+2+r)\,(k-1+r) + a_k(k+r+1) = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+1} = -\frac{a_k(k+r+1)}{(k+2+r)(k-1+r)}$
- Recursion relation for $r = -1$
  $a_{k+1} = -\frac{a_k k}{(k+1)(k-2)}$
- Series not valid for $r = -1$, division by 0 in the recursion relation at $k = 2$
  $a_{k+1} = -\frac{a_k k}{(k+1)(k-2)}$
- Recursion relation for $r = 2$
  $a_{k+1} = -\frac{a_k(k+3)}{(k+4)(k+1)}$
- Solution for $r = 2$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+2}, a_{k+1} = -\frac{a_k(k+3)}{(k+4)(k+1)}\right]$

2.1.261 Problem 264

Internal problem ID [9433]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 264
Date solved : `Monday, January 27, 2025 at 06:02:46 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' - x^2y' + (x-2)\,y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.204 (sec)

Writing the ode as

$$x^2y'' - x^2y' + (x-2)\,y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -x^2 \\ C &= x-2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 - 4x + 8}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2 - 4x + 8 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2 - 4x + 8}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.498: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 2 - 2 \\
&= 0
\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} + \frac{2}{x^2} - \frac{1}{x}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1
\end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\
&= \sum_{i=0}^{0} a_i x^i
\end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} - \frac{1}{x} + \frac{1}{x^2} + \frac{2}{x^3} + \frac{3}{x^4} + \frac{2}{x^5} - \frac{6}{x^6} - \frac{28}{x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{2}\end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned}r &= \frac{s}{t} \\ &= \frac{x^2 - 4x + 8}{4x^2} \\ &= Q + \frac{R}{4x^2} \\ &= \left(\frac{1}{4}\right) + \left(\frac{-4x + 8}{4x^2}\right) \\ &= \frac{1}{4} + \frac{-4x + 8}{4x^2}\end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is -4. Dividing this by leading coefficient in t which is 4 gives -1. Now b can be found.

$$\begin{aligned}b &= (-1) - (0) \\ &= -1\end{aligned}$$

Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= \frac{1}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-1}{\frac{1}{2}} - 0\right) &= -1 \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-1}{\frac{1}{2}} - 0\right) &= 1\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2 - 4x + 8}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	2	-1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	-1	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = -1$ then

$$\begin{aligned} d &= \alpha_\infty^+ - (\alpha_{c_1}^-) \\ &= -1 - (-1) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (+)[\sqrt{r}]_\infty \\ &= -\frac{1}{x} + \left(\frac{1}{2}\right) \\ &= \frac{1}{2} - \frac{1}{x} \\ &= \frac{x-2}{2x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(\frac{1}{2} - \frac{1}{x}\right)(0) + \left(\left(\frac{1}{x^2}\right) + \left(\frac{1}{2} - \frac{1}{x}\right)^2 - \left(\frac{x^2-4x+8}{4x^2}\right) \right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega\, dx} \\ &= e^{\int \left(\frac{1}{2} - \frac{1}{x}\right) dx} \\ &= \frac{e^{\frac{x}{2}}}{x} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-x^2}{x^2}\,dx} \\ &= z_1 e^{\frac{x}{2}} \\ &= z_1 \left(\mathrm{e}^{\frac{x}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{\mathrm{e}^x}{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-x^2}{x^2}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^x}{(y_1)^2}\,dx \\ &= y_1\left(-\left(x^2+2x+2\right)\mathrm{e}^{-x}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\frac{\mathrm{e}^x}{x}\right) + c_2\left(\frac{\mathrm{e}^x}{x}\left(-\left(x^2+2x+2\right)\mathrm{e}^{-x}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2\left(\frac{d^2}{dx^2}y(x)\right) - x^2\left(\frac{d}{dx}y(x)\right) + (x-2)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{(x-2)y(x)}{x^2} + \frac{d}{dx}y(x)$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x) - \frac{d}{dx}y(x) + \frac{(x-2)y(x)}{x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

    $\left[P_2(x) = -1, P_3(x) = \frac{x-2}{x^2}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left.(x \cdot P_2(x))\right|_{x=0} = 0$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

$(x^2 \cdot P_3(x))\bigg|_{x=0} = -2$

- $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $x^2\left(\frac{d^2}{dx^2}y(x)\right) - x^2\left(\frac{d}{dx}y(x)\right) + (x-2)\, y(x) = 0$

- Assume series solution for $y(x)$

  $y(x) = \sum\limits_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

- Convert $x^m \cdot y(x)$ to series expansion for $m = 0..1$

  $x^m \cdot y(x) = \sum\limits_{k=0}^{\infty} a_k x^{k+r+m}$

- Shift index using $k- >k-m$

  $x^m \cdot y(x) = \sum\limits_{k=m}^{\infty} a_{k-m} x^{k+r}$

- Convert $x^2 \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion

  $x^2 \cdot \left(\frac{d}{dx}y(x)\right) = \sum\limits_{k=0}^{\infty} a_k(k+r)\, x^{k+r+1}$

- Shift index using $k- >k-1$

  $x^2 \cdot \left(\frac{d}{dx}y(x)\right) = \sum\limits_{k=1}^{\infty} a_{k-1}(k-1+r)\, x^{k+r}$

- Convert $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

  $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum\limits_{k=0}^{\infty} a_k(k+r)\,(k-1+r)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(1+r)\,(-2+r)\, x^r + \left(\sum\limits_{k=1}^{\infty} \left(a_k(k+r+1)\,(k+r-2) - a_{k-1}(k+r-2)\right) x^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(1+r)\,(-2+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{-1, 2\}$

- Each term in the series must be 0, giving the recursion relation

  $(k+r-2)\,(a_k(k+r+1) - a_{k-1}) = 0$

- Shift index using $k- >k+1$

  $(k-1+r)\,(a_{k+1}(k+2+r) - a_k) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+1} = \frac{a_k}{k+2+r}$

- Recursion relation for $r = -1$

  $a_{k+1} = \frac{a_k}{k+1}$

- Solution for $r = -1$

  $\left[y(x) = \sum\limits_{k=0}^{\infty} a_k x^{k-1}, a_{k+1} = \frac{a_k}{k+1}\right]$

- Recursion relation for $r = 2$

  $a_{k+1} = \frac{a_k}{k+4}$

- Solution for $r = 2$

  $\left[y(x) = \sum\limits_{k=0}^{\infty} a_k x^{k+2}, a_{k+1} = \frac{a_k}{k+4}\right]$

- Combine solutions and rename parameters

$$\left[y(x) = \left(\sum_{k=0}^{\infty} a_k x^{k-1}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+2}\right), a_{k+1} = \frac{a_k}{k+1}, b_{k+1} = \frac{b_k}{4+k}\right]$$

2.1.262 Problem 265

Internal problem ID [9434]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 265
Date solved : `Monday, January 27, 2025 at 06:02:47 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2(1-4x)\,y''-\frac{xy'}{2}-\frac{3xy}{4}=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.297 (sec)

Writing the ode as

$$\left(-4x^3+x^2\right)y''-\frac{xy'}{2}-\frac{3xy}{4}=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A&=-4x^3+x^2\\ B&=-\frac{x}{2}\\ C&=-\frac{3x}{4} \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r&=\frac{s}{t} \\ &=\frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{-48x^2-20x+5}{16\left(4x^2-x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s&=-48x^2-20x+5\\ t&=16\left(4x^2-x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{-48x^2 - 20x + 5}{16 (4x^2 - x)^2} \right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.500: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16(4x^2 - x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = \frac{1}{4}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Unable to find solution using case one

Attempting to find a solution using case $n = 2$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{5}{4x} + \frac{5}{16x^2} - \frac{3}{16 \left(x - \frac{1}{4}\right)^2} - \frac{5}{4 \left(x - \frac{1}{4}\right)}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{5}{16}$. Hence

$$\begin{aligned} E_c &= \{2, 2 + 2\sqrt{1 + 4b}, 2 - 2\sqrt{1 + 4b}\} \\ &= \{-1, 2, 5\} \end{aligned}$$

For the pole at $x = \frac{1}{4}$ let b be the coefficient of $\frac{1}{(x-\frac{1}{4})^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} E_c &= \{2, 2 + 2\sqrt{1+4b}, 2 - 2\sqrt{1+4b}\} \\ &= \{1, 2, 3\} \end{aligned}$$

Since the order of r at ∞ is 2 then let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{-48x^2 - 20x + 5}{16\,(4x^2 - x)^2}$$

Since the $\gcd(s, t) = 1$. This gives $b = -\frac{3}{16}$. Hence

$$\begin{aligned} E_\infty &= \{2, 2 + 2\sqrt{1+4b}, 2 - 2\sqrt{1+4b}\} \\ &= \{1, 2, 3\} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ for case 2 of Kovacic algorithm.

pole c location	pole order	E_c
0	2	$\{-1, 2, 5\}$
$\frac{1}{4}$	2	$\{1, 2, 3\}$

Order of r at ∞	E_∞
2	$\{1, 2, 3\}$

Using the family $\{e_1, e_2, \dots, e_\infty\}$ given by

$$e_1 = 2,\; e_2 = 1,\; e_\infty = 3$$

Gives a non negative integer d (the degree of the polynomial $p(x)$), which is generated using

$$\begin{aligned} d &= \frac{1}{2}\left(e_\infty - \sum_{c\in\Gamma} e_c\right) \\ &= \frac{1}{2}(3 - (2 + (1))) \\ &= 0 \end{aligned}$$

We now form the following rational function

$$\begin{aligned} \theta &= \frac{1}{2}\sum_{c\in\Gamma} \frac{e_c}{x - c} \\ &= \frac{1}{2}\left(\frac{2}{(x - (0))} + \frac{1}{(x - (\frac{1}{4}))}\right) \\ &= \frac{1}{x} + \frac{1}{2x - \frac{1}{2}} \end{aligned}$$

Now we search for a monic polynomial $p(x)$ of degree $d = 0$ such that

$$p''' + 3\theta p'' + (3\theta^2 + 3\theta' - 4r)\, p' + (\theta'' + 3\theta\theta' + \theta^3 - 4r\theta - 2r')\, p = 0 \tag{1A}$$

Since $d = 0$, then letting

$$p = 1 \tag{2A}$$

Substituting p and θ into Eq. (1A) gives

$$0 = 0$$

And solving for p gives

$$p = 1$$

Now that $p(x)$ is found let

$$\begin{aligned}\phi &= \theta + \frac{p'}{p}\\ &= \frac{1}{x} + \frac{1}{2x - \frac{1}{2}}\end{aligned}$$

Let ω be the solution of

$$\omega^2 - \phi\omega + \left(\frac{1}{2}\phi' + \frac{1}{2}\phi^2 - r\right) = 0$$

Substituting the values for ϕ and r into the above equation gives

$$w^2 - \left(\frac{1}{x} + \frac{1}{2x - \frac{1}{2}}\right) w + \frac{144x^2 - 12x - 5}{16x^2 (-1 + 4x)^2} = 0$$

Solving for ω gives

$$\omega = \frac{12x - 2 + 3\sqrt{1 - 4x}}{4x (-1 + 4x)}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}z_1(x) &= e^{\int \omega \, dx}\\ &= e^{\int \frac{12x - 2 + 3\sqrt{1-4x}}{4x(-1+4x)} dx}\\ &= \frac{(-1 + 4x)^{1/4} \sqrt{x}\,\sqrt{2} \left(\frac{\sqrt{1-4x}+1}{\sqrt{x}}\right)^{3/2}}{4}\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx}\\ &= z_1 e^{-\int \frac{1}{2} \frac{-\frac{x}{2}}{-4x^3+x^2} \, dx}\\ &= z_1 e^{-\frac{\ln(-1+4x)}{4} + \frac{\ln(x)}{4}}\\ &= z_1 \left(\frac{x^{1/4}}{(-1 + 4x)^{1/4}}\right)\end{aligned}$$

Which simplifies to

$$y_1 = \frac{x^{1/4}\sqrt{2}\left(\sqrt{1 - 4x} + 1\right)\sqrt{\frac{\sqrt{1-4x}+1}{\sqrt{x}}}}{4}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned}y_2 &= y_1 \int \frac{e^{\int -\frac{-\frac{x}{2}}{-4x^3+x^2} \, dx}}{(y_1)^2} \, dx\\ &= y_1 \int \frac{e^{-\frac{\ln(-1+4x)}{2} + \frac{\ln(x)}{2}}}{(y_1)^2} \, dx\\ &= y_1 \left(\frac{2\,\mathrm{e}^{-\frac{\ln(-1+4x)}{2} + \frac{\ln(1-4x)}{2}} \left(-\left(\sqrt{1 - 4x} + 1\right)^2 + 2\sqrt{1 - 4x} + 2\right)^{3/2}}{3\left(\sqrt{1 - 4x} + 1\right)^3}\right)\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{x^{1/4}\sqrt{2}\left(\sqrt{1-4x}+1\right)\sqrt{\frac{\sqrt{1-4x}+1}{\sqrt{x}}}}{4}\right) \\
&\quad + c_2 \left(\frac{x^{1/4}\sqrt{2}\left(\sqrt{1-4x}+1\right)\sqrt{\frac{\sqrt{1-4x}+1}{\sqrt{x}}}}{4}\right)\left(\frac{2\,\mathrm{e}^{-\frac{\ln(-1+4x)}{2}+\frac{\ln(1-4x)}{2}}\left(-\left(\sqrt{1-4x}+1\right)^2+2\sqrt{1-4x}+2\right)^{3/2}}{3\left(\sqrt{1-4x}+1\right)^3}\right.
\end{aligned}
$$

Will add steps showing solving for IC soon.

Let's solve

$x^2(1-4x)\left(\frac{d^2}{dx^2}y(x)\right)-\frac{x\left(\frac{d}{dx}y(x)\right)}{2}-\frac{3xy(x)}{4}=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x)=-\frac{3y(x)}{4x(4x-1)}-\frac{\frac{d}{dx}y(x)}{2x(4x-1)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x)+\frac{\frac{d}{dx}y(x)}{2x(4x-1)}+\frac{3y(x)}{4x(4x-1)}=0$

□ Check to see if x_0 is a regular singular point

  ∘ Define functions

    $\left[P_2(x)=\frac{1}{2x(4x-1)}, P_3(x)=\frac{3}{4x(4x-1)}\right]$

  ∘ $x\cdot P_2(x)$ is analytic at $x=0$

    $(x\cdot P_2(x))\Big|_{x=0}=-\frac{1}{2}$

  ∘ $x^2\cdot P_3(x)$ is analytic at $x=0$

    $(x^2\cdot P_3(x))\Big|_{x=0}=0$

  ∘ $x=0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=0$

- Multiply by denominators

  $4x(4x-1)\left(\frac{d^2}{dx^2}y(x)\right)+2\frac{d}{dx}y(x)+3y(x)=0$

- Assume series solution for $y(x)$

  $y(x)=\sum_{k=0}^{\infty}a_k x^{k+r}$

□ Rewrite ODE with series expansions

  ∘ Convert $\frac{d}{dx}y(x)$ to series expansion

    $\frac{d}{dx}y(x)=\sum_{k=0}^{\infty}a_k(k+r)\,x^{k+r-1}$

  ∘ Shift index using $k->k+1$

    $\frac{d}{dx}y(x)=\sum_{k=-1}^{\infty}a_{k+1}(k+1+r)\,x^{k+r}$

- Convert $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m = 1..2$

  $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\,x^{k+r-2+m}$

- Shift index using $k- > k+2-m$

  $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\,x^{k+r}$

  Rewrite ODE with series expansions

  $-2a_0r(-3+2r)\,x^{-1+r} + \left(\sum_{k=0}^{\infty} (-2a_{k+1}(k+1+r)(2k-1+2r) + a_k(4k+4r-1)(4k+4r-3))\,x$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $-2r(-3+2r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \left\{0, \frac{3}{2}\right\}$

- Each term in the series must be 0, giving the recursion relation

  $-4(k+1+r)\left(k+r-\frac{1}{2}\right)a_{k+1} + 16\left(k+r-\frac{3}{4}\right)a_k\left(k+r-\frac{1}{4}\right) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+1} = \frac{(4k+4r-3)a_k(4k+4r-1)}{2(k+1+r)(2k-1+2r)}$

- Recursion relation for $r = 0$

  $a_{k+1} = \frac{(4k-3)a_k(4k-1)}{2(k+1)(2k-1)}$

- Solution for $r = 0$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^k, a_{k+1} = \frac{(4k-3)a_k(4k-1)}{2(k+1)(2k-1)}\right]$

- Recursion relation for $r = \frac{3}{2}$

  $a_{k+1} = \frac{(4k+3)a_k(4k+5)}{2\left(k+\frac{5}{2}\right)(2k+2)}$

- Solution for $r = \frac{3}{2}$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+\frac{3}{2}}, a_{k+1} = \frac{(4k+3)a_k(4k+5)}{2\left(k+\frac{5}{2}\right)(2k+2)}\right]$

- Combine solutions and rename parameters

  $\left[y(x) = \left(\sum_{k=0}^{\infty} a_k x^k\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{3}{2}}\right), a_{k+1} = \frac{(4k-3)a_k(4k-1)}{2(k+1)(2k-1)}, b_{k+1} = \frac{(4k+3)b_k(4k+5)}{2\left(k+\frac{5}{2}\right)(2k+2)}\right]$

CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' + (x^2+x)\,y' + (x-9)\,y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.248 (sec)

Writing the ode as

$$x^2y'' + (x^2+x)\,y' + (x-9)\,y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= x^2+x \\ C &= x-9 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2-2x+35}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2-2x+35 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2-2x+35}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.502: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} + \frac{35}{4x^2} - \frac{1}{2x}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{35}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{5}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} - \frac{1}{2x} + \frac{17}{2x^2} + \frac{17}{2x^3} - \frac{255}{4x^4} - \frac{833}{4x^5} + \frac{3213}{4x^6} + \frac{21709}{4x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 - 2x + 35}{4x^2} \\ &= Q + \frac{R}{4x^2} \\ &= \left(\frac{1}{4}\right) + \left(\frac{-2x + 35}{4x^2}\right) \\ &= \frac{1}{4} + \frac{-2x + 35}{4x^2} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is -2. Dividing this by leading coefficient in t which is 4 gives $-\frac{1}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{1}{2}\right) - (0) \\ &= -\frac{1}{2} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &&= -\frac{1}{2} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &&= \frac{1}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2 - 2x + 35}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{7}{2}$	$-\frac{5}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	$-\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = -\frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^+ - (\alpha_{c_1}^-) \\ &= -\frac{1}{2} - \left(-\frac{5}{2}\right) \\ &= 2 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (+)[\sqrt{r}]_\infty \\ &= -\frac{5}{2x} + \left(\frac{1}{2}\right) \\ &= -\frac{5}{2x} + \frac{1}{2} \\ &= \frac{-5+x}{2x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 2$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = x^2 + a_1 x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(2) + 2\left(-\frac{5}{2x} + \frac{1}{2}\right)(2x + a_1) + \left(\left(\frac{5}{2x^2}\right) + \left(-\frac{5}{2x} + \frac{1}{2}\right)^2 - \left(\frac{x^2 - 2x + 35}{4x^2}\right) \right) = 0$$

$$\frac{(-a_1 - 8)\, x - 2a_0 - 5a_1}{x} = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 20, a_1 = -8\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^2 - 8x + 20$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= \left(x^2 - 8x + 20\right) e^{\int \left(-\frac{5}{2x} + \frac{1}{2}\right) dx} \\ &= \left(x^2 - 8x + 20\right) e^{\frac{x}{2} - \frac{5 \ln(x)}{2}} \\ &= \frac{\left(x^2 - 8x + 20\right) e^{\frac{x}{2}}}{x^{5/2}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2} \frac{x^2 + x}{x^2} \, dx} \\ &= z_1 e^{-\frac{x}{2} - \frac{\ln(x)}{2}} \\ &= z_1 \left(\frac{e^{-\frac{x}{2}}}{\sqrt{x}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{x^2 - 8x + 20}{x^3}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{x^2 + x}{x^2} \, dx}}{\left(y_1\right)^2} \, dx \\ &= y_1 \int \frac{e^{-x - \ln(x)}}{\left(y_1\right)^2} \, dx \\ &= y_1 \left(-\frac{\left(x^3 + 9x^2 + 36x + 60\right) x \, e^{-x - \ln(x)}}{x^2 - 8x + 20}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\frac{x^2 - 8x + 20}{x^3}\right) + c_2 \left(\frac{x^2 - 8x + 20}{x^3} \left(-\frac{\left(x^3 + 9x^2 + 36x + 60\right) x \, e^{-x - \ln(x)}}{x^2 - 8x + 20}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2\left(\frac{d^2}{dx^2}y(x)\right)+(x^2+x)\left(\frac{d}{dx}y(x)\right)+(x-9)\,y(x)=0$

- Highest derivative means the order of the ODE is 2

  $y(x)=\sum_{k=0}^{\infty}a_kx^{k+r}$

☐ Rewrite ODE with series expansions

  ◦ Convert $x^m\cdot y(x)$ to series expansion for $m=0..1$

  $x^m\cdot y(x)=\sum_{k=0}^{\infty}a_kx^{k+r+m}$

  ◦ Shift index using $k->k-m$

  $x^m\cdot y(x)=\sum_{k=m}^{\infty}a_{k-m}x^{k+r}$

  ◦ Convert $x^m\cdot\left(\frac{d}{dx}y(x)\right)$ to series expansion for $m=1..2$

  $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,x^{k+r-1+m}$

  ◦ Shift index using $k->k+1-m$

  $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,x^{k+r}$

  ◦ Convert $x^2\cdot\left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

  $x^2\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(3+r)\,(-3+r)\,x^r+\left(\sum_{k=1}^{\infty}\left(a_k(k+r+3)\,(k+r-3)+a_{k-1}(k+r)\right)x^{k+r}\right)=0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$(3+r)(-3+r)=0$

- Values of r that satisfy the indicial equation

  $r \in \{-3, 3\}$
- Each term in the series must be 0, giving the recursion relation

  $a_k(k+r+3)(k+r-3)+a_{k-1}(k+r)=0$
- Shift index using $k->k+1$

  $a_{k+1}(k+4+r)(k-2+r)+a_k(k+r+1)=0$
- Recursion relation that defines series solution to ODE

  $a_{k+1}=-\frac{a_k(k+r+1)}{(k+4+r)(k-2+r)}$
- Recursion relation for $r=-3$; series terminates at $k=2$

  $a_{k+1}=-\frac{a_k(k-2)}{(k+1)(k-5)}$
- Apply recursion relation for $k=0$

  $a_1=-\frac{2a_0}{5}$
- Apply recursion relation for $k=1$

  $a_2=-\frac{a_1}{8}$
- Express in terms of a_0

  $a_2=\frac{a_0}{20}$
- Terminating series solution of the ODE for $r=-3$. Use reduction of order to find the second lin

  $y(x)=a_0\cdot\left(1-\frac{2}{5}x+\frac{1}{20}x^2\right)$
- Recursion relation for $r=3$

  $a_{k+1}=-\frac{a_k(k+4)}{(k+7)(k+1)}$
- Solution for $r=3$

  $\left[y(x)=\sum_{k=0}^{\infty} a_k x^{k+3}, a_{k+1}=-\frac{a_k(k+4)}{(k+7)(k+1)}\right]$
- Combine solutions and rename parameters

  $\left[y(x)=a_0\cdot\left(1-\frac{2}{5}x+\frac{1}{20}x^2\right)+\left(\sum_{k=0}^{\infty} b_k x^{k+3}\right), b_{k+1}=-\frac{b_k(4+k)}{(k+7)(k+1)}\right]$

2.1.264 Problem 267

Internal problem ID [9436]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 267
Date solved : `Monday, January 27, 2025 at 06:02:48 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' + x(x+1)\,y' + (3x-1)\,y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.267 (sec)

Writing the ode as

$$x^2y'' + \left(x^2+x\right)y' + (3x-1)\,y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= x^2 + x \\ C &= 3x - 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 - 10x + 3}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2 - 10x + 3 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2 - 10x + 3}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.504: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} + \frac{3}{4x^2} - \frac{5}{2x}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} - \frac{5}{2x} - \frac{11}{2x^2} - \frac{55}{2x^3} - \frac{671}{4x^4} - \frac{4565}{4x^5} - \frac{33231}{4x^6} - \frac{253275}{4x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 - 10x + 3}{4x^2} \\ &= Q + \frac{R}{4x^2} \\ &= \left(\frac{1}{4}\right) + \left(\frac{-10x + 3}{4x^2}\right) \\ &= \frac{1}{4} + \frac{-10x + 3}{4x^2} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is -10. Dividing this by leading coefficient in t which is 4 gives $-\frac{5}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{5}{2}\right) - (0) \\ &= -\frac{5}{2} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{2} \\ \alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-\frac{5}{2}}{\frac{1}{2}} - 0\right) &= -\frac{5}{2} \\ \alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-\frac{5}{2}}{\frac{1}{2}} - 0\right) &= \frac{5}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2 - 10x + 3}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	$-\frac{5}{2}$	$\frac{5}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{5}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^+\right) \\ &= \frac{5}{2} - \left(\frac{3}{2}\right) \\ &= 1 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{3}{2x} + (-)\left(\frac{1}{2}\right) \\ &= \frac{3}{2x} - \frac{1}{2} \\ &= -\frac{-3+x}{2x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{3}{2x} - \frac{1}{2}\right)(1) + \left(\left(-\frac{3}{2x^2}\right) + \left(\frac{3}{2x} - \frac{1}{2}\right)^2 - \left(\frac{x^2 - 10x + 3}{4x^2}\right)\right) = 0$$

$$\frac{3 + a_0}{x} = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = -3\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = -3 + x$$

Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= pe^{\int \omega\, dx} \\
&= (-3+x)\,\mathrm{e}^{\int \left(\frac{3}{2x}-\frac{1}{2}\right)dx} \\
&= (-3+x)\,\mathrm{e}^{-\frac{x}{2}+\frac{3\ln(x)}{2}} \\
&= (-3+x)\,x^{3/2}\mathrm{e}^{-\frac{x}{2}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{x^2+x}{x^2}\, dx} \\
&= z_1 e^{-\frac{x}{2}-\frac{\ln(x)}{2}} \\
&= z_1 \left(\frac{\mathrm{e}^{-\frac{x}{2}}}{\sqrt{x}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = x\,\mathrm{e}^{-x}(-3+x)
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x^2+x}{x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-x-\ln(x)}}{(y_1)^2}\, dx \\
&= y_1 \left(-\frac{\mathrm{e}^{x}}{27\,(-3+x)} - \frac{\mathrm{Ei}_1(-x)}{6} - \frac{7\,\mathrm{e}^{x}}{54x} - \frac{\mathrm{e}^{x}}{18x^2}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(x\,\mathrm{e}^{-x}(-3+x)\right) + c_2\left(x\,\mathrm{e}^{-x}(-3+x)\left(-\frac{\mathrm{e}^{x}}{27\,(-3+x)} - \frac{\mathrm{Ei}_1(-x)}{6} - \frac{7\,\mathrm{e}^{x}}{54x} - \frac{\mathrm{e}^{x}}{18x^2}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2\left(\frac{d^2}{dx^2}y(x)\right)+x(x+1)\left(\frac{d}{dx}y(x)\right)+(3x-1)\,y(x)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x)=-\frac{(3x-1)y(x)}{x^2}-\frac{(x+1)\left(\frac{d}{dx}y(x)\right)}{x}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x)+\frac{(x+1)\left(\frac{d}{dx}y(x)\right)}{x}+\frac{(3x-1)y(x)}{x^2}=0$

□ Check to see if $x_0=0$ is a regular singular point

- ◦ Define functions

  $\left[P_2(x)=\frac{x+1}{x},P_3(x)=\frac{3x-1}{x^2}\right]$

- ◦ $x\cdot P_2(x)$ is analytic at $x=0$

  $\left.(x\cdot P_2(x))\right|_{x=0}=1$

- ◦ $x^2\cdot P_3(x)$ is analytic at $x=0$

  $\left.(x^2\cdot P_3(x))\right|_{x=0}=-1$

- ◦ $x=0$is a regular singular point

  Check to see if $x_0=0$ is a regular singular point

  $x_0=0$

- Multiply by denominators

  $x^2\left(\frac{d^2}{dx^2}y(x)\right)+x(x+1)\left(\frac{d}{dx}y(x)\right)+(3x-1)\,y(x)=0$

- Assume series solution for $y(x)$

  $y(x)=\sum_{k=0}^{\infty}a_kx^{k+r}$

□ Rewrite ODE with series expansions

- ◦ Convert $x^m\cdot y(x)$ to series expansion for $m=0..1$

  $x^m\cdot y(x)=\sum_{k=0}^{\infty}a_kx^{k+r+m}$

- ◦ Shift index using $k->k-m$

  $x^m\cdot y(x)=\sum_{k=m}^{\infty}a_{k-m}x^{k+r}$

- ◦ Convert $x^m\cdot\left(\frac{d}{dx}y(x)\right)$ to series expansion for $m=1..2$

  $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,x^{k+r-1+m}$

- ◦ Shift index using $k->k+1-m$

  $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,x^{k+r}$

- ◦ Convert $x^2\cdot\left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

  $x^2\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(1+r)\,(-1+r)\,x^r+\left(\sum_{k=1}^{\infty}\left(a_k(k+r+1)\,(k+r-1)+a_{k-1}(k+2+r)\right)x^{k+r}\right)=0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$(1+r)(-1+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{-1, 1\}$
- Each term in the series must be 0, giving the recursion relation

  $a_k(k+r+1)(k+r-1) + a_{k-1}(k+2+r) = 0$
- Shift index using $k- >k+1$

  $a_{k+1}(k+2+r)(k+r) + a_k(k+r+3) = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+1} = -\frac{a_k(k+r+3)}{(k+2+r)(k+r)}$
- Recursion relation for $r = -1$

  $a_{k+1} = -\frac{a_k(k+2)}{(k+1)(k-1)}$
- Series not valid for $r = -1$, division by 0 in the recursion relation at $k = 1$

  $a_{k+1} = -\frac{a_k(k+2)}{(k+1)(k-1)}$
- Recursion relation for $r = 1$

  $a_{k+1} = -\frac{a_k(k+4)}{(k+3)(k+1)}$
- Solution for $r = 1$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+1}, a_{k+1} = -\frac{a_k(k+4)}{(k+3)(k+1)}\right]$

2.1.265 Problem 268

Internal problem ID [9437]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 268
Date solved : `Monday, January 27, 2025 at 06:02:49 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' - (x^2 + 4x)\, y' + 4y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.243 (sec)

Writing the ode as

$$x^2y'' + (-x^2 - 4x)\, y' + 4y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -x^2 - 4x \\ C &= 4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 + 8x + 8}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2 + 8x + 8 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2 + 8x + 8}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.506: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} + \frac{2}{x^2} + \frac{2}{x}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -1 \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} + \frac{2}{x} - \frac{2}{x^2} + \frac{8}{x^3} - \frac{36}{x^4} + \frac{176}{x^5} - \frac{912}{x^6} + \frac{4928}{x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{2}\end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned}r &= \frac{s}{t} \\ &= \frac{x^2 + 8x + 8}{4x^2} \\ &= Q + \frac{R}{4x^2} \\ &= \left(\frac{1}{4}\right) + \left(\frac{8x + 8}{4x^2}\right) \\ &= \frac{1}{4} + \frac{8x + 8}{4x^2}\end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is 8. Dividing this by leading coefficient in t which is 4 gives 2. Now b can be found.

$$\begin{aligned}b &= (2) - (0) \\ &= 2\end{aligned}$$

Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= \frac{1}{2} \\ \alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{2}{\frac{1}{2}} - 0\right) &&= 2 \\ \alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{2}{\frac{1}{2}} - 0\right) &&= -2\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2 + 8x + 8}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	2	-1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	2	-2

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = 2$ then

$$\begin{aligned}
d &= \alpha_\infty^+ - (\alpha_{c_1}^+) \\
&= 2 - (2) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1} \right) + (+)[\sqrt{r}]_\infty \\
&= \frac{2}{x} + \left(\frac{1}{2}\right) \\
&= \frac{1}{2} + \frac{2}{x} \\
&= \frac{x+4}{2x}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned}
(0) + 2\left(\frac{1}{2} + \frac{2}{x}\right)(0) + \left(\left(-\frac{2}{x^2}\right) + \left(\frac{1}{2} + \frac{2}{x}\right)^2 - \left(\frac{x^2+8x+8}{4x^2}\right) \right) &= 0 \\
0 &= 0
\end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= e^{\int \left(\frac{1}{2} + \frac{2}{x}\right) dx} \\
&= x^2 e^{\frac{x}{2}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-x^2-4x}{x^2}\,dx} \\ &= z_1 e^{\frac{x}{2}+2\ln(x)} \\ &= z_1\left(x^2 \mathrm{e}^{\frac{x}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = x^4 \mathrm{e}^x$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-x^2-4x}{x^2}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{x+4\ln(x)}}{(y_1)^2}\,dx \\ &= y_1\left(-\frac{\mathrm{e}^{-x}}{3x^3}+\frac{\mathrm{e}^{-x}}{6x^2}-\frac{\mathrm{e}^{-x}}{6x}+\frac{\mathrm{Ei}_1(x)}{6}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(x^4\mathrm{e}^x\right) + c_2\left(x^4\mathrm{e}^x\left(-\frac{\mathrm{e}^{-x}}{3x^3}+\frac{\mathrm{e}^{-x}}{6x^2}-\frac{\mathrm{e}^{-x}}{6x}+\frac{\mathrm{Ei}_1(x)}{6}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve
$x^2\left(\frac{d^2}{dx^2}y(x)\right) - (x^2+4x)\left(\frac{d}{dx}y(x)\right) + 4y(x) = 0$

- Highest derivative means the order of the ODE is 2
  $\frac{d^2}{dx^2}y(x)$
- Isolate 2nd derivative
  $\frac{d^2}{dx^2}y(x) = -\frac{4y(x)}{x^2} + \frac{(x+4)\left(\frac{d}{dx}y(x)\right)}{x}$
- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea
  $\frac{d^2}{dx^2}y(x) - \frac{(x+4)\left(\frac{d}{dx}y(x)\right)}{x} + \frac{4y(x)}{x^2} = 0$
- ☐ Check to see if $x_0 = 0$ is a regular singular point
  - Define functions
    $\left[P_2(x) = -\frac{x+4}{x}, P_3(x) = \frac{4}{x^2}\right]$
  - $x \cdot P_2(x)$ is analytic at $x = 0$
    $\left(x \cdot P_2(x)\right)\Big|_{x=0} = -4$

- ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $(x^2 \cdot P_3(x))\Big|_{x=0} = 4$

- ◦ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $x^2\left(\frac{d^2}{dx^2}y(x)\right) - x(x+4)\left(\frac{d}{dx}y(x)\right) + 4y(x) = 0$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

- □ Rewrite ODE with series expansions

  - ◦ Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m = 1..2$

    $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1+m}$

  - ◦ Shift index using $k- >k+1-m$

    $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$

  - ◦ Convert $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

    $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(-1+r)(-4+r)\, x^r + \left(\sum_{k=1}^{\infty} \left(a_k(k+r-1)(k+r-4) - a_{k-1}(k+r-1)\right) x^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-1+r)(-4+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{1, 4\}$

- Each term in the series must be 0, giving the recursion relation

  $(k+r-1)\left(a_k(k+r-4) - a_{k-1}\right) = 0$

- Shift index using $k- >k+1$

  $(k+r)\left(a_{k+1}(k-3+r) - a_k\right) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+1} = \frac{a_k}{k-3+r}$

- Recursion relation for $r = 1$

  $a_{k+1} = \frac{a_k}{k-2}$

- Series not valid for $r = 1$, division by 0 in the recursion relation at $k = 2$

  $a_{k+1} = \frac{a_k}{k-2}$

- Recursion relation for $r = 4$

  $a_{k+1} = \frac{a_k}{k+1}$

- Solution for $r = 4$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+4}, a_{k+1} = \frac{a_k}{k+1}\right]$

2.1.266 Problem 269

Internal problem ID [9438]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 269
Date solved : Monday, January 27, 2025 at 06:02:49 PM
CAS classification : [[_2nd_order, _with_linear_symmetries]]

Solve

$$2x^2y'' - (3x+2)\,y' + \frac{(2x-1)\,y}{x} = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.489 (sec)

Writing the ode as

$$2x^2y'' + (-3x-2)\,y' + \left(2-\frac{1}{x}\right)y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2x^2 \\ B &= -3x-2 \\ C &= 2-\frac{1}{x} \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{5x^2+36x+4}{16x^4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 5x^2+36x+4 \\ t &= 16x^4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{5x^2 + 36x + 4}{16x^4}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.508: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16x^4$. There is a pole at $x = 0$ of order 4. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Looking at higher order poles of order $2v \geq 4$ (must be even order for case one).Then for each pole c, $[\sqrt{r}]_c$ is the sum of terms $\frac{1}{(x-c)^i}$ for $2 \leq i \leq v$ in the Laurent series expansion of $\sqrt{r}$ expanded around each pole c. Hence

$$[\sqrt{r}]_c = \sum_{2}^{v} \frac{a_i}{(x-c)^i} \tag{1B}$$

Let a be the coefficient of the term $\frac{1}{(x-c)^v}$ in the above where v is the pole order divided by 2. Let b be the coefficient of $\frac{1}{(x-c)^{v+1}}$ in r minus the coefficient of $\frac{1}{(x-c)^{v+1}}$ in $[\sqrt{r}]_c$. Then

$$\begin{aligned} \alpha_c^+ &= \frac{1}{2}\left(\frac{b}{a} + v\right) \\ \alpha_c^- &= \frac{1}{2}\left(-\frac{b}{a} + v\right) \end{aligned}$$

The partial fraction decomposition of r is

$$r = \frac{9}{4x^3} + \frac{1}{4x^4} + \frac{5}{16x^2}$$

There is pole in r at $x = 0$ of order 4, hence $v = 2$. Expanding $\sqrt{r}$ as Laurent series about this pole $c = 0$ gives

$$[\sqrt{r}]_c \approx \frac{1}{2x^2} + \frac{9}{4x} - \frac{19}{4} + \frac{171x}{8} - \frac{475x^2}{4} + \frac{11799x^3}{16} + \dots \tag{2B}$$

Using eq. (1B), taking the sum up to $v = 2$ the above becomes

$$[\sqrt{r}]_c = \frac{1}{2x^2} \tag{3B}$$

The above shows that the coefficient of $\frac{1}{(x-0)^2}$ is

$$a = \frac{1}{2}$$

Now we need to find b. let b be the coefficient of the term $\frac{1}{(x-c)^{v+1}}$ in r minus the coefficient of the same term but in the sum $[\sqrt{r}]_c$ found in eq. (3B). Here c is current pole which is $c = 0$. This term becomes $\frac{1}{x^3}$. The coefficient of this term in the sum $[\sqrt{r}]_c$ is seen to be 0 and the coefficient of this term r is found from the partial fraction decomposition from above to be $\frac{9}{4}$. Therefore

$$\begin{aligned} b &= \left(\frac{9}{4}\right) - (0) \\ &= \frac{9}{4} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_c &= \frac{1}{2x^2} \\ \alpha_c^+ &= \frac{1}{2}\left(\frac{b}{a} + v\right) = \frac{1}{2}\left(\frac{\frac{9}{4}}{\frac{1}{2}} + 2\right) = \frac{13}{4} \\ \alpha_c^- &= \frac{1}{2}\left(-\frac{b}{a} + v\right) = \frac{1}{2}\left(-\frac{\frac{9}{4}}{\frac{1}{2}} + 2\right) = -\frac{5}{4} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{5x^2 + 36x + 4}{16x^4}$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{5}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{4} \\ \alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{4} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{5x^2 + 36x + 4}{16x^4}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	4	$\frac{1}{2x^2}$	$\frac{13}{4}$	$-\frac{5}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{5}{4}$	$-\frac{1}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -\frac{1}{4}$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\ &= -\frac{1}{4} - \left(-\frac{5}{4}\right) \\ &= 1 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + (-)[\sqrt{r}]_\infty \\ &= -\frac{1}{2x^2} - \frac{5}{4x} + (-)(0) \\ &= -\frac{1}{2x^2} - \frac{5}{4x} \\ &= \frac{-2-5x}{4x^2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{2x^2} - \frac{5}{4x}\right)(1) + \left(\left(\frac{1}{x^3} + \frac{5}{4x^2}\right) + \left(-\frac{1}{2x^2} - \frac{5}{4x}\right)^2 - \left(\frac{5x^2+36x+4}{16x^4}\right)\right) = 0$$

$$\frac{-2+5a_0}{2x^2} = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\left\{a_0 = \frac{2}{5}\right\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x + \frac{2}{5}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= \left(x + \frac{2}{5}\right) \mathrm{e}^{\int \left(-\frac{1}{2x^2} - \frac{5}{4x}\right) dx} \\ &= \left(x + \frac{2}{5}\right) \mathrm{e}^{\frac{1}{2x} - \frac{5 \ln(x)}{4}} \\ &= \frac{(2 + 5x)\, \mathrm{e}^{\frac{1}{2x}}}{5x^{5/4}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2} \frac{-3x-2}{2x^2} \, dx} \\ &= z_1 e^{-\frac{1}{2x} + \frac{3 \ln(x)}{4}} \\ &= z_1 \left(x^{3/4} \mathrm{e}^{-\frac{1}{2x}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{2 + 5x}{5\sqrt{x}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-3x-2}{2x^2} \, dx}}{(y_1)^2} \, dx \\ &= y_1 \int \frac{e^{-\frac{1}{x} + \frac{3 \ln(x)}{2}}}{(y_1)^2} \, dx \\ &= y_1 \left(\int \frac{25\, \mathrm{e}^{-\frac{1}{x} + \frac{3 \ln(x)}{2}} x}{(2 + 5x)^2} dx \right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\frac{2 + 5x}{5\sqrt{x}}\right) + c_2 \left(\frac{2 + 5x}{5\sqrt{x}} \left(\int \frac{25\, \mathrm{e}^{-\frac{1}{x} + \frac{3 \ln(x)}{2}} x}{(2 + 5x)^2} dx \right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

2.1.267 Problem 270

Internal problem ID [9439]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 270
Date solved : `Monday, January 27, 2025 at 06:02:50 PM`
CAS classification : `[_Jacobi]`

Solve

$$x(1-x)\,y''+\left(\frac{3}{2}-2x\right)y'-\frac{y}{4}=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.229 (sec)

Writing the ode as

$$\left(-x^2+x\right)y''+\left(\frac{3}{2}-2x\right)y'-\frac{y}{4}=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A&=-x^2+x\\ B&=\frac{3}{2}-2x\\ C&=-\frac{1}{4} \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r&=\frac{s}{t}\\ &=\frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{-4x^2+4x-3}{16\left(x^2-x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s&=-4x^2+4x-3\\ t&=16\left(x^2-x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{-4x^2+4x-3}{16\left(x^2-x\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.509: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16(x^2-x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = 1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{8x} - \frac{3}{16x^2} + \frac{1}{-8+8x} - \frac{3}{16\left(-1+x\right)^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{4} \end{aligned}$$

For the pole at $x = 1$ let b be the coefficient of $\frac{1}{(-1+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{4} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{4}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = \frac{-4x^2 + 4x - 3}{16\left(x^2 - x\right)^2}
$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{1}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{-4x^2 + 4x - 3}{16\left(x^2 - x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{3}{4}$	$\frac{1}{4}$
1	2	0	$\frac{3}{4}$	$\frac{1}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^-\right) \\
&= \frac{1}{2} - \left(\frac{1}{2}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2}\right) + (-)[\sqrt{r}]_\infty \\
&= \frac{1}{4x} + \frac{1}{-4+4x} + (-)(0) \\
&= \frac{1}{4x} + \frac{1}{-4+4x} \\
&= \frac{2x-1}{4x(-1+x)}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(0) + 2\left(\frac{1}{4x} + \frac{1}{-4+4x}\right)(0) + \left(\left(-\frac{1}{4x^2} - \frac{1}{4(-1+x)^2}\right) + \left(\frac{1}{4x} + \frac{1}{-4+4x}\right)^2 - \left(\frac{-4x^2+4x-3}{16(x^2-x)^2}\right)\right) = 0
$$

$$
0 = 0
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx} \\
&= e^{\int \left(\frac{1}{4x} + \frac{1}{-4+4x}\right) dx} \\
&= (x(-1+x))^{1/4}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{\frac{3}{2}-2x}{-x^2+x}\, dx} \\
&= z_1 e^{-\frac{\ln(-1+x)}{4} - \frac{3\ln(x)}{4}} \\
&= z_1 \left(\frac{1}{(-1+x)^{1/4}\, x^{3/4}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{(x(-1+x))^{1/4}}{(-1+x)^{1/4}\, x^{3/4}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{\frac{3}{2}-2x}{-x^2+x}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-\frac{\ln(-1+x)}{2} - \frac{3\ln(x)}{2}}}{(y_1)^2}\, dx \\
&= y_1 \left(\ln\left(-\frac{1}{2} + x + \sqrt{x^2-x}\right)\right)
\end{aligned}
$$

Therefore the solution is

$$\begin{aligned}y &= c_1y_1 + c_2y_2\\ &= c_1\left(\frac{(x(-1+x))^{1/4}}{(-1+x)^{1/4}\,x^{3/4}}\right) + c_2\left(\frac{(x(-1+x))^{1/4}}{(-1+x)^{1/4}\,x^{3/4}}\left(\ln\left(-\frac{1}{2}+x+\sqrt{x^2-x}\right)\right)\right)\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x(1-x)\left(\frac{d^2}{dx^2}y(x)\right) + \left(\frac{3}{2}-2x\right)\left(\frac{d}{dx}y(x)\right) - \frac{y(x)}{4} = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{y(x)}{4x(x-1)} - \frac{(4x-3)\left(\frac{d}{dx}y(x)\right)}{2x(x-1)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x) + \frac{(4x-3)\left(\frac{d}{dx}y(x)\right)}{2x(x-1)} + \frac{y(x)}{4x(x-1)} = 0$

- □ Check to see if x_0 is a regular singular point
  - Define functions

    $\left[P_2(x) = \frac{4x-3}{2x(x-1)}, P_3(x) = \frac{1}{4x(x-1)}\right]$
  - $x \cdot P_2(x)$ is analytic at $x = 0$

    $(x \cdot P_2(x))\Big|_{x=0} = \frac{3}{2}$
  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $(x^2 \cdot P_3(x))\Big|_{x=0} = 0$
  - $x = 0$is a regular singular point

    Check to see if x_0 is a regular singular point

    $x_0 = 0$

- Multiply by denominators

  $4x(x-1)\left(\frac{d^2}{dx^2}y(x)\right) + (8x-6)\left(\frac{d}{dx}y(x)\right) + y(x) = 0$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

- □ Rewrite ODE with series expansions
  - Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m = 0..1$

    $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$
  - Shift index using $k->k+1-m$

    $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$
  - Convert $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m = 1..2$

    $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\,x^{k+r-2+m}$
  - Shift index using $k->k+2-m$

$$x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$$

Rewrite ODE with series expansions

$$-2a_0r(1+2r)\,x^{-1+r} + \left(\sum_{k=0}^{\infty} \left(-2a_{k+1}(k+1+r)\,(2k+3+2r) + a_k(2k+2r+1)^2\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $-2r(1+2r) = 0$
- Values of r that satisfy the indicial equation
  $r \in \left\{0, -\frac{1}{2}\right\}$
- Each term in the series must be 0, giving the recursion relation
  $a_k(2k+2r+1)^2 - 4(k+1+r)\left(k+r+\frac{3}{2}\right)a_{k+1} = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+1} = \frac{a_k(2k+2r+1)^2}{2(k+1+r)(2k+3+2r)}$
- Recursion relation for $r = 0$
  $a_{k+1} = \frac{a_k(2k+1)^2}{2(k+1)(2k+3)}$
- Solution for $r = 0$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^k, a_{k+1} = \frac{a_k(2k+1)^2}{2(k+1)(2k+3)}\right]$
- Recursion relation for $r = -\frac{1}{2}$
  $a_{k+1} = \frac{2a_k k^2}{\left(k+\frac{1}{2}\right)(2k+2)}$
- Solution for $r = -\frac{1}{2}$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k-\frac{1}{2}}, a_{k+1} = \frac{2a_k k^2}{\left(k+\frac{1}{2}\right)(2k+2)}\right]$
- Combine solutions and rename parameters
  $\left[y(x) = \left(\sum_{k=0}^{\infty} a_k x^k\right) + \left(\sum_{k=0}^{\infty} b_k x^{k-\frac{1}{2}}\right), a_{k+1} = \frac{a_k(2k+1)^2}{2(k+1)(2k+3)}, b_{k+1} = \frac{2b_k k^2}{\left(k+\frac{1}{2}\right)(2k+2)}\right]$

2.1.268 Problem 271

Internal problem ID [9440]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 271
Date solved : `Monday, January 27, 2025 at 06:02:51 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$2x(1-x)\,y''+xy'-y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.229 (sec)

Writing the ode as

$$\left(-2x^2+2x\right)y''+xy'-y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A&=-2x^2+2x\\ B&=x\\ C&=-1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r&=\frac{s}{t}\\ &=\frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{-3x+8}{16x\left(-1+x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s&=-3x+8\\ t&=16x(-1+x)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{-3x+8}{16x\left(-1+x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.511: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 3 - 1 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16x(-1+x)^2$. There is a pole at $x = 0$ of order 1. There is a pole at $x = 1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 1. For the pole at $x = 0$ of order 1 then

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= 1 \\ \alpha_c^- &= 1 \end{aligned}$$

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{2x} - \frac{1}{2(-1+x)} + \frac{5}{16(-1+x)^2}$$

For the pole at $x = 1$ let b be the coefficient of $\frac{1}{(-1+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{5}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{4} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{-3x + 8}{16x(-1+x)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{3}{16}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{4} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{4}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{-3x + 8}{16x(-1+x)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	1	0	0	1
1	2	0	$\frac{5}{4}$	$-\frac{1}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{3}{4}$	$\frac{1}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{3}{4}$ then

$$\begin{aligned}
d &= \alpha_\infty^+ - (\alpha_{c_1}^- + \alpha_{c_2}^-) \\
&= \frac{3}{4} - \left(\frac{3}{4}\right) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2} \right) + (+)[\sqrt{r}]_\infty \\
&= \frac{1}{x} - \frac{1}{4(-1+x)} + (0) \\
&= \frac{1}{x} - \frac{1}{4(-1+x)} \\
&= \frac{1}{x} - \frac{1}{-4+4x}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{x} - \frac{1}{4(-1+x)}\right)(0) + \left(\left(-\frac{1}{x^2} + \frac{1}{4(-1+x)^2}\right) + \left(\frac{1}{x} - \frac{1}{4(-1+x)}\right)^2 - \left(\frac{-3x+8}{16x(-1+x)^2}\right)\right) =$$
$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega\, dx} \\ &= e^{\int \left(\frac{1}{x} - \frac{1}{4(-1+x)}\right) dx} \\ &= \frac{x}{(-1+x)^{1/4}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{x}{-2x^2+2x}\, dx} \\ &= z_1 e^{\frac{\ln(-1+x)}{4}} \\ &= z_1\left((-1+x)^{1/4}\right) \end{aligned}$$

Which simplifies to

$$y_1 = x$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{x}{-2x^2+2x}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{\frac{\ln(-1+x)}{2}}}{(y_1)^2}\, dx \\ &= y_1\left(-\frac{\sqrt{-1+x}}{x} + \arctan\left(\sqrt{-1+x}\right)\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(x) + c_2\left(x\left(-\frac{\sqrt{-1+x}}{x} + \arctan\left(\sqrt{-1+x}\right)\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

2.1.269 Problem 272

Internal problem ID [9441]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 272
Date solved : `Monday, January 27, 2025 at 06:02:52 PM`
CAS classification : `[_Jacobi]`

Solve

$$2x(1-x)\,y''+(1-11x)\,y'-10y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.212 (sec)

Writing the ode as

$$\left(-2x^2+2x\right)y''+(1-11x)\,y'-10y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A&=-2x^2+2x\\ B&=1-11x\\ C&=-10 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r&=\frac{s}{t}\\ &=\frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{-3x^2+66x-3}{16\left(x^2-x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s&=-3x^2+66x-3\\ t&=16\left(x^2-x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{-3x^2+66x-3}{16\left(x^2-x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.512: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16(x^2 - x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = 1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{15}{4\left(-1+x\right)^{2}} + \frac{15}{4x} - \frac{3}{16x^{2}} - \frac{15}{4\left(-1+x\right)}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^{+} &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{4} \\ \alpha_c^{-} &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{4} \end{aligned}$$

For the pole at $x = 1$ let b be the coefficient of $\frac{1}{(-1+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{15}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^{+} &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{2} \\ \alpha_c^{-} &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{2} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{-3x^2 + 66x - 3}{16\left(x^2 - x\right)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{3}{16}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{4} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{4}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{-3x^2 + 66x - 3}{16\left(x^2 - x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{3}{4}$	$\frac{1}{4}$
1	2	0	$\frac{5}{2}$	$-\frac{3}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{3}{4}$	$\frac{1}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{4}$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^+ + \alpha_{c_2}^-\right) \\
&= \frac{1}{4} - \left(-\frac{3}{4}\right) \\
&= 1
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2} \right) + (-)[\sqrt{r}]_\infty \\
&= \frac{3}{4x} - \frac{3}{2(-1+x)} + (-)(0) \\
&= \frac{3}{4x} - \frac{3}{2(-1+x)} \\
&= -\frac{3(x+1)}{4x(-1+x)}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p''+2\omega p'+\left(\omega'+\omega^2-r\right)p=0 \tag{1A}$$

Let

$$p(x)=x+a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(\frac{3}{4x}-\frac{3}{2\left(-1+x\right)}\right)(1)+\left(\left(-\frac{3}{4x^2}+\frac{3}{2\left(-1+x\right)^2}\right)+\left(\frac{3}{4x}-\frac{3}{2\left(-1+x\right)}\right)^2-\left(\frac{-3x^2+66x-3}{16\left(x^2-x\right)^2}\right)\right.$$
$$\frac{-3+3a_0}{2x\left(-1+x\right)}=$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0=1\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x)=x+1$$

Therefore the first solution to the ode $z''=rz$ is

$$\begin{aligned}
z_1(x)&=pe^{\int\omega\,dx}\\
&=(x+1)\,e^{\int\left(\frac{3}{4x}-\frac{3}{2(-1+x)}\right)dx}\\
&=(x+1)\,e^{-\frac{3\ln(-1+x)}{2}+\frac{3\ln(x)}{4}}\\
&=\frac{(x+1)\,x^{3/4}}{\left(-1+x\right)^{3/2}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1&=z_1e^{\int-\frac{1}{2}\frac{B}{A}\,dx}\\
&=z_1e^{-\int\frac{1}{2}\frac{1-11x}{-2x^2+2x}\,dx}\\
&=z_1e^{-\frac{5\ln(-1+x)}{2}-\frac{\ln(x)}{4}}\\
&=z_1\left(\frac{1}{\left(-1+x\right)^{5/2}x^{1/4}}\right)
\end{aligned}$$

Which simplifies to

$$y_1=\frac{\sqrt{x}\,(x+1)}{\left(-1+x\right)^4}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2=y_1\int\frac{e^{\int-\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2&=y_1\int\frac{e^{\int-\frac{1-11x}{-2x^2+2x}\,dx}}{\left(y_1\right)^2}\,dx\\
&=y_1\int\frac{e^{-5\ln(-1+x)-\frac{\ln(x)}{2}}}{\left(y_1\right)^2}\,dx\\
&=y_1\left(\frac{2(x^2+6x+1)\left(-1+x\right)^5e^{-5\ln(-1+x)-\frac{\ln(x)}{2}}}{x+1}\right)
\end{aligned}$$

Therefore the solution is

$$y = c_1y_1 + c_2y_2$$
$$= c_1\left(\frac{\sqrt{x}\,(x+1)}{(-1+x)^4}\right) + c_2\left(\frac{\sqrt{x}\,(x+1)}{(-1+x)^4}\left(\frac{2(x^2+6x+1)\,(-1+x)^5\,\mathrm{e}^{-5\ln(-1+x)-\frac{\ln(x)}{2}}}{x+1}\right)\right)$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve
$2x(1-x)\left(\frac{d^2}{dx^2}y(x)\right) + (1-11x)\left(\frac{d}{dx}y(x)\right) - 10y(x) = 0$

- Highest derivative means the order of the ODE is 2
  $\frac{d^2}{dx^2}y(x)$
- Isolate 2nd derivative
  $\frac{d^2}{dx^2}y(x) = -\frac{5y(x)}{x(x-1)} - \frac{(11x-1)\left(\frac{d}{dx}y(x)\right)}{2x(x-1)}$
- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin
  $\frac{d^2}{dx^2}y(x) + \frac{(11x-1)\left(\frac{d}{dx}y(x)\right)}{2x(x-1)} + \frac{5y(x)}{x(x-1)} = 0$
- □ Check to see if x_0 is a regular singular point
  - ◦ Define functions
    $\left[P_2(x) = \frac{11x-1}{2x(x-1)}, P_3(x) = \frac{5}{x(x-1)}\right]$
  - ◦ $x \cdot P_2(x)$ is analytic at $x = 0$
    $\left.(x \cdot P_2(x))\right|_{x=0} = \frac{1}{2}$
  - ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$
    $\left.(x^2 \cdot P_3(x))\right|_{x=0} = 0$
  - ◦ $x = 0$is a regular singular point
    Check to see if x_0 is a regular singular point
    $x_0 = 0$
- Multiply by denominators
  $2x(x-1)\left(\frac{d^2}{dx^2}y(x)\right) + (11x-1)\left(\frac{d}{dx}y(x)\right) + 10y(x) = 0$
- Assume series solution for $y(x)$
  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$
- □ Rewrite ODE with series expansions
  - ◦ Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m = 0..1$
    $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$
  - ◦ Shift index using $k->k+1-m$
    $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$
  - ◦ Convert $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m = 1..2$
    $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\,x^{k+r-2+m}$
  - ◦ Shift index using $k->k+2-m$

$$x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$$

Rewrite ODE with series expansions

$$-a_0 r(-1+2r)\,x^{-1+r} + \left(\sum_{k=0}^{\infty} \left(-a_{k+1}(k+1+r)\,(2k+1+2r) + a_k(2k+2r+5)\,(k+r+2)\right) x^{k+r}\right)$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$-r(-1+2r) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \left\{0, \frac{1}{2}\right\}$$

- Each term in the series must be 0, giving the recursion relation

$$-2(k+1+r)\left(k+r+\frac{1}{2}\right)a_{k+1} + 2(k+r+2)\left(k+r+\frac{5}{2}\right)a_k = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1} = \frac{(k+r+2)(2k+2r+5)a_k}{(k+1+r)(2k+1+2r)}$$

- Recursion relation for $r=0$

$$a_{k+1} = \frac{(k+2)(2k+5)a_k}{(k+1)(2k+1)}$$

- Solution for $r=0$

$$\left[y(x) = \sum_{k=0}^{\infty} a_k x^k, a_{k+1} = \frac{(k+2)(2k+5)a_k}{(k+1)(2k+1)}\right]$$

- Recursion relation for $r=\frac{1}{2}$

$$a_{k+1} = \frac{\left(k+\frac{5}{2}\right)(2k+6)a_k}{\left(k+\frac{3}{2}\right)(2k+2)}$$

- Solution for $r=\frac{1}{2}$

$$\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}, a_{k+1} = \frac{\left(k+\frac{5}{2}\right)(2k+6)a_k}{\left(k+\frac{3}{2}\right)(2k+2)}\right]$$

- Combine solutions and rename parameters

$$\left[y(x) = \left(\sum_{k=0}^{\infty} a_k x^k\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{2}}\right), a_{k+1} = \frac{(k+2)(2k+5)a_k}{(k+1)(2k+1)}, b_{k+1} = \frac{\left(k+\frac{5}{2}\right)(2k+6)b_k}{\left(k+\frac{3}{2}\right)(2k+2)}\right]$$

2.1.270 Problem 273

Internal problem ID [9442]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 273
Date solved : Monday, January 27, 2025 at 06:02:52 PM
CAS classification : [_Jacobi]

Solve

$$x(1-x)\,y''+\frac{(1-2x)\,y'}{3}+\frac{20y}{9}=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.234 (sec)

Writing the ode as

$$\left(-x^2+x\right)y''+\left(-\frac{2x}{3}+\frac{1}{3}\right)y'+\frac{20y}{9}=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=-x^2+x\\ B&=-\frac{2x}{3}+\frac{1}{3}\\ C&=\frac{20}{9}\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned}r&=\frac{s}{t}\\ &=\frac{2AB'-2BA'+B^2-4AC}{4A^2}\end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{72x^2-72x-5}{36\left(x^2-x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned}s&=72x^2-72x-5\\ t&=36\left(x^2-x\right)^2\end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{72x^2 - 72x - 5}{36\left(x^2 - x\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.514: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 36(x^2 - x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = 1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{41}{18x} - \frac{5}{36\left(-1+x\right)^2} + \frac{41}{18\left(-1+x\right)} - \frac{5}{36x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{5}{36}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{6} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{6} \end{aligned}$$

For the pole at $x = 1$ let b be the coefficient of $\frac{1}{(-1+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{5}{36}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{6} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{6}
\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{72x^2 - 72x - 5}{36\left(x^2 - x\right)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = 2$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -1
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{72x^2 - 72x - 5}{36\left(x^2 - x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{5}{6}$	$\frac{1}{6}$
1	2	0	$\frac{5}{6}$	$\frac{1}{6}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	2	-1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = 2$ then

$$\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^- + \alpha_{c_2}^+\right) \\
&= 2 - (1) \\
&= 1
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1}\right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{+}}{x - c_2}\right) + (+)[\sqrt{r}]_{\infty} \\
&= \frac{1}{6x} + \frac{5}{6\left(-1+x\right)} + (0) \\
&= \frac{1}{6x} + \frac{5}{6\left(-1+x\right)} \\
&= \frac{-1+6x}{6x\left(-1+x\right)}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = x + a_0 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(0) + 2\left(\frac{1}{6x} + \frac{5}{6\left(-1+x\right)}\right)(1) + \left(\left(-\frac{1}{6x^2} - \frac{5}{6\left(-1+x\right)^2}\right) + \left(\frac{1}{6x} + \frac{5}{6\left(-1+x\right)}\right)^2 - \left(\frac{72x^2 - 72x - 5}{36\left(x^2-x\right)^2}\right.\right.
$$

$$
\frac{-1-6a_0}{3x\left(-1+x\right)}
$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$
\left\{a_0 = -\frac{1}{6}\right\}
$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$
p(x) = -\frac{1}{6} + x
$$

Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \left(-\frac{1}{6} + x\right) \mathrm{e}^{\int \left(\frac{1}{6x} + \frac{5}{6(-1+x)}\right) dx} \\
&= \left(-\frac{1}{6} + x\right) \mathrm{e}^{\frac{\ln(x)}{6} + \frac{5\ln(-1+x)}{6}} \\
&= \left(-\frac{1}{6} + x\right) x^{1/6}(-1+x)^{5/6}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-\frac{2x}{3}+\frac{1}{3}}{-x^2+x}\, dx} \\
&= z_1 e^{-\frac{\ln(x(-1+x))}{6}} \\
&= z_1 \left(\frac{1}{\left(x\left(-1+x\right)\right)^{1/6}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{\left(-1+6x\right) x^{1/6}(-1+x)^{5/6}}{6\left(x\left(-1+x\right)\right)^{1/6}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-\frac{2x}{3}+\frac{1}{3}}{-x^2+x}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-\frac{\ln(x(-1+x))}{3}}}{(y_1)^2}\, dx \\ &= y_1 \left(-\frac{54x^{2/3}(-5+6x)}{5\,(-1+6x)\,(-1+x)^{2/3}}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\frac{(-1+6x)\, x^{1/6}(-1+x)^{5/6}}{6\,(x\,(-1+x))^{1/6}}\right) + c_2 \left(\frac{(-1+6x)\, x^{1/6}(-1+x)^{5/6}}{6\,(x\,(-1+x))^{1/6}}\left(-\frac{54x^{2/3}(-5+6x)}{5\,(-1+6x)\,(-1+x)^{2/3}}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x(1-x)\left(\frac{d^2}{dx^2}y(x)\right) + \frac{(-2x+1)\left(\frac{d}{dx}y(x)\right)}{3} + \frac{20y(x)}{9} = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = \frac{20y(x)}{9x(x-1)} - \frac{(2x-1)\left(\frac{d}{dx}y(x)\right)}{3x(x-1)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x) + \frac{(2x-1)\left(\frac{d}{dx}y(x)\right)}{3x(x-1)} - \frac{20y(x)}{9x(x-1)} = 0$

- ☐ Check to see if x_0 is a regular singular point
  - Define functions

    $\left[P_2(x) = \frac{2x-1}{3x(x-1)}, P_3(x) = -\frac{20}{9x(x-1)}\right]$

  - $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left.(x \cdot P_2(x))\right|_{x=0} = \frac{1}{3}$

  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $\left.(x^2 \cdot P_3(x))\right|_{x=0} = 0$

  - $x = 0$is a regular singular point

    Check to see if x_0 is a regular singular point

    $x_0 = 0$

- Multiply by denominators

  $9x(x-1)\left(\frac{d^2}{dx^2}y(x)\right) + (6x-3)\left(\frac{d}{dx}y(x)\right) - 20y(x) = 0$

- Assume series solution for $y(x)$

  $y(x)=\sum_{k=0}^{\infty} a_k x^{k+r}$

- ☐ Rewrite ODE with series expansions
  - Convert $x^m\cdot\left(\frac{d}{dx}y(x)\right)$ to series expansion for $m=0..1$

    $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$
  - Shift index using $k->k+1-m$

    $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$
  - Convert $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m=1..2$

    $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r-2+m}$
  - Shift index using $k->k+2-m$

    $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$

  Rewrite ODE with series expansions

  $-3a_0r(-2+3r)\,x^{-1+r}+\left(\sum_{k=0}^{\infty}(-3a_{k+1}(k+1+r)\,(3k+1+3r)+a_k(3k+3r+4)\,(3k+3r-5\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $-3r(-2+3r)=0$
- Values of r that satisfy the indicial equation

  $r\in\left\{0,\frac{2}{3}\right\}$
- Each term in the series must be 0, giving the recursion relation

  $-9\left(k+r+\frac{1}{3}\right)(k+1+r)\,a_{k+1}+9\left(k+\frac{4}{3}+r\right)\left(k+r-\frac{5}{3}\right)a_k=0$
- Recursion relation that defines series solution to ODE

  $a_{k+1}=\frac{(3k+3r+4)(3k+3r-5)a_k}{3(3k+1+3r)(k+1+r)}$
- Recursion relation for $r=0$

  $a_{k+1}=\frac{(3k+4)(3k-5)a_k}{3(3k+1)(k+1)}$
- Solution for $r=0$

  $\left[y(x)=\sum_{k=0}^{\infty} a_k x^k, a_{k+1}=\frac{(3k+4)(3k-5)a_k}{3(3k+1)(k+1)}\right]$
- Recursion relation for $r=\frac{2}{3}$; series terminates at $k=1$

  $a_{k+1}=\frac{(3k+6)(3k-3)a_k}{3(3k+3)\left(k+\frac{5}{3}\right)}$
- Apply recursion relation for $k=0$

  $a_1=-\frac{6a_0}{5}$
- Terminating series solution of the ODE for $r=\frac{2}{3}$. Use reduction of order to find the second li

  $y(x)=a_0\cdot\left(-\frac{6x}{5}+1\right)$
- Combine solutions and rename parameters

  $\left[y(x)=\left(\sum_{k=0}^{\infty} a_k x^k\right)+b_0\cdot\left(-\frac{6x}{5}+1\right), a_{k+1}=\frac{(3k+4)(3k-5)a_k}{3(3k+1)(k+1)}\right]$

CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$4y''+\frac{3(-x^2+2)\,y}{(-x^2+1)^2}=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.181 (sec)

Writing the ode as

$$4y''+\frac{(-3x^2+6)\,y}{(x^2-1)^2}=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A&=4\\ B&=0\\ C&=\frac{-3x^2+6}{(x^2-1)^2} \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r&=\frac{s}{t}\\ &=\frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{3x^2-6}{4(x^2-1)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s&=3x^2-6\\ t&=4\left(x^2-1\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{3x^2 - 6}{4\left(x^2 - 1\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.516: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^2 - 1)^2$. There is a pole at $x = 1$ of order 2. There is a pole at $x = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{9}{16\,(x-1)} - \frac{9}{16\,(x+1)} - \frac{3}{16\,(x+1)^2} - \frac{3}{16\,(x-1)^2}$$

For the pole at $x = 1$ let b be the coefficient of $\frac{1}{(x-1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^{+} &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{4} \\ \alpha_c^{-} &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{4} \end{aligned}$$

For the pole at $x = -1$ let b be the coefficient of $\frac{1}{(x+1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{4} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{4}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = \frac{3x^2 - 6}{4(x^2-1)^2}
$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{3}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{3x^2 - 6}{4(x^2-1)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
1	2	0	$\frac{3}{4}$	$\frac{1}{4}$
-1	2	0	$\frac{3}{4}$	$\frac{1}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{3}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^+ + \alpha_{c_2}^+\right) \\
&= \frac{3}{2} - \left(\frac{3}{2}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x-c_1}\right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{+}}{x-c_2}\right) + (+)[\sqrt{r}]_{\infty} \\
&= \frac{3}{4(x-1)} + \frac{3}{4(x+1)} + (0) \\
&= \frac{3}{4(x-1)} + \frac{3}{4(x+1)} \\
&= \frac{3x}{2x^2-2}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\,p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{3}{4(x-1)} + \frac{3}{4(x+1)}\right)(0) + \left(\left(-\frac{3}{4(x-1)^2} - \frac{3}{4(x+1)^2}\right) + \left(\frac{3}{4(x-1)} + \frac{3}{4(x+1)}\right)^2 - \left(\frac{3x^2}{4(x^2}\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx} \\
&= e^{\int \left(\frac{3}{4(x-1)} + \frac{3}{4(x+1)}\right) dx} \\
&= (x^2-1)^{3/4}
\end{aligned}$$

The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned}
y_1 &= z_1 \\
&= (x^2-1)^{3/4}
\end{aligned}$$

Which simplifies to

$$y_1 = (x^2-1)^{3/4}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned}
y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\
&= (x^2-1)^{3/4} \int \frac{1}{(x^2-1)^{3/2}}\, dx \\
&= (x^2-1)^{3/4} \left(-\frac{(x-1)(x+1)x}{(x^2-1)^{3/2}}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\left(x^2-1\right)^{3/4}\right) + c_2\left(\left(x^2-1\right)^{3/4}\left(-\frac{(x-1)\,(x+1)\,x}{\left(x^2-1\right)^{3/2}}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$4\frac{d^2}{dx^2}y(x) + \frac{3(-x^2+2)y(x)}{(-x^2+1)^2} = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = \frac{3(x^2-2)y(x)}{4(x^2-1)^2}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x) - \frac{3(x^2-2)y(x)}{4(x^2-1)^2} = 0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

    $\left[P_2(x) = 0, P_3(x) = -\frac{3(x^2-2)}{4(x^2-1)^2}\right]$

  ◦ $(x+1)\cdot P_2(x)$ is analytic at $x=-1$

    $\left((x+1)\cdot P_2(x)\right)\bigg|_{x=-1} = 0$

  ◦ $(x+1)^2\cdot P_3(x)$ is analytic at $x=-1$

    $\left((x+1)^2\cdot P_3(x)\right)\bigg|_{x=-1} = \frac{3}{16}$

  ◦ $x=-1$is a regular singular point

    Check to see if x_0 is a regular singular point

    $x_0 = -1$

- Multiply by denominators

  $4(x^2-1)^2\left(\frac{d^2}{dx^2}y(x)\right) + (-3x^2+6)\,y(x) = 0$

- Change variables using $x = u-1$ so that the regular singular point is at $u=0$

  $(4u^4-16u^3+16u^2)\left(\frac{d^2}{du^2}y(u)\right) + (-3u^2+6u+3)\,y(u) = 0$

- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $u^m\cdot y(u)$ to series expansion for $m=0..2$

    $u^m\cdot y(u) = \sum_{k=0}^{\infty} a_k u^{k+r+m}$

  ◦ Shift index using $k->k-m$

    $u^m\cdot y(u) = \sum_{k=m}^{\infty} a_{k-m} u^{k+r}$

  ◦ Convert $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m=2..4$

$$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, u^{k+r-2+m}$$

- Shift index using $k->k+2-m$

$$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\, u^{k+r}$$

Rewrite ODE with series expansions

$$a_0(-1+4r)(-3+4r)\, u^r + (a_1(3+4r)(1+4r) - 2a_0(8r^2-8r-3))\, u^{1+r} + \left(\sum_{k=2}^{\infty} (a_k(4k+4r-1)\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
$(-1+4r)(-3+4r) = 0$
- Values of r that satisfy the indicial equation
$r \in \left\{\frac{1}{4}, \frac{3}{4}\right\}$
- Each term must be 0
$a_1(3+4r)(1+4r) - 2a_0(8r^2-8r-3) = 0$
- Solve for the dependent coefficient(s)
$a_1 = \frac{2a_0(8r^2-8r-3)}{16r^2+16r+3}$
- Each term in the series must be 0, giving the recursion relation
$4(4a_k + a_{k-2} - 4a_{k-1})\, k^2 + 4(2(4a_k + a_{k-2} - 4a_{k-1})\, r - 4a_k - 5a_{k-2} + 12a_{k-1})\, k + 4(4a_k + a_{k-2} -$
- Shift index using $k->k+2$
$4(4a_{k+2} + a_k - 4a_{k+1})(k+2)^2 + 4(2(4a_{k+2} + a_k - 4a_{k+1})\, r - 4a_{k+2} - 5a_k + 12a_{k+1})(k+2) + 4(4$
- Recursion relation that defines series solution to ODE
$a_{k+2} = -\frac{4k^2a_k - 16k^2a_{k+1} + 8kra_k - 32kra_{k+1} + 4r^2a_k - 16r^2a_{k+1} - 4ka_k - 16ka_{k+1} - 4ra_k - 16ra_{k+1} - 3a_k + 6a_{k+1}}{16k^2+32kr+16r^2+48k+48r+35}$
- Recursion relation for $r = \frac{1}{4}$
$a_{k+2} = -\frac{4k^2a_k - 16k^2a_{k+1} - 2ka_k - 24ka_{k+1} - \frac{15}{4}a_k + a_{k+1}}{16k^2+56k+48}$
- Solution for $r = \frac{1}{4}$
$\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+\frac{1}{4}}, a_{k+2} = -\frac{4k^2a_k - 16k^2a_{k+1} - 2ka_k - 24ka_{k+1} - \frac{15}{4}a_k + a_{k+1}}{16k^2+56k+48}, a_1 = -\frac{9a_0}{8}\right]$
- Revert the change of variables $u = x+1$
$\left[y(x) = \sum_{k=0}^{\infty} a_k(x+1)^{k+\frac{1}{4}}, a_{k+2} = -\frac{4k^2a_k - 16k^2a_{k+1} - 2ka_k - 24ka_{k+1} - \frac{15}{4}a_k + a_{k+1}}{16k^2+56k+48}, a_1 = -\frac{9a_0}{8}\right]$
- Recursion relation for $r = \frac{3}{4}$
$a_{k+2} = -\frac{4k^2a_k - 16k^2a_{k+1} + 2ka_k - 40ka_{k+1} - \frac{15}{4}a_k - 15a_{k+1}}{16k^2+72k+80}$
- Solution for $r = \frac{3}{4}$
$\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+\frac{3}{4}}, a_{k+2} = -\frac{4k^2a_k - 16k^2a_{k+1} + 2ka_k - 40ka_{k+1} - \frac{15}{4}a_k - 15a_{k+1}}{16k^2+72k+80}, a_1 = -\frac{3a_0}{8}\right]$
- Revert the change of variables $u = x+1$
$\left[y(x) = \sum_{k=0}^{\infty} a_k(x+1)^{k+\frac{3}{4}}, a_{k+2} = -\frac{4k^2a_k - 16k^2a_{k+1} + 2ka_k - 40ka_{k+1} - \frac{15}{4}a_k - 15a_{k+1}}{16k^2+72k+80}, a_1 = -\frac{3a_0}{8}\right]$
- Combine solutions and rename parameters
$\left[y(x) = \left(\sum_{k=0}^{\infty} a_k(x+1)^{k+\frac{1}{4}}\right) + \left(\sum_{k=0}^{\infty} b_k(x+1)^{k+\frac{3}{4}}\right), a_{k+2} = -\frac{4k^2a_k - 16k^2a_{k+1} - 2ka_k - 24ka_{k+1} - \frac{15}{4}a_k + a_{k+1}}{16k^2+56k+48},\right.$

2.1.272 Problem 275

Internal problem ID [9444]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 275
Date solved : `Monday, January 27, 2025 at 06:02:54 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$u'' - \frac{2u'}{x} - a^2 u = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.274 (sec)

Writing the ode as

$$u'' - \frac{2u'}{x} - a^2 u = 0 \tag{1}$$
$$Au'' + Bu' + Cu = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -\frac{2}{x} \\ C &= -a^2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = u e^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{a^2x^2 + 2}{x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= a^2x^2 + 2 \\ t &= x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{a^2x^2+2}{x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then u is found using the inverse transformation

$$u = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.518: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{2}{x^2} + a^2$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1 \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx a + \frac{1}{a\,x^2} - \frac{1}{2a^3x^4} + \frac{1}{2a^5x^6} - \frac{5}{8a^7x^8} + \frac{7}{8a^9x^{10}} - \frac{21}{16a^{11}x^{12}} + \frac{33}{16a^{13}x^{14}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = a$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= a \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = a^2$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{a^2x^2 + 2}{x^2} \\ &= Q + \frac{R}{x^2} \\ &= (a^2) + \left(\frac{2}{x^2}\right) \\ &= \frac{2}{x^2} + a^2 \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is 0. Dividing this by leading coefficient in t which is 1 gives 0. Now b can be found.

$$\begin{aligned} b &= (0) - (0) \\ &= 0 \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= a \\ \alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{0}{a} - 0\right) &= 0 \\ \alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{0}{a} - 0\right) &= 0 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{a^2x^2 + 2}{x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	2	-1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	a	0	0

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 0$ then

$$\begin{aligned} d &= \alpha_\infty^- - (\alpha_{c_1}^-) \\ &= 0 - (-1) \\ &= 1 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= -\frac{1}{x} + (-)(a) \\ &= -\frac{1}{x} - a \\ &= \frac{-ax-1}{x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(-\frac{1}{x} - a\right)(1) + \left(\left(\frac{1}{x^2}\right) + \left(-\frac{1}{x} - a\right)^2 - \left(\frac{a^2x^2+2}{x^2}\right) \right) &= 0 \\ \frac{2aa_0 - 2}{x} &= 0 \end{aligned}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\left\{ a_0 = \frac{1}{a} \right\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x + \frac{1}{a}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= \left(x + \frac{1}{a}\right) e^{\int (-\frac{1}{x} - a) dx} \\ &= \left(x + \frac{1}{a}\right) e^{-ax - \ln(x)} \\ &= \frac{(ax+1)\, e^{-ax}}{ax} \end{aligned}$$

The first solution to the original ode in u is found from

$$\begin{aligned} u_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2} \frac{-\frac{2}{x}}{1} \, dx} \\ &= z_1 e^{\ln(x)} \\ &= z_1(x) \end{aligned}$$

Which simplifies to

$$u_1 = \frac{(ax+1)\, e^{-ax}}{a}$$

The second solution u_2 to the original ode is found using reduction of order

$$u_2 = u_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{u_1^2} \, dx$$

Substituting gives

$$\begin{aligned} u_2 &= u_1 \int \frac{e^{\int -\frac{-\frac{2}{x}}{1} \, dx}}{(u_1)^2} \, dx \\ &= u_1 \int \frac{e^{2\ln(x)}}{(u_1)^2} \, dx \\ &= u_1 \left(\frac{(ax-1)\, e^{2ax}}{2a(ax+1)}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} u &= c_1 u_1 + c_2 u_2 \\ &= c_1 \left(\frac{(ax+1)\, e^{-ax}}{a}\right) + c_2 \left(\frac{(ax+1)\, e^{-ax}}{a} \left(\frac{(ax-1)\, e^{2ax}}{2a(ax+1)}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$\frac{d^2}{dx^2}u(x) - \frac{2\left(\frac{d}{dx}u(x)\right)}{x} - a^2u(x) = 0$

2.1.273 Problem 276

Internal problem ID [9445]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 276
Date solved : Monday, January 27, 2025 at 06:02:54 PM
CAS classification : [[_2nd_order, _with_linear_symmetries]]

Solve

$$u'' + \frac{2u'}{x} - a^2 u = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.103 (sec)

Writing the ode as

$$u'' + \frac{2u'}{x} - a^2 u = 0 \tag{1}$$

$$Au'' + Bu' + Cu = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= \frac{2}{x} \\ C &= -a^2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = u e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{a^2}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= a^2 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(a^2\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then u is found using the inverse transformation

$$u = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.520: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = a^2$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = e^{\sqrt{a^2}\, x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in u is found from

$$\begin{aligned} u_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{\frac{2}{x}}{1}\, dx} \\ &= z_1 e^{-\ln(x)} \\ &= z_1\left(\frac{1}{x}\right) \end{aligned}$$

Which simplifies to

$$u_1 = \frac{e^{\operatorname{csgn}(a) a x}}{x}$$

The second solution u_2 to the original ode is found using reduction of order

$$u_2 = u_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{u_1^2}\, dx$$

Substituting gives

$$\begin{aligned} u_2 &= u_1 \int \frac{e^{\int -\frac{\frac{2}{x}}{1}\, dx}}{(u_1)^2}\, dx \\ &= u_1 \int \frac{e^{-2\ln(x)}}{(u_1)^2}\, dx \\ &= u_1 \left(-\frac{\mathrm{e}^{-2\,\mathrm{csgn}(a)ax}}{2\,\mathrm{csgn}\,(a)\,a}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} u &= c_1 u_1 + c_2 u_2 \\ &= c_1 \left(\frac{\mathrm{e}^{\mathrm{csgn}(a)ax}}{x}\right) + c_2 \left(\frac{\mathrm{e}^{\mathrm{csgn}(a)ax}}{x}\left(-\frac{\mathrm{e}^{-2\,\mathrm{csgn}(a)ax}}{2\,\mathrm{csgn}\,(a)\,a}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$\frac{d^2}{dx^2}u(x) + \frac{2\left(\frac{d}{dx}u(x)\right)}{x} - a^2 u(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}u(x)$

□ Check to see if $x_0 = 0$ is a regular singular point

  ○ Define functions

    $\left[P_2(x) = \frac{2}{x}, P_3(x) = -a^2\right]$

  ○ $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left.(x \cdot P_2(x))\right|_{x=0} = 2$

  ○ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $\left.(x^2 \cdot P_3(x))\right|_{x=0} = 0$

  ○ $x = 0$is a regular singular point

    Check to see if $x_0 = 0$ is a regular singular point

    $x_0 = 0$

- Multiply by denominators

  $-a^2 u(x)\, x + \left(\frac{d^2}{dx^2}u(x)\right) x + 2\frac{d}{dx}u(x) = 0$

- Assume series solution for $u(x)$

  $u(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

  ○ Convert $x \cdot u(x)$ to series expansion

    $x \cdot u(x) = \sum_{k=0}^{\infty} a_k x^{k+r+1}$

  ○ Shift index using $k- >k-1$

$x \cdot u(x) = \sum_{k=1}^{\infty} a_{k-1} x^{k+r}$

- Convert $\frac{d}{dx}u(x)$ to series expansion

  $\frac{d}{dx}u(x) = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r-1}$
- Shift index using $k->k+1$

  $\frac{d}{dx}u(x) = \sum_{k=-1}^{\infty} a_{k+1}(k+r+1)\, x^{k+r}$
- Convert $x \cdot \left(\frac{d^2}{dx^2}u(x)\right)$ to series expansion

  $x \cdot \left(\frac{d^2}{dx^2}u(x)\right) = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r-1}$
- Shift index using $k->k+1$

  $x \cdot \left(\frac{d^2}{dx^2}u(x)\right) = \sum_{k=-1}^{\infty} a_{k+1}(k+r+1)\,(k+r)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0 r(1+r)\, x^{-1+r} + a_1(1+r)\,(2+r)\, x^r + \left(\sum_{k=1}^{\infty} \left(a_{k+1}(k+r+1)\,(k+2+r) - a^2 a_{k-1}\right) x^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r(1+r) = 0$
- Values of r that satisfy the indicial equation

  $r \in \{-1, 0\}$
- Each term must be 0

  $a_1(1+r)\,(2+r) = 0$
- Each term in the series must be 0, giving the recursion relation

  $a_{k+1}(k+r+1)\,(k+2+r) - a^2 a_{k-1} = 0$
- Shift index using $k->k+1$

  $a_{k+2}(k+2+r)\,(k+3+r) - a^2 a_k = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+2} = \frac{a^2 a_k}{(k+2+r)(k+3+r)}$
- Recursion relation for $r = -1$

  $a_{k+2} = \frac{a^2 a_k}{(k+1)(k+2)}$
- Solution for $r = -1$

  $\left[u(x) = \sum_{k=0}^{\infty} a_k x^{k-1}, a_{k+2} = \frac{a^2 a_k}{(k+1)(k+2)}, 0 = 0\right]$
- Recursion relation for $r = 0$

  $a_{k+2} = \frac{a^2 a_k}{(k+2)(k+3)}$
- Solution for $r = 0$

  $\left[u(x) = \sum_{k=0}^{\infty} a_k x^k, a_{k+2} = \frac{a^2 a_k}{(k+2)(k+3)}, 2a_1 = 0\right]$
- Combine solutions and rename parameters

  $\left[u(x) = \left(\sum_{k=0}^{\infty} b_k x^{k-1}\right) + \left(\sum_{k=0}^{\infty} c_k x^k\right), b_{k+2} = \frac{a^2 b_k}{(k+1)(k+2)}, 0 = 0, c_{k+2} = \frac{a^2 c_k}{(k+2)(k+3)}, 2c_1 = 0\right]$

2.1.274 Problem 277

Internal problem ID [9446]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 277
Date solved : `Monday, January 27, 2025 at 06:02:55 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$u'' + \frac{2u'}{x} + a^2 u = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.118 (sec)

Writing the ode as

$$u'' + \frac{2u'}{x} + a^2 u = 0 \tag{1}$$
$$Au'' + Bu' + Cu = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= \frac{2}{x} \\ C &= a^2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = u e^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-a^2}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -a^2 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(-a^2\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then u is found using the inverse transformation

$$u = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.522: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -a^2$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{\sqrt{-a^2}\, x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in u is found from

$$\begin{aligned} u_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{\frac{2}{x}}{1}\, dx} \\ &= z_1 e^{-\ln(x)} \\ &= z_1 \left(\frac{1}{x}\right) \end{aligned}$$

Which simplifies to

$$u_1 = \frac{\mathrm{e}^{\sqrt{-a^2}\, x}}{x}$$

The second solution u_2 to the original ode is found using reduction of order

$$u_2 = u_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{u_1^2}\, dx$$

Substituting gives

$$\begin{aligned} u_2 &= u_1 \int \frac{e^{\int -\frac{\frac{2}{x}}{1}\, dx}}{(u_1)^2}\, dx \\ &= u_1 \int \frac{e^{-2\ln(x)}}{(u_1)^2}\, dx \\ &= u_1 \left(\frac{\sqrt{-a^2}\, \mathrm{e}^{-2\sqrt{-a^2}\, x}}{2a^2}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} u &= c_1 u_1 + c_2 u_2 \\ &= c_1 \left(\frac{\mathrm{e}^{\sqrt{-a^2}\, x}}{x}\right) + c_2 \left(\frac{\mathrm{e}^{\sqrt{-a^2}\, x}}{x} \left(\frac{\sqrt{-a^2}\, \mathrm{e}^{-2\sqrt{-a^2}\, x}}{2a^2}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

2.1.275 Problem 278

Internal problem ID [9447]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 278
Date solved : `Monday, January 27, 2025 at 06:02:55 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$u'' + \frac{4u'}{x} - a^2 u = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.269 (sec)

Writing the ode as

$$u'' + \frac{4u'}{x} - a^2 u = 0 \tag{1}$$

$$Au'' + Bu' + Cu = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= \frac{4}{x} \\ C &= -a^2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = u e^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{a^2 x^2 + 2}{x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= a^2 x^2 + 2 \\ t &= x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{a^2x^2+2}{x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then u is found using the inverse transformation

$$u = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.524: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2-2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1,2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{2}{x^2} + a^2$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1 \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\
&= \sum_{i=0}^{0} a_i x^i
\end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx a + \frac{1}{a\,x^2} - \frac{1}{2a^3x^4} + \frac{1}{2a^5x^6} - \frac{5}{8a^7x^8} + \frac{7}{8a^9x^{10}} - \frac{21}{16a^{11}x^{12}} + \frac{33}{16a^{13}x^{14}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = a$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\
&= a
\end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = a^2$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{a^2x^2 + 2}{x^2} \\
&= Q + \frac{R}{x^2} \\
&= (a^2) + \left(\frac{2}{x^2}\right) \\
&= \frac{2}{x^2} + a^2
\end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is 0. Dividing this by leading coefficient in t which is 1 gives 0. Now b can be found.

$$\begin{aligned}
b &= (0) - (0) \\
&= 0
\end{aligned}$$

Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= a \\
\alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{0}{a} - 0\right) &&= 0 \\
\alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{0}{a} - 0\right) &&= 0
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{a^2x^2 + 2}{x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	2	-1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	a	0	0

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 0$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\ &= 0 - (-1) \\ &= 1 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x - c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= -\frac{1}{x} + (-)(a) \\ &= -\frac{1}{x} - a \\ &= \frac{-ax - 1}{x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{x} - a\right)(1) + \left(\left(\frac{1}{x^2}\right) + \left(-\frac{1}{x} - a\right)^2 - \left(\frac{a^2x^2 + 2}{x^2}\right)\right) = 0$$

$$\frac{2aa_0 - 2}{x} = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\left\{a_0 = \frac{1}{a}\right\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x + \frac{1}{a}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \left(x + \frac{1}{a}\right) e^{\int \left(-\frac{1}{x} - a\right) dx} \\
&= \left(x + \frac{1}{a}\right) e^{-ax - \ln(x)} \\
&= \frac{(ax + 1) e^{-ax}}{ax}
\end{aligned}$$

The first solution to the original ode in u is found from

$$\begin{aligned}
u_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{\frac{4}{x}}{1} \, dx} \\
&= z_1 e^{-2\ln(x)} \\
&= z_1 \left(\frac{1}{x^2}\right)
\end{aligned}$$

Which simplifies to

$$u_1 = \frac{(ax + 1) e^{-ax}}{x^3 a}$$

The second solution u_2 to the original ode is found using reduction of order

$$u_2 = u_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{u_1^2} \, dx$$

Substituting gives

$$\begin{aligned}
u_2 &= u_1 \int \frac{e^{\int -\frac{\frac{4}{x}}{1} \, dx}}{(u_1)^2} \, dx \\
&= u_1 \int \frac{e^{-4\ln(x)}}{(u_1)^2} \, dx \\
&= u_1 \left(\frac{(ax - 1) e^{2ax}}{2a(ax + 1)}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
u &= c_1 u_1 + c_2 u_2 \\
&= c_1 \left(\frac{(ax + 1) e^{-ax}}{x^3 a}\right) + c_2 \left(\frac{(ax + 1) e^{-ax}}{x^3 a} \left(\frac{(ax - 1) e^{2ax}}{2a(ax + 1)}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$\frac{d^2}{dx^2}u(x) + \frac{4\left(\frac{d}{dx}u(x)\right)}{x} - a^2u(x) = 0$

- Highest derivative means the order of the ODE is 2

2.1.276 Problem 279

Internal problem ID [9448]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 279
Date solved : `Monday, January 27, 2025 at 06:02:56 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$u'' + \frac{4u'}{x} + a^2 u = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.316 (sec)

Writing the ode as

$$u'' + \frac{4u'}{x} + a^2 u = 0 \tag{1}$$

$$Au'' + Bu' + Cu = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= \frac{4}{x} \\ C &= a^2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = u e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-a^2x^2 + 2}{x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -a^2x^2 + 2 \\ t &= x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{-a^2x^2+2}{x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then u is found using the inverse transformation

$$u = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.526: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{2}{x^2} - a^2$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1 \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx ia - \frac{i}{a\,x^2} - \frac{i}{2a^3x^4} - \frac{i}{2a^5x^6} - \frac{5i}{8a^7x^8} - \frac{7i}{8a^9x^{10}} - \frac{21i}{16a^{11}x^{12}} - \frac{33i}{16a^{13}x^{14}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = ia$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= ia \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = -a^2$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{-a^2x^2 + 2}{x^2} \\ &= Q + \frac{R}{x^2} \\ &= (-a^2) + \left(\frac{2}{x^2}\right) \\ &= \frac{2}{x^2} - a^2 \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is 0. Dividing this by leading coefficient in t which is 1 gives 0. Now b can be found.

$$\begin{aligned} b &= (0) - (0) \\ &= 0 \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= ia \\ \alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{0}{ia} - 0\right) &= 0 \\ \alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{0}{ia} - 0\right) &= 0 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{-a^2x^2 + 2}{x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	2	-1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	ia	0	0

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 0$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\ &= 0 - (-1) \\ &= 1 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= -\frac{1}{x} + (-)\,(ia) \\ &= -\frac{1}{x} - ia \\ &= -\frac{1}{x} - ia \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{x} - ia\right)(1) + \left(\left(\frac{1}{x^2}\right) + \left(-\frac{1}{x} - ia\right)^2 - \left(\frac{-a^2x^2+2}{x^2}\right)\right) = 0$$

$$\frac{2iaa_0 - 2}{x} = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\left\{a_0 = -\frac{i}{a}\right\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x - \frac{i}{a}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \left(x - \frac{i}{a}\right) e^{\int \left(-\frac{1}{x} - ia\right) dx} \\
&= \left(x - \frac{i}{a}\right) e^{-\ln(x) - iax} \\
&= \frac{(ax - i)\, e^{-iax}}{xa}
\end{aligned}$$

The first solution to the original ode in u is found from

$$\begin{aligned}
u_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{\frac{4}{x}}{1} \, dx} \\
&= z_1 e^{-2\ln(x)} \\
&= z_1 \left(\frac{1}{x^2}\right)
\end{aligned}$$

Which simplifies to

$$u_1 = \frac{(ax - i)\, e^{-iax}}{x^3 a}$$

The second solution u_2 to the original ode is found using reduction of order

$$u_2 = u_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{u_1^2} \, dx$$

Substituting gives

$$\begin{aligned}
u_2 &= u_1 \int \frac{e^{\int -\frac{\frac{4}{x}}{1} \, dx}}{(u_1)^2} \, dx \\
&= u_1 \int \frac{e^{-4\ln(x)}}{(u_1)^2} \, dx \\
&= u_1 \left(\frac{(iax - 1)\, e^{2iax}}{2a\,(-ax + i)}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
u &= c_1 u_1 + c_2 u_2 \\
&= c_1 \left(\frac{(ax - i)\, e^{-iax}}{x^3 a}\right) + c_2 \left(\frac{(ax - i)\, e^{-iax}}{x^3 a} \left(\frac{(iax - 1)\, e^{2iax}}{2a\,(-ax + i)}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$\frac{d^2}{dx^2}u(x) + \frac{4\left(\frac{d}{dx}u(x)\right)}{x} + a^2u(x) = 0$

    $x \cdot u(x) = \sum_{k=0}^{\infty} a_k x^{k+r+1}$
  - Shift index using $k- >k-1$

    $x \cdot u(x) = \sum_{k=1}^{\infty} a_{k-1} x^{k+r}$
  - Convert $\frac{d}{dx}u(x)$ to series expansion

    $\frac{d}{dx}u(x) = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1}$
  - Shift index using $k- >k+1$

    $\frac{d}{dx}u(x) = \sum_{k=-1}^{\infty} a_{k+1}(k+r+1)\,x^{k+r}$
  - Convert $x \cdot \left(\frac{d^2}{dx^2}u(x)\right)$ to series expansion

    $x \cdot \left(\frac{d^2}{dx^2}u(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r-1}$
  - Shift index using $k- >k+1$

    $x \cdot \left(\frac{d^2}{dx^2}u(x)\right) = \sum_{k=-1}^{\infty} a_{k+1}(k+r+1)\,(k+r)\,x^{k+r}$

  Rewrite ODE with series expansions

  $a_0r(3+r)\,x^{-1+r} + a_1(1+r)\,(4+r)\,x^r + \left(\sum_{k=1}^{\infty}\left(a_{k+1}(k+r+1)\,(k+4+r) + a^2a_{k-1}\right)x^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r(3+r) = 0$

- Values of r that satisfy the indicial equation

$r \in \{-3, 0\}$

- Each term must be 0

  $a_1(1+r)(4+r) = 0$

- Each term in the series must be 0, giving the recursion relation

  $a_{k+1}(k+r+1)(k+4+r) + a^2 a_{k-1} = 0$

- Shift index using $k- >k+1$

  $a_{k+2}(k+2+r)(k+5+r) + a^2 a_k = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{a^2 a_k}{(k+2+r)(k+5+r)}$

- Recursion relation for $r = -3$

  $a_{k+2} = -\frac{a^2 a_k}{(k-1)(k+2)}$

- Solution for $r = -3$

  $\left[u(x) = \sum_{k=0}^{\infty} a_k x^{k-3}, a_{k+2} = -\frac{a^2 a_k}{(k-1)(k+2)}, -2a_1 = 0\right]$

- Recursion relation for $r = 0$

  $a_{k+2} = -\frac{a^2 a_k}{(k+2)(k+5)}$

- Solution for $r = 0$

  $\left[u(x) = \sum_{k=0}^{\infty} a_k x^k, a_{k+2} = -\frac{a^2 a_k}{(k+2)(k+5)}, 4a_1 = 0\right]$

- Combine solutions and rename parameters

  $\left[u(x) = \left(\sum_{k=0}^{\infty} b_k x^{k-3}\right) + \left(\sum_{k=0}^{\infty} c_k x^k\right), b_{k+2} = -\frac{a^2 b_k}{(k+2)(k-1)}, -2b_1 = 0, c_{k+2} = -\frac{a^2 c_k}{(5+k)(k+2)}, 4c_1 = 0\right]$

2.1.277 Problem 280

Internal problem ID [9449]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 280
Date solved : Monday, January 27, 2025 at 06:02:57 PM
CAS classification : [[_2nd_order, _with_linear_symmetries]]

Solve

$$y'' - a^2 y = \frac{6y}{x^2}$$

Solved as second order ode using Kovacic algorithm

Time used: 0.284 (sec)

Writing the ode as

$$y'' + \left(-a^2 - \frac{6}{x^2}\right) y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= -a^2 - \frac{6}{x^2} \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{a^2 x^2 + 6}{x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= a^2 x^2 + 6 \\ t &= x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{a^2x^2+6}{x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.528: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = a^2 + \frac{6}{x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = 6$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 3 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -2 \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx a + \frac{3}{a\,x^2} - \frac{9}{2a^3x^4} + \frac{27}{2a^5x^6} - \frac{405}{8a^7x^8} + \frac{1701}{8a^9x^{10}} - \frac{15309}{16a^{11}x^{12}} + \frac{72171}{16a^{13}x^{14}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = a$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= a \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = a^2$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{a^2x^2 + 6}{x^2} \\ &= Q + \frac{R}{x^2} \\ &= (a^2) + \left(\frac{6}{x^2}\right) \\ &= a^2 + \frac{6}{x^2} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is 0. Dividing this by leading coefficient in t which is 1 gives 0. Now b can be found.

$$\begin{aligned} b &= (0) - (0) \\ &= 0 \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= a \\ \alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) = \frac{1}{2}\left(\frac{0}{a} - 0\right) = 0 \\ \alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) = \frac{1}{2}\left(-\frac{0}{a} - 0\right) = 0 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{a^2x^2+6}{x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	3	-2

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	a	0	0

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 0$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\ &= 0 - (-2) \\ &= 2 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= -\frac{2}{x} + (-)(a) \\ &= -\frac{2}{x} - a \\ &= \frac{-ax-2}{x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 2$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x^2 + a_1 x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(2) + 2\left(-\frac{2}{x} - a\right)(2x + a_1) + \left(\left(\frac{2}{x^2}\right) + \left(-\frac{2}{x} - a\right)^2 - \left(\frac{a^2x^2+6}{x^2}\right) \right) = 0$$

$$\frac{2axa_1 + 4aa_0 - 6x - 4a_1}{x} = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\left\{ a_0 = \frac{3}{a^2}, a_1 = \frac{3}{a} \right\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^2 + \frac{3x}{a} + \frac{3}{a^2}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega\, dx} \\ &= \left(x^2 + \frac{3x}{a} + \frac{3}{a^2}\right) e^{\int \left(-\frac{2}{x} - a\right) dx} \\ &= \left(x^2 + \frac{3x}{a} + \frac{3}{a^2}\right) e^{-ax - 2\ln(x)} \\ &= \frac{(a^2x^2 + 3ax + 3)\, e^{-ax}}{a^2x^2} \end{aligned}$$

The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \frac{(a^2x^2 + 3ax + 3)\, e^{-ax}}{a^2x^2} \end{aligned}$$

Which simplifies to

$$y_1 = \frac{(a^2x^2 + 3ax + 3)\, e^{-ax}}{a^2x^2}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\ &= \frac{(a^2x^2 + 3ax + 3)\, e^{-ax}}{a^2x^2} \int \frac{1}{\frac{(a^2x^2+3ax+3)^2 e^{-2ax}}{a^4x^4}}\, dx \\ &= \frac{(a^2x^2 + 3ax + 3)\, e^{-ax}}{a^2x^2} \left(\frac{(a^2x^2 - 3ax + 3)\, e^{2ax}}{2a\,(a^2x^2 + 3ax + 3)}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\frac{(a^2x^2 + 3ax + 3)\, e^{-ax}}{a^2x^2}\right) + c_2 \left(\frac{(a^2x^2 + 3ax + 3)\, e^{-ax}}{a^2x^2} \left(\frac{(a^2x^2 - 3ax + 3)\, e^{2ax}}{2a\,(a^2x^2 + 3ax + 3)}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$\frac{d^2}{dx^2}y(x) - a^2y(x) = \frac{6y(x)}{x^2}$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = \frac{(a^2x^2+6)y(x)}{x^2}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lir

  $\frac{d^2}{dx^2}y(x) - \frac{(a^2x^2+6)y(x)}{x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

- ◦ Define functions

  $\left[P_2(x) = 0, P_3(x) = -\frac{a^2x^2+6}{x^2}\right]$

- ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

  $(x \cdot P_2(x))\Big|_{x=0} = 0$

- ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $(x^2 \cdot P_3(x))\Big|_{x=0} = -6$

- ◦ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $x^2\left(\frac{d^2}{dx^2}y(x)\right) + (-a^2x^2 - 6)\,y(x) = 0$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

- ◦ Convert $x^m \cdot y(x)$ to series expansion for $m = 0..2$

  $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- ◦ Shift index using $k- >k - m$

  $x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- ◦ Convert $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

  $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(2+r)\,(-3+r)\,x^r + a_1(3+r)\,(-2+r)\,x^{1+r} + \left(\sum_{k=2}^{\infty} (a_k(k+r+2)\,(k+r-3) - a_{k-2}a^2)\,x^{k+r}\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(2+r)\,(-3+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{-2, 3\}$

- Each term must be 0

  $a_1(3+r)\,(-2+r) = 0$

- Solve for the dependent coefficient(s)

  $a_1 = 0$

- Each term in the series must be 0, giving the recursion relation

  $a_k(k+r+2)(k+r-3) - a_{k-2}a^2 = 0$
- Shift index using $k- >k+2$

  $a_{k+2}(k+4+r)(k+r-1) - a_k a^2 = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+2} = \frac{a_k a^2}{(k+4+r)(k+r-1)}$
- Recursion relation for $r = -2$

  $a_{k+2} = \frac{a_k a^2}{(k+2)(k-3)}$
- Solution for $r = -2$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k-2}, a_{k+2} = \frac{a_k a^2}{(k+2)(k-3)}, a_1 = 0\right]$
- Recursion relation for $r = 3$

  $a_{k+2} = \frac{a_k a^2}{(k+7)(k+2)}$
- Solution for $r = 3$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+3}, a_{k+2} = \frac{a_k a^2}{(k+7)(k+2)}, a_1 = 0\right]$
- Combine solutions and rename parameters

  $\left[y(x) = \left(\sum_{k=0}^{\infty} b_k x^{k-2}\right) + \left(\sum_{k=0}^{\infty} c_k x^{k+3}\right), b_{k+2} = \frac{b_k a^2}{(k+2)(k-3)}, b_1 = 0, c_{k+2} = \frac{c_k a^2}{(k+7)(k+2)}, c_1 = 0\right]$

2.1.278 Problem 281

Internal problem ID [9450]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 281
Date solved : `Monday, January 27, 2025 at 06:02:57 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$y'' + n^2 y = \frac{6y}{x^2}$$

Solved as second order ode using Kovacic algorithm

Time used: 0.336 (sec)

Writing the ode as

$$y'' + \left(n^2 - \frac{6}{x^2}\right) y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= n^2 - \frac{6}{x^2} \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-n^2 x^2 + 6}{x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -n^2 x^2 + 6 \\ t &= x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{-n^2x^2+6}{x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.530: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2-2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1,2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -n^2 + \frac{6}{x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = 6$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 3 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -2 \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx in - \frac{3i}{n\,x^2} - \frac{9i}{2n^3x^4} - \frac{27i}{2n^5x^6} - \frac{405i}{8n^7x^8} - \frac{1701i}{8n^9x^{10}} - \frac{15309i}{16n^{11}x^{12}} - \frac{72171i}{16n^{13}x^{14}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = in$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= in \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = -n^2$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{-n^2x^2 + 6}{x^2} \\ &= Q + \frac{R}{x^2} \\ &= (-n^2) + \left(\frac{6}{x^2}\right) \\ &= -n^2 + \frac{6}{x^2} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is 0. Dividing this by leading coefficient in t which is 1 gives 0. Now b can be found.

$$\begin{aligned} b &= (0) - (0) \\ &= 0 \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= in \\ \alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) = \frac{1}{2}\left(\frac{0}{in} - 0\right) = 0 \\ \alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) = \frac{1}{2}\left(-\frac{0}{in} - 0\right) = 0 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r=\frac{-n^2x^2+6}{x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	3	-2

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	in	0	0

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^-=0$ then

$$\begin{aligned}d&=\alpha_\infty^--\left(\alpha_{c_1}^-\right)\\&=0-(-2)\\&=2\end{aligned}$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$\omega=\sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c+\frac{\alpha_c^{s(c)}}{x-c}\right)+s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}\omega&=\left((-)[\sqrt{r}]_{c_1}+\frac{\alpha_{c_1}^-}{x-c_1}\right)+(-)[\sqrt{r}]_\infty\\&=-\frac{2}{x}+(-)\,(in)\\&=-\frac{2}{x}-in\\&=-\frac{2}{x}-in\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=2$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p''+2\omega p'+\left(\omega'+\omega^2-r\right)p=0 \tag{1A}$$

Let

$$p(x)=x^2+a_1x+a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(2)+2\left(-\frac{2}{x}-in\right)(2x+a_1)+\left(\left(\frac{2}{x^2}\right)+\left(-\frac{2}{x}-in\right)^2-\left(\frac{-n^2x^2+6}{x^2}\right)\right)=0$$

$$\frac{(2ina_1-6)\,x+4ina_0-4a_1}{x}=0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\left\{a_0=-\frac{3}{n^2},a_1=-\frac{3i}{n}\right\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^2 - \frac{3ix}{n} - \frac{3}{n^2}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \left(x^2 - \frac{3ix}{n} - \frac{3}{n^2}\right) e^{\int \left(-\frac{2}{x} - in\right) dx} \\
&= \left(x^2 - \frac{3ix}{n} - \frac{3}{n^2}\right) e^{-2\ln(x) - inx} \\
&= \frac{(n^2x^2 - 3inx - 3)\, e^{-inx}}{x^2n^2}
\end{aligned}$$

The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned}
y_1 &= z_1 \\
&= \frac{(n^2x^2 - 3inx - 3)\, e^{-inx}}{x^2n^2}
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{(n^2x^2 - 3inx - 3)\, e^{-inx}}{x^2n^2}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned}
y_2 &= y_1 \int \frac{1}{y_1^2} \, dx \\
&= \frac{(n^2x^2 - 3inx - 3)\, e^{-inx}}{x^2n^2} \int \frac{1}{\frac{(n^2x^2 - 3inx - 3)^2 e^{-2inx}}{x^4n^4}} \, dx \\
&= \frac{(n^2x^2 - 3inx - 3)\, e^{-inx}}{x^2n^2} \left(\frac{(in^2x^2 - 3nx - 3i)\, e^{2inx}}{2n\,(-n^2x^2 + 3inx + 3)}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1y_1 + c_2y_2 \\
&= c_1\left(\frac{(n^2x^2 - 3inx - 3)\, e^{-inx}}{x^2n^2}\right) + c_2\left(\frac{(n^2x^2 - 3inx - 3)\, e^{-inx}}{x^2n^2}\left(\frac{(in^2x^2 - 3nx - 3i)\, e^{2inx}}{2n\,(-n^2x^2 + 3inx + 3)}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$\frac{d^2}{dx^2}y(x) + n^2 y(x) = \frac{6y(x)}{x^2}$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{(n^2x^2-6)y(x)}{x^2}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x) + \frac{(n^2x^2-6)y(x)}{x^2} = 0$

☐ Check to see if $x_0 = 0$ is a regular singular point

- ○ Define functions

  $\left[P_2(x) = 0, P_3(x) = \frac{n^2x^2-6}{x^2}\right]$

- ○ $x \cdot P_2(x)$ is analytic at $x = 0$

  $\left(x \cdot P_2(x)\right)\Big|_{x=0} = 0$

- ○ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $\left(x^2 \cdot P_3(x)\right)\Big|_{x=0} = -6$

- ○ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $x^2\left(\frac{d^2}{dx^2}y(x)\right) + (n^2x^2 - 6)\, y(x) = 0$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

- ○ Convert $x^m \cdot y(x)$ to series expansion for $m = 0..2$

  $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- ○ Shift index using $k- >k - m$

  $x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- ○ Convert $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

  $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(2+r)(-3+r)\, x^r + a_1(3+r)(-2+r)\, x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(k+r+2)(k+r-3) + a_{k-2}n^2\right) x^{k+r}\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(2+r)(-3+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{-2, 3\}$

- Each term must be 0

  $a_1(3+r)(-2+r) = 0$

- Solve for the dependent coefficient(s)

  $a_1 = 0$

- Each term in the series must be 0, giving the recursion relation

  $a_k(k+r+2)(k+r-3)+a_{k-2}n^2=0$
- Shift index using $k->k+2$

  $a_{k+2}(k+4+r)(k+r-1)+a_k n^2=0$
- Recursion relation that defines series solution to ODE

  $a_{k+2}=-\frac{a_k n^2}{(k+4+r)(k+r-1)}$
- Recursion relation for $r=-2$

  $a_{k+2}=-\frac{a_k n^2}{(k+2)(k-3)}$
- Solution for $r=-2$

  $\left[y(x)=\sum_{k=0}^{\infty} a_k x^{k-2}, a_{k+2}=-\frac{a_k n^2}{(k+2)(k-3)}, a_1=0\right]$
- Recursion relation for $r=3$

  $a_{k+2}=-\frac{a_k n^2}{(k+7)(k+2)}$
- Solution for $r=3$

  $\left[y(x)=\sum_{k=0}^{\infty} a_k x^{k+3}, a_{k+2}=-\frac{a_k n^2}{(k+7)(k+2)}, a_1=0\right]$
- Combine solutions and rename parameters

  $\left[y(x)=\left(\sum_{k=0}^{\infty} a_k x^{k-2}\right)+\left(\sum_{k=0}^{\infty} b_k x^{k+3}\right), a_{k+2}=-\frac{a_k n^2}{(k+2)(k-3)}, a_1=0, b_{k+2}=-\frac{b_k n^2}{(k+7)(k+2)}, b_1=0\right]$

2.1.279 Problem 282

Internal problem ID [9451]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 282
Date solved : `Monday, January 27, 2025 at 06:02:58 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' + xy' - \left(x^2 + \frac{1}{4}\right) y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.079 (sec)

Writing the ode as

$$x^2y'' + xy' + \left(-x^2 - \frac{1}{4}\right) y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= x \\ C &= -x^2 - \frac{1}{4} \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$s = 1$$
$$t = 1$$

Therefore eq. (4) becomes

$$z''(x) = z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.532: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{x}{x^2}\, dx} \\ &= z_1 e^{-\frac{\ln(x)}{2}} \\ &= z_1 \left(\frac{1}{\sqrt{x}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{\mathrm{e}^{-x}}{\sqrt{x}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}y_2 &= y_1 \int \frac{e^{\int -\frac{x}{x^2}\, dx}}{(y_1)^2}\, dx\\ &= y_1 \int \frac{e^{-\ln(x)}}{(y_1)^2}\, dx\\ &= y_1 \left(\frac{e^{2x}}{2}\right)\end{aligned}$$

Therefore the solution is

$$\begin{aligned}y &= c_1 y_1 + c_2 y_2\\ &= c_1 \left(\frac{e^{-x}}{\sqrt{x}}\right) + c_2 \left(\frac{e^{-x}}{\sqrt{x}}\left(\frac{e^{2x}}{2}\right)\right)\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2\left(\frac{d^2}{dx^2}y(x)\right) + x\left(\frac{d}{dx}y(x)\right) - \left(x^2 + \frac{1}{4}\right) y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = \frac{(4x^2+1)y(x)}{4x^2} - \frac{\frac{d}{dx}y(x)}{x}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x) + \frac{\frac{d}{dx}y(x)}{x} - \frac{(4x^2+1)y(x)}{4x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  - Define functions

    $\left[P_2(x) = \frac{1}{x}, P_3(x) = -\frac{4x^2+1}{4x^2}\right]$

  - $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left.(x \cdot P_2(x))\right|_{x=0} = 1$

  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $\left.(x^2 \cdot P_3(x))\right|_{x=0} = -\frac{1}{4}$

  - $x = 0$is a regular singular point

    Check to see if $x_0 = 0$ is a regular singular point

    $x_0 = 0$

- Multiply by denominators

  $4x^2\left(\frac{d^2}{dx^2}y(x)\right) + 4x\left(\frac{d}{dx}y(x)\right) + (-4x^2 - 1)\, y(x) = 0$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $x^m \cdot y(x)$ to series expansion for $m = 0..2$

  $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- Shift index using $k- >k - m$

  $x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- Convert $x \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion

  $x \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r}$

- Convert $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

  $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(1+2r)\,(-1+2r)\, x^r + a_1(3+2r)\,(1+2r)\, x^{1+r} + \left(\sum_{k=2}^{\infty} (a_k(2k+2r+1)\,(2k+2r-1) - 4a_{k-}\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(1+2r)\,(-1+2r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \left\{-\frac{1}{2}, \frac{1}{2}\right\}$

- Each term must be 0

  $a_1(3+2r)\,(1+2r) = 0$

- Solve for the dependent coefficient(s)

  $a_1 = 0$

- Each term in the series must be 0, giving the recursion relation

  $a_k(4k^2 + 8kr + 4r^2 - 1) - 4a_{k-2} = 0$

- Shift index using $k- >k + 2$

  $a_{k+2}\left(4(k+2)^2 + 8(k+2)\,r + 4r^2 - 1\right) - 4a_k = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+2} = \frac{4a_k}{4k^2+8kr+4r^2+16k+16r+15}$

- Recursion relation for $r = -\frac{1}{2}$

  $a_{k+2} = \frac{4a_k}{4k^2+12k+8}$

- Solution for $r = -\frac{1}{2}$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k-\frac{1}{2}}, a_{k+2} = \frac{4a_k}{4k^2+12k+8}, a_1 = 0\right]$

- Recursion relation for $r = \frac{1}{2}$

  $a_{k+2} = \frac{4a_k}{4k^2+20k+24}$

- Solution for $r = \frac{1}{2}$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}, a_{k+2} = \frac{4a_k}{4k^2+20k+24}, a_1 = 0\right]$

- Combine solutions and rename parameters

  $\left[y(x) = \left(\sum_{k=0}^{\infty} a_k x^{k-\frac{1}{2}}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{2}}\right), a_{k+2} = \frac{4a_k}{4k^2+12k+8}, a_1 = 0, b_{k+2} = \frac{4b_k}{4k^2+20k+24}, b_1 = 0\right]$

Solve

$$x^2y'' + xy' + \frac{(-9a^2 + 4x^2)\, y}{4a^2} = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.303 (sec)

Writing the ode as

$$x^2y'' + xy' + \left(-\frac{9}{4} + \frac{x^2}{a^2}\right) y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= x \\ C &= -\frac{9}{4} + \frac{x^2}{a^2} \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{2a^2 - x^2}{x^2a^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 2a^2 - x^2 \\ t &= x^2a^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{2a^2 - x^2}{x^2 a^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.534: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = x^2 a^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{a^2} + \frac{2}{x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -1 \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx -\frac{33ia^{13}}{16x^{14}} - \frac{21ia^{11}}{16x^{12}} - \frac{7ia^9}{8x^{10}} - \frac{5ia^7}{8x^8} - \frac{ia^5}{2x^6} - \frac{ia^3}{2x^4} - \frac{ia}{x^2} + \frac{i}{a} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{i}{a}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{i}{a} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = -\frac{1}{a^2}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2a^2 - x^2}{x^2 a^2} \\ &= Q + \frac{R}{x^2 a^2} \\ &= \left(-\frac{1}{a^2}\right) + \left(\frac{2}{x^2}\right) \\ &= -\frac{1}{a^2} + \frac{2}{x^2} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is 0. Dividing this by leading coefficient in t which is 1 gives 0. Now b can be found.

$$\begin{aligned} b &= (0) - (0) \\ &= 0 \end{aligned}$$

Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= \frac{i}{a} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{0}{\frac{i}{a}} - 0\right) &&= 0 \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{0}{\frac{i}{a}} - 0\right) &&= 0 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{2a^2 - x^2}{x^2 a^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	2	-1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{i}{a}$	0	0

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 0$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\ &= 0 - (-1) \\ &= 1 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= -\frac{1}{x} + (-)\left(\frac{i}{a}\right) \\ &= -\frac{1}{x} - \frac{i}{a} \\ &= -\frac{ix+a}{xa} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{x} - \frac{i}{a}\right)(1) + \left(\left(\frac{1}{x^2}\right) + \left(-\frac{1}{x} - \frac{i}{a}\right)^2 - \left(\frac{2a^2 - x^2}{x^2 a^2}\right)\right) = 0$$

$$\frac{2ia_0 - 2a}{xa} = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = -ia\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = -ia + x$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= (-ia + x) \, \mathrm{e}^{\int \left(-\frac{1}{x} - \frac{i}{a}\right) dx} \\ &= (-ia + x) \, \mathrm{e}^{-\ln(x) - \frac{ix}{a}} \\ &= \frac{(-ia + x) \, \mathrm{e}^{-\frac{ix}{a}}}{x} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2} \frac{x}{x^2} \, dx} \\ &= z_1 e^{-\frac{\ln(x)}{2}} \\ &= z_1 \left(\frac{1}{\sqrt{x}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{(-ia + x) \, \mathrm{e}^{-\frac{ix}{a}}}{x^{3/2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{x}{x^2} \, dx}}{(y_1)^2} \, dx \\ &= y_1 \int \frac{e^{-\ln(x)}}{(y_1)^2} \, dx \\ &= y_1 \left(-\frac{(ix + a) \, a (ia + x) \, \mathrm{e}^{\frac{2ix}{a}}}{2 \, (ia - x)^2}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\frac{(-ia + x) \, \mathrm{e}^{-\frac{ix}{a}}}{x^{3/2}}\right) + c_2 \left(\frac{(-ia + x) \, \mathrm{e}^{-\frac{ix}{a}}}{x^{3/2}} \left(-\frac{(ix + a) \, a (ia + x) \, \mathrm{e}^{\frac{2ix}{a}}}{2 \, (ia - x)^2}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2\left(\frac{d^2}{dx^2}y(x)\right)+x\left(\frac{d}{dx}y(x)\right)+\frac{(-9a^2+4x^2)y(x)}{4a^2}=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x)=\frac{(9a^2-4x^2)y(x)}{4a^2x^2}-\frac{\frac{d}{dx}y(x)}{x}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x)+\frac{\frac{d}{dx}y(x)}{x}-\frac{(9a^2-4x^2)y(x)}{4a^2x^2}=0$

- Multiply by denominators of the ODE

  $4\left(\frac{d^2}{dx^2}y(x)\right)x^2a^2+4\left(\frac{d}{dx}y(x)\right)x\,a^2-(9a^2-4x^2)\,y(x)=0$

- Make a change of variables

  $t=\ln(x)$

- ☐ Substitute the change of variables back into the ODE
  - ○ Calculate the 1st derivative of y with respect to x , using the chain rule

    $\frac{d}{dx}y(x)=\left(\frac{d}{dt}y(t)\right)\left(\frac{d}{dx}t(x)\right)$

  - ○ Compute derivative

    $\frac{d}{dx}y(x)=\frac{\frac{d}{dt}y(t)}{x}$

  - ○ Calculate the 2nd derivative of y with respect to x , using the chain rule

    $\frac{d^2}{dx^2}y(x)=\left(\frac{d^2}{dt^2}y(t)\right)\left(\frac{d}{dx}t(x)\right)^2+\left(\frac{d^2}{dx^2}t(x)\right)\left(\frac{d}{dt}y(t)\right)$

  - ○ Compute derivative

    $\frac{d^2}{dx^2}y(x)=\frac{\frac{d^2}{dt^2}y(t)}{x^2}-\frac{\frac{d}{dt}y(t)}{x^2}$

  Substitute the change of variables back into the ODE

  $4\left(\frac{\frac{d^2}{dt^2}y(t)}{x^2}-\frac{\frac{d}{dt}y(t)}{x^2}\right)x^2a^2+4\left(\frac{d}{dt}y(t)\right)a^2-(9a^2-4x^2)\,y(t)=0$

- Simplify

  $-9y(t)\,a^2+4y(t)\,x^2+4a^2\left(\frac{d^2}{dt^2}y(t)\right)=0$

- Isolate 2nd derivative

  $\frac{d^2}{dt^2}y(t)=\frac{(9a^2-4x^2)y(t)}{4a^2}$

- Group terms with $y(t)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d^2}{dt^2}y(t)-\frac{(9a^2-4x^2)y(t)}{4a^2}=0$

- Characteristic polynomial of ODE

  $r^2-\frac{9a^2-4x^2}{4a^2}=0$

- Factor the characteristic polynomial

  $\frac{4r^2a^2-9a^2+4x^2}{4a^2}=0$

- Roots of the characteristic polynomial

  $r=\left(\frac{\sqrt{9a^2-4x^2}}{2a},-\frac{\sqrt{9a^2-4x^2}}{2a}\right)$

- 1st solution of the ODE

  $y_1(t)=\mathrm{e}^{\frac{\sqrt{9a^2-4x^2}\,t}{2a}}$

- 2nd solution of the ODE

  $y_2(t)=\mathrm{e}^{-\frac{\sqrt{9a^2-4x^2}\,t}{2a}}$

- General solution of the ODE

  $y(t)=C1y_1(t)+C2y_2(t)$

- Substitute in solutions

  $$y(t) = C1\,\mathrm{e}^{\frac{\sqrt{9a^2-4x^2}\,t}{2a}} + C2\,\mathrm{e}^{-\frac{\sqrt{9a^2-4x^2}\,t}{2a}}$$

- Change variables back using $t = \ln(x)$

  $$y(x) = C1\,\mathrm{e}^{\frac{\sqrt{9a^2-4x^2}\,\ln(x)}{2a}} + C2\,\mathrm{e}^{-\frac{\sqrt{9a^2-4x^2}\,\ln(x)}{2a}}$$

- Simplify

  $$y(x) = C1\,x^{\frac{\sqrt{9a^2-4x^2}}{2a}} + C2\,x^{-\frac{\sqrt{9a^2-4x^2}}{2a}}$$

Solve

$$x^2y'' + xy' + \left(x^2 - \frac{25}{4}\right) y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.303 (sec)

Writing the ode as

$$x^2y'' + xy' + \left(x^2 - \frac{25}{4}\right) y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= x \\ C &= x^2 - \frac{25}{4} \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A} dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-x^2 + 6}{x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -x^2 + 6 \\ t &= x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{-x^2+6}{x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.536: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -1 + \frac{6}{x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = 6$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 3 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -2 \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx i - \frac{3i}{x^2} - \frac{9i}{2x^4} - \frac{27i}{2x^6} - \frac{405i}{8x^8} - \frac{1701i}{8x^{10}} - \frac{15309i}{16x^{12}} - \frac{72171i}{16x^{14}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = i$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= i \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = -1$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{-x^2 + 6}{x^2} \\ &= Q + \frac{R}{x^2} \\ &= (-1) + \left(\frac{6}{x^2}\right) \\ &= -1 + \frac{6}{x^2} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is 0. Dividing this by leading coefficient in t which is 1 gives 0. Now b can be found.

$$\begin{aligned} b &= (0) - (0) \\ &= 0 \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= i \\ \alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) = \frac{1}{2}\left(\frac{0}{i} - 0\right) = 0 \\ \alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) = \frac{1}{2}\left(-\frac{0}{i} - 0\right) = 0 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{-x^2+6}{x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	3	-2

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	i	0	0

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 0$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\
&= 0 - (-2) \\
&= 2
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{2}{x} + (-)(i) \\
&= -\frac{2}{x} - i \\
&= -\frac{2}{x} - i
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 2$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}$$

Let

$$p(x) = x^2 + a_1 x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned}
(2) + 2\left(-\frac{2}{x} - i\right)(2x + a_1) + \left(\left(\frac{2}{x^2}\right) + \left(-\frac{2}{x} - i\right)^2 - \left(\frac{-x^2+6}{x^2}\right)\right) &= 0 \\
\frac{2ixa_1 + 4ia_0 - 6x - 4a_1}{x} &= 0
\end{aligned}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = -3, a_1 = -3i\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^2 - 3ix - 3$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= pe^{\int \omega\, dx} \\ &= \left(x^2 - 3ix - 3\right) \mathrm{e}^{\int \left(-\frac{2}{x} - i\right) dx} \\ &= \left(x^2 - 3ix - 3\right) \mathrm{e}^{-2\ln(x) - ix} \\ &= \frac{\left(x^2 - 3ix - 3\right) \mathrm{e}^{-ix}}{x^2} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2} \frac{x}{x^2}\, dx} \\ &= z_1 e^{-\frac{\ln(x)}{2}} \\ &= z_1 \left(\frac{1}{\sqrt{x}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{\left(x^2 - 3ix - 3\right) \mathrm{e}^{-ix}}{x^{5/2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{x}{x^2}\, dx}}{\left(y_1\right)^2}\, dx \\ &= y_1 \int \frac{e^{-\ln(x)}}{\left(y_1\right)^2}\, dx \\ &= y_1 \left(\frac{\left(i x^2 - 3x - 3i\right) \mathrm{e}^{2ix}}{-2x^2 + 6ix + 6}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\frac{\left(x^2 - 3ix - 3\right) \mathrm{e}^{-ix}}{x^{5/2}}\right) + c_2 \left(\frac{\left(x^2 - 3ix - 3\right) \mathrm{e}^{-ix}}{x^{5/2}} \left(\frac{\left(i x^2 - 3x - 3i\right) \mathrm{e}^{2ix}}{-2x^2 + 6ix + 6}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2\left(\frac{d^2}{dx^2}y(x)\right)+x\left(\frac{d}{dx}y(x)\right)+\left(x^2-\frac{25}{4}\right)y(x)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x)=-\frac{(4x^2-25)y(x)}{4x^2}-\frac{\frac{d}{dx}y(x)}{x}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x)+\frac{\frac{d}{dx}y(x)}{x}+\frac{(4x^2-25)y(x)}{4x^2}=0$

□ Check to see if $x_0=0$ is a regular singular point

  ◦ Define functions

Solve

$$y'' + qy' = \frac{2y}{x^2}$$

Solved as second order ode using Kovacic algorithm

Time used: 0.276 (sec)

Writing the ode as

$$y'' + qy' - \frac{2y}{x^2} = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= q \\ C &= -\frac{2}{x^2} \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{q^2x^2 + 8}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= q^2x^2 + 8 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{q^2x^2+8}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.538: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{q^2}{4} + \frac{2}{x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1 \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{q}{2} + \frac{2}{q\,x^2} - \frac{4}{q^3 x^4} + \frac{16}{q^5 x^6} - \frac{80}{q^7 x^8} + \frac{448}{q^9 x^{10}} - \frac{2688}{q^{11} x^{12}} + \frac{16896}{q^{13} x^{14}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{q}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{q}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{q^2}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{q^2 x^2 + 8}{4x^2} \\ &= Q + \frac{R}{4x^2} \\ &= \left(\frac{q^2}{4}\right) + \left(\frac{2}{x^2}\right) \\ &= \frac{q^2}{4} + \frac{2}{x^2} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is 0. Dividing this by leading coefficient in t which is 4 gives 0. Now b can be found.

$$\begin{aligned} b &= (0) - (0) \\ &= 0 \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{q}{2} \\ \alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{0}{\frac{q}{2}} - 0\right) &&= 0 \\ \alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{0}{\frac{q}{2}} - 0\right) &&= 0 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{q^2x^2 + 8}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	2	-1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{q}{2}$	0	0

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 0$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\
&= 0 - (-1) \\
&= 1
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x - c_1} \right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{1}{x} + (-)\left(\frac{q}{2}\right) \\
&= -\frac{1}{x} - \frac{q}{2} \\
&= -\frac{qx + 2}{2x}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{x} - \frac{q}{2}\right)(1) + \left(\left(\frac{1}{x^2}\right) + \left(-\frac{1}{x} - \frac{q}{2}\right)^2 - \left(\frac{q^2x^2 + 8}{4x^2}\right)\right) = 0$$

$$\frac{qa_0 - 2}{x} = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\left\{a_0 = \frac{2}{q}\right\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x + \frac{2}{q}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= \left(x + \frac{2}{q}\right) e^{\int \left(-\frac{1}{x} - \frac{q}{2}\right) dx} \\ &= \left(x + \frac{2}{q}\right) e^{-\frac{qx}{2} - \ln(x)} \\ &= \frac{(qx+2)\, e^{-\frac{qx}{2}}}{qx} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2} \frac{q}{1} \, dx} \\ &= z_1 e^{-\frac{qx}{2}} \\ &= z_1 \left(e^{-\frac{qx}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{e^{-qx}(qx+2)}{qx}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{q}{1} \, dx}}{(y_1)^2} \, dx \\ &= y_1 \int \frac{e^{-qx}}{(y_1)^2} \, dx \\ &= y_1 \left(\frac{(qx-2)\, e^{qx}}{q\,(qx+2)}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\frac{e^{-qx}(qx+2)}{qx}\right) + c_2 \left(\frac{e^{-qx}(qx+2)}{qx} \left(\frac{(qx-2)\, e^{qx}}{q\,(qx+2)}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$\frac{d^2}{dx^2}y(x) + q\left(\frac{d}{dx}y(x)\right) = \frac{2y(x)}{x^2}$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -q\left(\frac{d}{dx}y(x)\right) + \frac{2y(x)}{x^2}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lir

  $\frac{d^2}{dx^2}y(x) + q\left(\frac{d}{dx}y(x)\right) - \frac{2y(x)}{x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $\left.(x^2 \cdot P_3(x))\right|_{x=0} = -2$

  ◦ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $q\left(\frac{d}{dx}y(x)\right)x^2 + x^2\left(\frac{d^2}{dx^2}y(x)\right) - 2y(x) = 0$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $x^2 \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion

  $x^2 \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r+1}$

  ◦ Shift index using $k->k-1$

  $x^2 \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=1}^{\infty} a_{k-1}(k-1+r)\,x^{k+r}$

  ◦ Convert $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

  $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k-1+r)\,x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(1+r)\,(-2+r)\,x^r + \left(\sum_{k=1}^{\infty} \left(a_k(k+r+1)\,(k+r-2) + q a_{k-1}(k-1+r)\right)x^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(1+r)\,(-2+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{-1, 2\}$

- Each term in the series must be 0, giving the recursion relation

  $a_k(k+r+1)\,(k+r-2) + q a_{k-1}(k-1+r) = 0$

- Shift index using $k->k+1$

  $a_{k+1}(k+2+r)\,(k-1+r) + q a_k(k+r) = 0$

- Recursion relation that defines series solution to ODE
  $a_{k+1} = -\frac{q a_k (k+r)}{(k+2+r)(k-1+r)}$
- Recursion relation for $r = -1$; series terminates at $k = 1$
  $a_{k+1} = -\frac{q a_k (k-1)}{(k+1)(k-2)}$
- Apply recursion relation for $k = 0$
  $a_1 = -\frac{q a_0}{2}$
- Terminating series solution of the ODE for $r = -1$. Use reduction of order to find the second lin
  $y(x) = a_0 \cdot \left(-\frac{qx}{2} + 1\right)$
- Recursion relation for $r = 2$
  $a_{k+1} = -\frac{q a_k (k+2)}{(k+4)(k+1)}$
- Solution for $r = 2$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+2}, a_{k+1} = -\frac{q a_k (k+2)}{(k+4)(k+1)}\right]$
- Combine solutions and rename parameters
  $\left[y(x) = a_0 \cdot \left(-\frac{qx}{2} + 1\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+2}\right), b_{k+1} = -\frac{q b_k (k+2)}{(4+k)(k+1)}\right]$

$$y(x) \to \frac{2qx^{3/2} e^{\frac{1}{2}-\frac{qx}{2}} \left((c_1 qx + 2ic_2)\cosh\left(\frac{qx}{2}\right) - (ic_2 qx + 2c_1)\sinh\left(\frac{qx}{2}\right)\right)}{\sqrt{\pi}(-iqx)^{5/2}}$$

2.1.283 Problem 286

Internal problem ID [9455]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 286
Date solved : `Monday, January 27, 2025 at 06:03:01 PM`
CAS classification : `[[_Emden, _Fowler]]`

Solve

$$xy'' + 3y' + 4x^3y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.261 (sec)

Writing the ode as

$$xy'' + 3y' + 4x^3y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x \\ B &= 3 \\ C &= 4x^3 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-16x^4 + 3}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -16x^4 + 3 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{-16x^4 + 3}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.540: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 4 \\ &= -2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -4x^2 + \frac{3}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx 2ix - \frac{3i}{16x^3} - \frac{9i}{1024x^7} - \frac{27i}{32768x^{11}} - \frac{405i}{4194304x^{15}} - \frac{1701i}{134217728x^{19}} - \frac{15309i}{8589934592x^{23}} - \frac{72171i}{274877906944x^{27}} + \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = 2i$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= 2ix \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = -4x^2$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{-16x^4 + 3}{4x^2} \\ &= Q + \frac{R}{4x^2} \\ &= (-4x^2) + \left(\frac{3}{4x^2}\right) \\ &= -4x^2 + \frac{3}{4x^2} \end{aligned}$$

We see that the coefficient of the term x in the quotient is 0. Now b can be found.

$$\begin{aligned} b &= (0) - (0) \\ &= 0 \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= 2ix \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{0}{2i} - 1\right) &&= -\frac{1}{2} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{0}{2i} - 1\right) &&= -\frac{1}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{-16x^4 + 3}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-2	$2ix$	$-\frac{1}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -\frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\ &= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= -\frac{1}{2x} + (-)\left(2ix\right) \\ &= -\frac{1}{2x} - 2ix \\ &= -\frac{1}{2x} - 2ix \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(-\frac{1}{2x} - 2ix\right)(0) + \left(\left(\frac{1}{2x^2} - 2i\right) + \left(-\frac{1}{2x} - 2ix\right)^2 - \left(\frac{-16x^4+3}{4x^2}\right) \right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega\, dx} \\ &= e^{\int \left(-\frac{1}{2x} - 2ix\right) dx} \\ &= \frac{e^{-ix^2}}{\sqrt{x}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{3}{x}\,dx} \\ &= z_1 e^{-\frac{3\ln(x)}{2}} \\ &= z_1\left(\frac{1}{x^{3/2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{\mathrm{e}^{-ix^2}}{x^2}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{3}{x}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{-3\ln(x)}}{(y_1)^2}\,dx \\ &= y_1\left(-\frac{i\mathrm{e}^{2ix^2}}{4}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\frac{\mathrm{e}^{-ix^2}}{x^2}\right) + c_2\left(\frac{\mathrm{e}^{-ix^2}}{x^2}\left(-\frac{i\mathrm{e}^{2ix^2}}{4}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve
$\left(\frac{d^2}{dx^2}y(x)\right)x + 3\frac{d}{dx}y(x) + 4x^3y(x) = 0$

- Highest derivative means the order of the ODE is 2
  $\frac{d^2}{dx^2}y(x)$
- Isolate 2nd derivative
  $\frac{d^2}{dx^2}y(x) = -4x^2y(x) - \frac{3\left(\frac{d}{dx}y(x)\right)}{x}$
- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin
  $\frac{d^2}{dx^2}y(x) + \frac{3\left(\frac{d}{dx}y(x)\right)}{x} + 4x^2y(x) = 0$

☐ Check to see if $x_0 = 0$ is a regular singular point
  - Define functions
    $\left[P_2(x) = \frac{3}{x}, P_3(x) = 4x^2\right]$
  - $x \cdot P_2(x)$ is analytic at $x = 0$

$\left(x \cdot P_2(x)\right)\Big|_{x=0} = 3$

- $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $\left(x^2 \cdot P_3(x)\right)\Big|_{x=0} = 0$

- $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $\left(\frac{d^2}{dx^2}y(x)\right)x + 3\frac{d}{dx}y(x) + 4x^3y(x) = 0$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

- □ Rewrite ODE with series expansions

  - Convert $x^3 \cdot y(x)$ to series expansion

    $x^3 \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+3}$

  - Shift index using $k- >k-3$

    $x^3 \cdot y(x) = \sum_{k=3}^{\infty} a_{k-3} x^{k+r}$

  - Convert $\frac{d}{dx}y(x)$ to series expansion

    $\frac{d}{dx}y(x) = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1}$

  - Shift index using $k- >k+1$

    $\frac{d}{dx}y(x) = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\,x^{k+r}$

  - Convert $x \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

    $x \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r-1}$

  - Shift index using $k- >k+1$

    $x \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\,(k+r)\,x^{k+r}$

  Rewrite ODE with series expansions

  $a_0r(2+r)\,x^{-1+r} + a_1(1+r)\,(3+r)\,x^r + a_2(2+r)\,(4+r)\,x^{1+r} + a_3(3+r)\,(5+r)\,x^{2+r} + \left(\sum_{k=3}^{\infty} (a_{k+\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r(2+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{-2, 0\}$

- The coefficients of each power of x must be 0

  $[a_1(1+r)\,(3+r) = 0, a_2(2+r)\,(4+r) = 0, a_3(3+r)\,(5+r) = 0]$

- Solve for the dependent coefficient(s)

  $\{a_1 = 0, a_2 = 0, a_3 = 0\}$

- Each term in the series must be 0, giving the recursion relation

  $a_{k+1}(k+1+r)\,(k+r+3) + 4a_{k-3} = 0$

- Shift index using $k- >k+3$

  $a_{k+4}(k+4+r)\,(k+6+r) + 4a_k = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+4} = -\frac{4a_k}{(k+4+r)(k+6+r)}$

- Recursion relation for $r = -2$

  $a_{k+4} = -\frac{4a_k}{(k+2)(k+4)}$
- Solution for $r = -2$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k-2}, a_{k+4} = -\frac{4a_k}{(k+2)(k+4)}, a_1 = 0, a_2 = 0, a_3 = 0\right]$
- Recursion relation for $r = 0$

  $a_{k+4} = -\frac{4a_k}{(k+4)(k+6)}$
- Solution for $r = 0$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k}, a_{k+4} = -\frac{4a_k}{(k+4)(k+6)}, a_1 = 0, a_2 = 0, a_3 = 0\right]$
- Combine solutions and rename parameters

  $\left[y(x) = \left(\sum_{k=0}^{\infty} a_k x^{k-2}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k}\right), a_{4+k} = -\frac{4a_k}{(k+2)(4+k)}, a_1 = 0, a_2 = 0, a_3 = 0, b_{4+k} = -\frac{4b_k}{(4+k)(k}\right.$

2.1.284 Problem 287

Internal problem ID [9456]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 287
Date solved : `Monday, January 27, 2025 at 06:03:01 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$\left(x^2+2x\right)y''-2(x+1)\,y'+2y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.209 (sec)

Writing the ode as

$$\left(x^2+2x\right)y''+(-2x-2)\,y'+2y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=x^2+2x\\B&=-2x-2\\C&=2\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned}r&=\frac{s}{t}\\&=\frac{2AB'-2BA'+B^2-4AC}{4A^2}\end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{3}{\left(x^2+2x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned}s&=3\\t&=\left(x^2+2x\right)^2\end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{3}{\left(x^2+2x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.542: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 0 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (x^2 + 2x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -2$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{3}{4x^2} + \frac{3}{4(x+2)} - \frac{3}{4x} + \frac{3}{4(x+2)^2}$$

For the pole at $x = -2$ let b be the coefficient of $\frac{1}{(x+2)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $4>2$ then

$$\begin{aligned}[\sqrt{r}]_\infty &= 0\\ \alpha_\infty^+ &= 0\\ \alpha_\infty^- &= 1\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{3}{(x^2+2x)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
-2	2	0	$\frac{3}{2}$	$-\frac{1}{2}$
0	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$ then

$$\begin{aligned}d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^+\right)\\ &= 1-(1)\\ &= 0\end{aligned}$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x-c_2}\right) + (-)[\sqrt{r}]_\infty\\ &= -\frac{1}{2\,(x+2)} + \frac{3}{2x} + (-)\,(0)\\ &= -\frac{1}{2\,(x+2)} + \frac{3}{2x}\\ &= \frac{x+3}{x\,(x+2)}\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(-\frac{1}{2(x+2)}+\frac{3}{2x}\right)(0)+\left(\left(\frac{1}{2(x+2)^2}-\frac{3}{2x^2}\right)+\left(-\frac{1}{2(x+2)}+\frac{3}{2x}\right)^2-\left(\frac{3}{(x^2+2x)^2}\right)\right)=0$$
$$0=0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z''=rz$ is

$$\begin{aligned} z_1(x) &= pe^{\int \omega\,dx} \\ &= \mathrm{e}^{\int \left(-\frac{1}{2(x+2)}+\frac{3}{2x}\right)dx} \\ &= \frac{x^{3/2}}{\sqrt{x+2}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-2x-2}{x^2+2x}\,dx} \\ &= z_1 e^{\frac{\ln(x(x+2))}{2}} \\ &= z_1\left(\sqrt{x(x+2)}\right) \end{aligned}$$

Which simplifies to

$$y_1=\frac{\sqrt{x(x+2)}\,x^{3/2}}{\sqrt{x+2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2=y_1\int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1\int \frac{e^{\int -\frac{-2x-2}{x^2+2x}\,dx}}{(y_1)^2}\,dx \\ &= y_1\int \frac{e^{\ln(x(x+2))}}{(y_1)^2}\,dx \\ &= y_1\left(-\frac{1}{x}-\frac{1}{x^2}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1y_1+c_2y_2 \\ &= c_1\left(\frac{\sqrt{x(x+2)}\,x^{3/2}}{\sqrt{x+2}}\right)+c_2\left(\frac{\sqrt{x(x+2)}\,x^{3/2}}{\sqrt{x+2}}\left(-\frac{1}{x}-\frac{1}{x^2}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$(x^2+2x)\left(\frac{d^2}{dx^2}y(x)\right)-2(x+1)\left(\frac{d}{dx}y(x)\right)+2y(x)=0$

- Highest derivative means the order of the ODE is 2

$\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

$\frac{d^2}{dx^2}y(x)=-\frac{2y(x)}{x(x+2)}+\frac{2(x+1)\left(\frac{d}{dx}y(x)\right)}{x(x+2)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

$\frac{d^2}{dx^2}y(x)-\frac{2(x+1)\left(\frac{d}{dx}y(x)\right)}{x(x+2)}+\frac{2y(x)}{x(x+2)}=0$

□ Check to see if x_0 is a regular singular point

◦ Define functions

$\left[P_2(x)=-\frac{2(x+1)}{x(x+2)}, P_3(x)=\frac{2}{x(x+2)}\right]$

◦ $(x+2)\cdot P_2(x)$ is analytic at $x=-2$

$\left((x+2)\cdot P_2(x)\right)\bigg|_{x=-2}=-1$

◦ $(x+2)^2\cdot P_3(x)$ is analytic at $x=-2$

$\left((x+2)^2\cdot P_3(x)\right)\bigg|_{x=-2}=0$

◦ $x=-2$is a regular singular point

Check to see if x_0 is a regular singular point

$x_0=-2$

- Multiply by denominators

$x(x+2)\left(\frac{d^2}{dx^2}y(x)\right)+(-2-2x)\left(\frac{d}{dx}y(x)\right)+2y(x)=0$

- Change variables using $x=u-2$ so that the regular singular point is at $u=0$

$(u^2-2u)\left(\frac{d^2}{du^2}y(u)\right)+(2-2u)\left(\frac{d}{du}y(u)\right)+2y(u)=0$

- Assume series solution for $y(u)$

$y(u)=\sum_{k=0}^{\infty} a_k u^{k+r}$

□ Rewrite ODE with series expansions

◦ Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$

$u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty} a_k(k+r)\,u^{k+r-1+m}$

◦ Shift index using $k->k+1-m$

$u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,u^{k+r}$

◦ Convert $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m=1..2$

$u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\,u^{k+r-2+m}$

◦ Shift index using $k->k+2-m$

$u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\,u^{k+r}$

Rewrite ODE with series expansions

$-2a_0r(-2+r)\,u^{-1+r}+\left(\sum_{k=0}^{\infty}\left(-2a_{k+1}(k+1+r)(k+r-1)+a_k(k+r-1)(k+r-2)\right)u^{k+r}\right)=$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$-2r(-2+r)=0$

- Values of r that satisfy the indicial equation

  $r\in\{0,2\}$

- Each term in the series must be 0, giving the recursion relation

  $((-2k-2r-2)\,a_{k+1}+a_k(k+r-2))\,(k+r-1)=0$

- Recursion relation that defines series solution to ODE

  $a_{k+1}=\frac{a_k(k+r-2)}{2(k+1+r)}$

- Recursion relation for $r=0$; series terminates at $k=2$

  $a_{k+1}=\frac{a_k(k-2)}{2(k+1)}$

- Apply recursion relation for $k=0$

  $a_1=-a_0$

- Apply recursion relation for $k=1$

  $a_2=-\frac{a_1}{4}$

- Express in terms of a_0

  $a_2=\frac{a_0}{4}$

- Terminating series solution of the ODE for $r=0$. Use reduction of order to find the second li

  $y(u)=a_0\cdot\left(1-u+\frac{1}{4}u^2\right)$

- Revert the change of variables $u=x+2$

  $\left[y(x)=\frac{a_0x^2}{4}\right]$

- Recursion relation for $r=2$

  $a_{k+1}=\frac{a_kk}{2(k+3)}$

- Solution for $r=2$

  $\left[y(u)=\sum_{k=0}^{\infty}a_ku^{k+2}, a_{k+1}=\frac{a_kk}{2(k+3)}\right]$

- Revert the change of variables $u=x+2$

  $\left[y(x)=\sum_{k=0}^{\infty}a_k(x+2)^{k+2}, a_{k+1}=\frac{a_kk}{2(k+3)}\right]$

- Combine solutions and rename parameters

  $\left[y(x)=\frac{a_0x^2}{4}+\left(\sum_{k=0}^{\infty}b_k(x+2)^{k+2}\right), b_{k+1}=\frac{b_kk}{2(k+3)}\right]$

2.1.285 Problem 288

Internal problem ID [9457]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 288
Date solved : `Monday, January 27, 2025 at 06:03:02 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$\left(x^{2}+2 x \right) y''-2(x+1) y'+2 y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.209 (sec)

Writing the ode as

$$\left(x^{2}+2 x \right) y''+\left(-2 x -2\right) y'+2 y = 0 \tag{1}$$
$$A y'' + B y' + C y = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^{2}+2 x \\ B &= -2 x -2 \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2 A} \,dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2 A B' - 2 B A' + B^2 - 4 A C}{4 A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r = \frac{3}{\left(x^{2}+2 x \right)^{2}} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 3 \\ t &= \left(x^{2}+2 x \right)^{2} \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{3}{\left(x^{2}+2 x \right)^{2}}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\,e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.544: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s)\\ &= 4 - 0\\ &= 4\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (x^2+2x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -2$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{3}{4x^2} - \frac{3}{4x} + \frac{3}{4(x+2)} + \frac{3}{4(x+2)^2}$$

For the pole at $x = -2$ let b be the coefficient of $\frac{1}{(x+2)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2}\\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}\end{aligned}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2}\\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}\end{aligned}$$

Since the order of r at ∞ is $4 > 2$ then

$$\begin{aligned}[\sqrt{r}]_\infty &= 0\\ \alpha_\infty^+ &= 0\\ \alpha_\infty^- &= 1\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{3}{(x^2+2x)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
-2	2	0	$\frac{3}{2}$	$-\frac{1}{2}$
0	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$ then

$$\begin{aligned}d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^+\right)\\ &= 1 - (1)\\ &= 0\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x-c_2}\right) + (-)[\sqrt{r}]_\infty\\ &= -\frac{1}{2(x+2)} + \frac{3}{2x} + (-)(0)\\ &= -\frac{1}{2(x+2)} + \frac{3}{2x}\\ &= \frac{x+3}{x(x+2)}\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(-\frac{1}{2\left(x+2\right)}+\frac{3}{2x}\right)(0)+\left(\left(\frac{1}{2\left(x+2\right)^{2}}-\frac{3}{2x^{2}}\right)+\left(-\frac{1}{2\left(x+2\right)}+\frac{3}{2x}\right)^{2}-\left(\frac{3}{\left(x^{2}+2x\right)^{2}}\right)\right)=0$$

$$0=0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z''=rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= \mathrm{e}^{\int \left(-\frac{1}{2(x+2)}+\frac{3}{2x}\right)dx} \\ &= \frac{x^{3/2}}{\sqrt{x+2}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-2x-2}{x^2+2x}\, dx} \\ &= z_1 e^{\frac{\ln(x(x+2))}{2}} \\ &= z_1\left(\sqrt{x\left(x+2\right)}\right) \end{aligned}$$

Which simplifies to

$$y_1=\frac{\sqrt{x\left(x+2\right)}\, x^{3/2}}{\sqrt{x+2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2=y_1\int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1\int \frac{e^{\int -\frac{-2x-2}{x^2+2x}\, dx}}{\left(y_1\right)^2}\, dx \\ &= y_1\int \frac{e^{\ln(x(x+2))}}{\left(y_1\right)^2}\, dx \\ &= y_1\left(-\frac{1}{x^2}-\frac{1}{x}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\frac{\sqrt{x\left(x+2\right)}\, x^{3/2}}{\sqrt{x+2}}\right)+c_2\left(\frac{\sqrt{x\left(x+2\right)}\, x^{3/2}}{\sqrt{x+2}}\left(-\frac{1}{x^2}-\frac{1}{x}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$\left(x^2+1\right) y''-2 x y'+2 y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.258 (sec)

Writing the ode as

$$\left(x^2+1\right) y''-2 x y'+2 y=0 \tag{1}$$
$$A y''+B y'+C y=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2+1 \\ B &= -2x \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x)=r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r=\frac{-3}{\left(x^2+1\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -3 \\ t &= \left(x^2+1\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(-\frac{3}{\left(x^2+1\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.546: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 0 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (x^2+1)^2$. There is a pole at $x = i$ of order 2. There is a pole at $x = -i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{3}{4(x-i)^2} + \frac{3}{4(x+i)^2} + \frac{3i}{4(x-i)} - \frac{3i}{4(x+i)}$$

For the pole at $x = i$ let b be the coefficient of $\frac{1}{(x-i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

For the pole at $x = -i$ let b be the coefficient of $\frac{1}{(x+i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $4 > 2$ then

$$\begin{aligned}[\sqrt{r}]_\infty &= 0\\ \alpha_\infty^+ &= 0\\ \alpha_\infty^- &= 1\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = -\frac{3}{(x^2+1)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
i	2	0	$\frac{3}{2}$	$-\frac{1}{2}$
$-i$	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$ then

$$\begin{aligned}d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^+\right)\\ &= 1 - (1)\\ &= 0\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x-c_2}\right) + (-)[\sqrt{r}]_\infty\\ &= -\frac{1}{2(x-i)} + \frac{3}{2(x+i)} + (-)(0)\\ &= -\frac{1}{2(x-i)} + \frac{3}{2(x+i)}\\ &= \frac{x-2i}{x^2+1}\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{2\left(x-i\right)} + \frac{3}{2\left(x+i\right)}\right)(0) + \left(\left(\frac{1}{2\left(x-i\right)^{2}} - \frac{3}{2\left(x+i\right)^{2}}\right) + \left(-\frac{1}{2\left(x-i\right)} + \frac{3}{2\left(x+i\right)}\right)^{2} - \left(-\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= \mathrm{e}^{\int \left(-\frac{1}{2(x-i)} + \frac{3}{2(x+i)}\right) dx} \\ &= \frac{\left(x^{2}+1\right)^{3/2}}{\left(ix+1\right)^{2}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2} \frac{-2x}{x^{2}+1} \, dx} \\ &= z_1 e^{\frac{\ln\left(x^{2}+1\right)}{2}} \\ &= z_1 \left(\sqrt{x^{2}+1}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{\left(x^{2}+1\right)^{2}}{\left(ix+1\right)^{2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^{2}} \, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-2x}{x^{2}+1} \, dx}}{\left(y_1\right)^{2}} \, dx \\ &= y_1 \int \frac{e^{\ln\left(x^{2}+1\right)}}{\left(y_1\right)^{2}} \, dx \\ &= y_1 \left(-\frac{x}{\left(x+i\right)^{2}}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\frac{\left(x^{2}+1\right)^{2}}{\left(ix+1\right)^{2}}\right) + c_2 \left(\frac{\left(x^{2}+1\right)^{2}}{\left(ix+1\right)^{2}} \left(-\frac{x}{\left(x+i\right)^{2}}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

2.1.287 Problem 290

Internal problem ID [9459]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 290
Date solved : `Monday, January 27, 2025 at 06:03:03 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$\left(x^2+1\right) y''-2xy'+2y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.270 (sec)

Writing the ode as

$$\left(x^2+1\right) y''-2xy'+2y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2+1 \\ B &= -2x \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r=\frac{-3}{\left(x^2+1\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -3 \\ t &= \left(x^2+1\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(-\frac{3}{\left(x^2+1\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.547: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 0 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (x^2+1)^2$. There is a pole at $x = i$ of order 2. There is a pole at $x = -i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{3}{4(x-i)^2} + \frac{3}{4(x+i)^2} + \frac{3i}{4(x-i)} - \frac{3i}{4(x+i)}$$

For the pole at $x = i$ let b be the coefficient of $\frac{1}{(x-i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

For the pole at $x = -i$ let b be the coefficient of $\frac{1}{(x+i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $4 > 2$ then

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= 0 \\
\alpha_\infty^{-} &= 1
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = -\frac{3}{(x^2+1)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
i	2	0	$\frac{3}{2}$	$-\frac{1}{2}$
$-i$	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = 1$ then

$$
\begin{aligned}
d &= \alpha_\infty^{-} - \left(\alpha_{c_1}^{-} + \alpha_{c_2}^{+}\right) \\
&= 1 - (1) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x-c_1} \right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{+}}{x-c_2} \right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{1}{2\,(x-i)} + \frac{3}{2\,(x+i)} + (-)\,(0) \\
&= -\frac{1}{2\,(x-i)} + \frac{3}{2\,(x+i)} \\
&= \frac{x-2i}{x^2+1}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(-\frac{1}{2\left(x-i\right)}+\frac{3}{2\left(x+i\right)}\right)(0)+\left(\left(\frac{1}{2\left(x-i\right)^{2}}-\frac{3}{2\left(x+i\right)^{2}}\right)+\left(-\frac{1}{2\left(x-i\right)}+\frac{3}{2\left(x+i\right)}\right)^{2}-\left(-\frac{}{(x^{2}}\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z''=rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(-\frac{1}{2(x-i)}+\frac{3}{2(x+i)}\right)dx} \\
&= \frac{\left(x^{2}+1\right)^{3/2}}{\left(ix+1\right)^{2}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-2x}{x^2+1}\, dx} \\
&= z_1 e^{\frac{\ln\left(x^2+1\right)}{2}} \\
&= z_1\left(\sqrt{x^{2}+1}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{\left(x^{2}+1\right)^{2}}{\left(ix+1\right)^{2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-2x}{x^2+1}\, dx}}{\left(y_1\right)^2}\, dx \\
&= y_1 \int \frac{e^{\ln\left(x^2+1\right)}}{\left(y_1\right)^2}\, dx \\
&= y_1\left(-\frac{x}{\left(x+i\right)^{2}}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{\left(x^{2}+1\right)^{2}}{\left(ix+1\right)^{2}}\right)+c_2\left(\frac{\left(x^{2}+1\right)^{2}}{\left(ix+1\right)^{2}}\left(-\frac{x}{\left(x+i\right)^{2}}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

2.1.288 Problem 291

Internal problem ID [9460]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 291
Date solved : `Monday, January 27, 2025 at 06:03:04 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$y'' - 4xy' + (4x^2 - 2)\, y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.058 (sec)

Writing the ode as

$$y'' - 4xy' + (4x^2 - 2)\, y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -4x \\ C &= 4x^2 - 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$s = 0$$
$$t = 1$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.548: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-4x}{1}\, dx} \\ &= z_1 e^{x^2} \\ &= z_1\left(\mathrm{e}^{x^2}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{x^2}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-4x}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{2x^2}}{(y_1)^2}\,dx \\ &= y_1(x) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\mathrm{e}^{x^2}\right) + c_2\left(\mathrm{e}^{x^2}(x)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve
$\frac{d^2}{dx^2}y(x) - 4x\left(\frac{d}{dx}y(x)\right) + (4x^2 - 2)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2
$\frac{d^2}{dx^2}y(x)$
- Assume series solution for $y(x)$
$y(x) = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite ODE with series expansions
  - Convert $x^m \cdot y(x)$ to series expansion for $m = 0..2$
  $x^m \cdot y(x) = \sum_{k=\max(0,-m)}^{\infty} a_k x^{k+m}$
  - Shift index using $k- >k - m$
  $x^m \cdot y(x) = \sum_{k=\max(0,-m)+m}^{\infty} a_{k-m} x^k$
  - Convert $x \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion
  $x \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k k\, x^k$
  - Convert $\frac{d^2}{dx^2}y(x)$ to series expansion
  $\frac{d^2}{dx^2}y(x) = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$
  - Shift index using $k- >k + 2$
  $\frac{d^2}{dx^2}y(x) = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$

  Rewrite ODE with series expansions
  $2a_2 - 2a_0 + (6a_3 - 6a_1)\,x + \left(\sum_{k=2}^{\infty} (a_{k+2}(k+2)\,(k+1) - 2a_k(2k+1) + 4a_{k-2})\, x^k\right) = 0$

- The coefficients of each power of x must be 0
$[2a_2 - 2a_0 = 0, 6a_3 - 6a_1 = 0]$
- Solve for the dependent coefficient(s)
$\{a_2 = a_0, a_3 = a_1\}$
- Each term in the series must be 0, giving the recursion relation
$(k^2 + 3k + 2)\,a_{k+2} - 4a_k k - 2a_k + 4a_{k-2} = 0$

- Shift index using $k->k+2$

  $$\left((k+2)^2+3k+8\right)a_{k+4}-4a_{k+2}(k+2)-2a_{k+2}+4a_k=0$$

- Recursion relation that defines the series solution to the ODE

  $$\left[y(x)=\sum_{k=0}^{\infty}a_k x^k, a_{k+4}=\frac{2(2ka_{k+2}-2a_k+5a_{k+2})}{k^2+7k+12}, a_2=a_0, a_3=a_1\right]$$

2.1.289 Problem 292

Internal problem ID [9461]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 292
Date solved : `Monday, January 27, 2025 at 06:03:04 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$y'' - 4xy' + (4x^2 - 2)\,y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.053 (sec)

Writing the ode as

$$y'' - 4xy' + (4x^2 - 2)\,y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -4x \\ C &= 4x^2 - 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.550: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-4x}{1}\, dx} \\ &= z_1 e^{x^2} \\ &= z_1 \left(e^{x^2}\right) \end{aligned}$$

Which simplifies to

$$y_1 = e^{x^2}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-4x}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{2x^2}}{(y_1)^2}\,dx \\
&= y_1(x)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{x^2}\right) + c_2\left(\mathrm{e}^{x^2}(x)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$\frac{d^2}{dx^2}y(x) - 4x\left(\frac{d}{dx}y(x)\right) + (4x^2 - 2)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

2.1.290 Problem 293

Internal problem ID [9462]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 293
Date solved : Monday, January 27, 2025 at 06:03:05 PM
CAS classification : [[_2nd_order, _with_linear_symmetries]]

Solve

$$(2x-3)\,y''-xy'+y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.353 (sec)

Writing the ode as

$$(2x-3)\,y''-xy'+y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=2x-3\\B&=-x\\C&=1\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned}r&=\frac{s}{t}\\&=\frac{2AB'-2BA'+B^2-4AC}{4A^2}\end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{x^2-8x+18}{4\,(2x-3)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned}s&=x^2-8x+18\\t&=4(2x-3)^2\end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{x^2-8x+18}{4\,(2x-3)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.552: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(2x-3)^2$. There is a pole at $x = \frac{3}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{16} + \frac{33}{64\left(x - \frac{3}{2}\right)^2} - \frac{5}{16\left(x - \frac{3}{2}\right)}$$

For the pole at $x = \frac{3}{2}$ let b be the coefficient of $\frac{1}{\left(x-\frac{3}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{33}{64}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^{+} &= \frac{1}{2} + \sqrt{1+4b} = \frac{11}{8} \\ \alpha_c^{-} &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{8} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{4} - \frac{5}{8x} - \frac{11}{16x^2} - \frac{1}{32x^3} + \frac{245}{64x^4} + \frac{2591}{128x^5} + \frac{21117}{256x^6} + \frac{154743}{512x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{4}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{4} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{16}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 - 8x + 18}{16x^2 - 48x + 36} \\ &= Q + \frac{R}{16x^2 - 48x + 36} \\ &= \left(\frac{1}{16}\right) + \left(\frac{-5x + \frac{63}{4}}{16x^2 - 48x + 36}\right) \\ &= \frac{1}{16} + \frac{-5x + \frac{63}{4}}{16x^2 - 48x + 36} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is -5. Dividing this by leading coefficient in t which is 16 gives $-\frac{5}{16}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{5}{16}\right) - (0) \\ &= -\frac{5}{16} \end{aligned}$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \frac{1}{4} \\
\alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{5}{16}}{\frac{1}{4}} - 0\right) &&= -\frac{5}{8} \\
\alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{5}{16}}{\frac{1}{4}} - 0\right) &&= \frac{5}{8}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{x^2 - 8x + 18}{4\left(2x - 3\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
$\frac{3}{2}$	2	0	$\frac{11}{8}$	$-\frac{3}{8}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
0	$\frac{1}{4}$	$-\frac{5}{8}$	$\frac{5}{8}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = \frac{5}{8}$ then

$$
\begin{aligned}
d &= \alpha_\infty^{-} - \left(\alpha_{c_1}^{-}\right) \\
&= \frac{5}{8} - \left(-\frac{3}{8}\right) \\
&= 1
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1} \right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{3}{8\left(x - \frac{3}{2}\right)} + (-)\left(\frac{1}{4}\right) \\
&= -\frac{3}{8\left(x - \frac{3}{2}\right)} - \frac{1}{4} \\
&= -\frac{x}{4x - 6}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = x + a_0 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(-\frac{3}{8\left(x-\frac{3}{2}\right)}-\frac{1}{4}\right)(1)+\left(\left(\frac{3}{8\left(x-\frac{3}{2}\right)^{2}}\right)+\left(-\frac{3}{8\left(x-\frac{3}{2}\right)}-\frac{1}{4}\right)^{2}-\left(\frac{x^{2}-8x+18}{4\left(2x-3\right)^{2}}\right)\right)=0$$

$$\frac{a_0}{2x-3}=0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0=0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x)=x$$

Therefore the first solution to the ode $z''=rz$ is

$$\begin{aligned}
z_1(x) &= pe^{\int \omega\,dx}\\
&= (x)\,\mathrm{e}^{\int\left(-\frac{3}{8\left(x-\frac{3}{2}\right)}-\frac{1}{4}\right)dx}\\
&= (x)\,\mathrm{e}^{-\frac{x}{4}-\frac{3\ln(2x-3)}{8}}\\
&= \frac{x\,\mathrm{e}^{-\frac{x}{4}}}{\left(2x-3\right)^{3/8}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}\\
&= z_1 e^{-\int \frac{1}{2}\frac{-x}{2x-3}\,dx}\\
&= z_1 e^{\frac{x}{4}+\frac{3\ln(2x-3)}{8}}\\
&= z_1\left(\left(2x-3\right)^{3/8}\mathrm{e}^{\frac{x}{4}}\right)
\end{aligned}$$

Which simplifies to

$$y_1=x$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2=y_1\int\frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1\int\frac{e^{\int -\frac{-x}{2x-3}\,dx}}{\left(y_1\right)^2}\,dx\\
&= y_1\int\frac{\mathrm{e}^{\frac{x}{2}+\frac{3\ln(2x-3)}{4}}}{\left(y_1\right)^2}\,dx\\
&= y_1\left(\int\frac{\mathrm{e}^{\frac{x}{2}+\frac{3\ln(2x-3)}{4}}}{x^2}dx\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1y_1+c_2y_2\\
&= c_1(x)+c_2\left(x\left(\int\frac{\mathrm{e}^{\frac{x}{2}+\frac{3\ln(2x-3)}{4}}}{x^2}dx\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$(2x-3)\left(\frac{d^2}{dx^2}y(x)\right)-x\left(\frac{d}{dx}y(x)\right)+y(x)=0$

- Highest derivative means the order of the ODE is 2

$\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

$\frac{d^2}{dx^2}y(x)=-\frac{y(x)}{2x-3}+\frac{\left(\frac{d}{dx}y(x)\right)x}{2x-3}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

$\frac{d^2}{dx^2}y(x)-\frac{\left(\frac{d}{dx}y(x)\right)x}{2x-3}+\frac{y(x)}{2x-3}=0$

☐ Check to see if $x_0=\frac{3}{2}$ is a regular singular point

◦ Define functions

$\left[P_2(x)=-\frac{x}{2x-3},P_3(x)=\frac{1}{2x-3}\right]$

◦ $\left(x-\frac{3}{2}\right)\cdot P_2(x)$ is analytic at $x=\frac{3}{2}$

$\left(\left(x-\frac{3}{2}\right)\cdot P_2(x)\right)\bigg|_{x=\frac{3}{2}}=-\frac{3}{4}$

◦ $\left(x-\frac{3}{2}\right)^2\cdot P_3(x)$ is analytic at $x=\frac{3}{2}$

$\left(\left(x-\frac{3}{2}\right)^2\cdot P_3(x)\right)\bigg|_{x=\frac{3}{2}}=0$

◦ $x=\frac{3}{2}$is a regular singular point

Check to see if $x_0=\frac{3}{2}$ is a regular singular point

$x_0=\frac{3}{2}$

- Multiply by denominators

$(2x-3)\left(\frac{d^2}{dx^2}y(x)\right)-x\left(\frac{d}{dx}y(x)\right)+y(x)=0$

- Change variables using $x=u+\frac{3}{2}$ so that the regular singular point is at $u=0$

$2u\left(\frac{d^2}{du^2}y(u)\right)+\left(-u-\frac{3}{2}\right)\left(\frac{d}{du}y(u)\right)+y(u)=0$

- Assume series solution for $y(u)$

$y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

☐ Rewrite ODE with series expansions

◦ Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$

$u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,u^{k+r-1+m}$

◦ Shift index using $k->k+1-m$

$u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,u^{k+r}$

◦ Convert $u\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion

$u\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,u^{k+r-1}$

◦ Shift index using $k->k+1$

$u\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=-1}^{\infty}a_{k+1}(k+1+r)\,(k+r)\,u^{k+r}$

Rewrite ODE with series expansions

$\frac{a_0r(-7+4r)u^{-1+r}}{2}+\left(\sum_{k=0}^{\infty}\left(\frac{a_{k+1}(k+1+r)(4k-3+4r)}{2}-a_k(k+r-1)\right)u^{k+r}\right)=0$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $\frac{r(-7+4r)}{2} = 0$
- Values of r that satisfy the indicial equation
  $r \in \left\{0, \frac{7}{4}\right\}$
- Each term in the series must be 0, giving the recursion relation
  $2\left(k+r-\frac{3}{4}\right)(k+1+r)\, a_{k+1} - a_k(k+r-1) = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+1} = \frac{2a_k(k+r-1)}{(4k-3+4r)(k+1+r)}$
- Recursion relation for $r = 0$; series terminates at $k = 1$
  $a_{k+1} = \frac{2a_k(k-1)}{(4k-3)(k+1)}$
- Apply recursion relation for $k = 0$
  $a_1 = \frac{2a_0}{3}$
- Terminating series solution of the ODE for $r = 0$. Use reduction of order to find the second linea
  $y(u) = a_0 \cdot \left(1 + \frac{2u}{3}\right)$
- Revert the change of variables $u = x - \frac{3}{2}$
  $\left[y(x) = \frac{2a_0x}{3}\right]$
- Recursion relation for $r = \frac{7}{4}$
  $a_{k+1} = \frac{2a_k\left(k+\frac{3}{4}\right)}{(4k+4)\left(k+\frac{11}{4}\right)}$
- Solution for $r = \frac{7}{4}$
  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+\frac{7}{4}}, a_{k+1} = \frac{2a_k\left(k+\frac{3}{4}\right)}{(4k+4)\left(k+\frac{11}{4}\right)}\right]$
- Revert the change of variables $u = x - \frac{3}{2}$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k \left(x-\frac{3}{2}\right)^{k+\frac{7}{4}}, a_{k+1} = \frac{2a_k\left(k+\frac{3}{4}\right)}{(4k+4)\left(k+\frac{11}{4}\right)}\right]$
- Combine solutions and rename parameters
  $\left[y(x) = \frac{2a_0x}{3} + \left(\sum_{k=0}^{\infty} b_k \left(x-\frac{3}{2}\right)^{k+\frac{7}{4}}\right), b_{k+1} = \frac{2b_k\left(k+\frac{3}{4}\right)}{(4k+4)\left(k+\frac{11}{4}\right)}\right]$

2.1.291 Problem 294

Internal problem ID [9463]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 294
Date solved : Monday, January 27, 2025 at 06:03:06 PM
CAS classification : [_Hermite]

Solve

$$y'' - xy' - 3y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.223 (sec)

Writing the ode as

$$y'' - xy' - 3y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -x \\ C &= -3 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 + 10}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2 + 10 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2}{4} + \frac{5}{2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.554: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 2 \\ &= -2 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x}{2} + \frac{5}{2x} - \frac{25}{4x^3} + \frac{125}{4x^5} - \frac{3125}{16x^7} + \frac{21875}{16x^9} - \frac{328125}{32x^{11}} + \frac{2578125}{32x^{13}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= \frac{x}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{x^2}{4}$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 + 10}{4} \\ &= Q + \frac{R}{4} \\ &= \left(\frac{x^2}{4} + \frac{5}{2}\right) + (0) \\ &= \frac{x^2}{4} + \frac{5}{2} \end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is $\frac{5}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(\frac{5}{2}\right) - (0) \\ &= \frac{5}{2} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{x}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{\frac{5}{2}}{\frac{1}{2}} - 1\right) &= 2 \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{\frac{5}{2}}{\frac{1}{2}} - 1\right) &= -3 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2}{4} + \frac{5}{2}$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-2	$\frac{x}{2}$	2	-3

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = 2$, and since there are no poles, then

$$
\begin{aligned}
d &= \alpha_\infty^+ \\
&= 2
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

Substituting the above values in the above results in

$$
\begin{aligned}
\omega &= (+)[\sqrt{r}]_\infty \\
&= 0 + \left(\frac{x}{2}\right) \\
&= \frac{x}{2} \\
&= \frac{x}{2}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 2$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = x^2 + a_1 x + a_0 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
\begin{aligned}
(2) + 2\left(\frac{x}{2}\right)(2x + a_1) + \left(\left(\frac{1}{2}\right) + \left(\frac{x}{2}\right)^2 - \left(\frac{x^2}{4} + \frac{5}{2}\right)\right) &= 0 \\
-a_1 x - 2a_0 + 2 &= 0
\end{aligned}
$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$
\{a_0 = 1, a_1 = 0\}
$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$
p(x) = x^2 + 1
$$

Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \left(x^2 + 1\right) e^{\int \frac{x}{2} dx} \\
&= \left(x^2 + 1\right) e^{\frac{x^2}{4}} \\
&= \left(x^2 + 1\right) e^{\frac{x^2}{4}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-x}{1} \, dx} \\
&= z_1 e^{\frac{x^2}{4}} \\
&= z_1 \left(e^{\frac{x^2}{4}}\right)
\end{aligned}
$$

Which simplifies to

$$y_1 = \mathrm{e}^{\frac{x^2}{2}} \left(x^2+1\right)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-x}{1}\, dx}}{\left(y_1\right)^2}\, dx \\
&= y_1 \int \frac{e^{\frac{x^2}{2}}}{\left(y_1\right)^2}\, dx \\
&= y_1 \left(\int \frac{\mathrm{e}^{-\frac{x^2}{2}}}{\left(x^2+1\right)^2} dx \right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{\frac{x^2}{2}} \left(x^2+1\right)\right) + c_2 \left(\mathrm{e}^{\frac{x^2}{2}} \left(x^2+1\right) \left(\int \frac{\mathrm{e}^{-\frac{x^2}{2}}}{\left(x^2+1\right)^2} dx \right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve
$\frac{d^2}{dx^2}y(x) - x\left(\frac{d}{dx}y(x)\right) - 3y(x) = 0$

- Highest derivative means the order of the ODE is 2
  $\frac{d^2}{dx^2}y(x)$
- Assume series solution for $y(x)$
  $y(x) = \sum_{k=0}^{\infty} a_k x^k$
- □ Rewrite DE with series expansions
  - Convert $x \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion
    $x \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k k\, x^k$
  - Convert $\frac{d^2}{dx^2}y(x)$ to series expansion
    $\frac{d^2}{dx^2}y(x) = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$
  - Shift index using $k- >k+2$
    $\frac{d^2}{dx^2}y(x) = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$

  Rewrite DE with series expansions
  $\sum_{k=0}^{\infty} \left(a_{k+2}(k+2)\,(k+1) - a_k(k+3)\right) x^k = 0$
- Each term in the series must be 0, giving the recursion relation
  $\left(k^2+3k+2\right) a_{k+2} - a_k(k+3) = 0$

- Recursion relation that defines the series solution to the ODE
$$\left[y(x)=\sum_{k=0}^{\infty} a_k x^k, a_{k+2}=\frac{a_k(k+3)}{k^2+3k+2}\right]$$

2.1.292 Problem 295

Internal problem ID [9464]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 295
Date solved : `Monday, January 27, 2025 at 06:03:06 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$\left(x^2+1\right)y''-xy'+y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.235 (sec)

Writing the ode as

$$\left(x^2+1\right)y''-xy'+y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=x^2+1\\B&=-x\\C&=1\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned}r&=\frac{s}{t}\\&=\frac{2AB'-2BA'+B^2-4AC}{4A^2}\end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r=\frac{-x^2-6}{4\left(x^2+1\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned}s&=-x^2-6\\t&=4\left(x^2+1\right)^2\end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{-x^2-6}{4\left(x^2+1\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.556: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^2 + 1)^2$. There is a pole at $x = i$ of order 2. There is a pole at $x = -i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{5}{16 (x - i)^2} + \frac{5}{16 (x + i)^2} + \frac{7i}{16 (x - i)} - \frac{7i}{16 (x + i)}$$

For the pole at $x = i$ let b be the coefficient of $\frac{1}{(x-i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{5}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{5}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{1}{4} \end{aligned}$$

For the pole at $x = -i$ let b be the coefficient of $\frac{1}{(x+i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{5}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{5}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{1}{4} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{-x^2 - 6}{4\left(x^2+1\right)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{1}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{-x^2 - 6}{4\left(x^2+1\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
i	2	0	$\frac{5}{4}$	$-\frac{1}{4}$
$-i$	2	0	$\frac{5}{4}$	$-\frac{1}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^-\right) \\
&= \frac{1}{2} - \left(-\frac{1}{2}\right) \\
&= 1
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2}\right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{1}{4\left(x-i\right)} - \frac{1}{4\left(x+i\right)} + (-)\left(0\right) \\
&= -\frac{1}{4\left(x-i\right)} - \frac{1}{4\left(x+i\right)} \\
&= -\frac{x}{2x^2+2}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{4(x-i)} - \frac{1}{4(x+i)}\right)(1) + \left(\left(\frac{1}{4(x-i)^2} + \frac{1}{4(x+i)^2}\right) + \left(-\frac{1}{4(x-i)} - \frac{1}{4(x+i)}\right)^2 - \left(\frac{-}{4(\ldots}\right.\right.$$

$$\frac{(x^2+1\ldots}{(-x+i)^2(\ldots}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \,dx} \\
&= (x)\, e^{\int \left(-\frac{1}{4(x-i)} - \frac{1}{4(x+i)}\right) dx} \\
&= (x) \frac{1}{((-x+i)(x+i))^{1/4}} \\
&= \frac{x}{(-x^2-1)^{1/4}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-x}{x^2+1} \,dx} \\
&= z_1 e^{\frac{\ln(x^2+1)}{4}} \\
&= z_1\left((x^2+1)^{1/4}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \left(\frac{1}{2} - \frac{i}{2}\right) x\sqrt{2}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \,dx}}{y_1^2} \,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-x}{x^2+1} \,dx}}{(y_1)^2} \,dx \\
&= y_1 \int \frac{e^{\frac{\ln(x^2+1)}{2}}}{(y_1)^2} \,dx \\
&= y_1 \left(i\left(-\frac{(x^2+1)^{3/2}}{x} + x\sqrt{x^2+1} + \operatorname{arcsinh}(x)\right)\right)
\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\left(\frac{1}{2} - \frac{i}{2} \right) x\sqrt{2} \right) + c_2 \left(\left(\frac{1}{2} - \frac{i}{2} \right) x\sqrt{2} \left(i \left(-\frac{(x^2+1)^{3/2}}{x} + x\sqrt{x^2+1} + \operatorname{arcsinh}(x) \right) \right) \right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

2.1.293 Problem 296

Internal problem ID [9465]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 296
Date solved : Monday, January 27, 2025 at 06:03:07 PM
CAS classification : [_Hermite]

Solve

$$y'' - xy' + 2y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.241 (sec)

Writing the ode as

$$y'' - xy' + 2y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -x \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 - 10}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2 - 10 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2}{4} - \frac{5}{2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.557: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 2 \\ &= -2 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x}{2} - \frac{5}{2x} - \frac{25}{4x^3} - \frac{125}{4x^5} - \frac{3125}{16x^7} - \frac{21875}{16x^9} - \frac{328125}{32x^{11}} - \frac{2578125}{32x^{13}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 1$ gives

$$[\sqrt{r}]_\infty = \sum_{i=0}^{1} a_i x^i = \frac{x}{2} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{x^2}{4}$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 - 10}{4} \\ &= Q + \frac{R}{4} \\ &= \left(\frac{x^2}{4} - \frac{5}{2}\right) + (0) \\ &= \frac{x^2}{4} - \frac{5}{2} \end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is $-\frac{5}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{5}{2}\right) - (0) \\ &= -\frac{5}{2} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{x}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) = \frac{1}{2}\left(\frac{-\frac{5}{2}}{\frac{1}{2}} - 1\right) = -3 \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) = \frac{1}{2}\left(-\frac{-\frac{5}{2}}{\frac{1}{2}} - 1\right) = 2 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2}{4} - \frac{5}{2}$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-2	$\frac{x}{2}$	-3	2

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 2$, and since there are no poles then

$$\begin{aligned} d &= \alpha_\infty^- \\ &= 2 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= (-)[\sqrt{r}]_\infty \\ &= 0 + (-)\left(\frac{x}{2}\right) \\ &= -\frac{x}{2} \\ &= -\frac{x}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 2$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = x^2 + a_1 x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (2) + 2\left(-\frac{x}{2}\right)(2x + a_1) + \left(\left(-\frac{1}{2}\right) + \left(-\frac{x}{2}\right)^2 - \left(\frac{x^2}{4} - \frac{5}{2}\right)\right) &= 0 \\ a_1 x + 2a_0 + 2 &= 0 \end{aligned}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = -1, a_1 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^2 - 1$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega\, dx} \\ &= (x^2 - 1)\, e^{\int -\frac{x}{2} dx} \\ &= (x^2 - 1)\, e^{-\frac{x^2}{4}} \\ &= (x^2 - 1)\, e^{-\frac{x^2}{4}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-x}{1}\, dx} \\ &= z_1 e^{\frac{x^2}{4}} \\ &= z_1\left(e^{\frac{x^2}{4}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = x^2 - 1$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-x}{1}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{\frac{x^2}{2}}}{(y_1)^2}\, dx \\ &= y_1 \left(\int \frac{e^{\frac{x^2}{2}}}{(x^2-1)^2} dx \right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 (x^2 - 1) + c_2 \left(x^2 - 1 \left(\int \frac{e^{\frac{x^2}{2}}}{(x^2-1)^2} dx \right) \right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve
$\frac{d^2}{dx^2}y(x) - x\left(\frac{d}{dx}y(x)\right) + 2y(x) = 0$

- Highest derivative means the order of the ODE is 2
  $\frac{d^2}{dx^2}y(x)$
- Assume series solution for $y(x)$
  $y(x) = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite DE with series expansions
  - Convert $x \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion
    $x \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k k\, x^k$
  - Convert $\frac{d^2}{dx^2}y(x)$ to series expansion
    $\frac{d^2}{dx^2}y(x) = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$
  - Shift index using $k- >k+2$
    $\frac{d^2}{dx^2}y(x) = \sum_{k=0}^{\infty} a_{k+2}(k+2)(k+1)\, x^k$

  Rewrite DE with series expansions
  $\sum_{k=0}^{\infty} \left(a_{k+2}(k+2)(k+1) - a_k(k-2)\right) x^k = 0$

- Each term in the series must be 0, giving the recursion relation
  $(k^2 + 3k + 2)\, a_{k+2} - a_k(k-2) = 0$
- Recursion relation; series terminates at $k = 2$

$a_{k+2} = \frac{a_k(k-2)}{k^2+3k+2}$

- Apply recursion relation for $k = 0$

  $a_2 = -a_0$

- Terminating series solution of the ODE. Use reduction of order to find the second linearly indepe

  $y(x) = A_2x^2 + A_1x - a_0$

2.1.294 Problem 297

Internal problem ID [9466]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 297
Date solved : `Monday, January 27, 2025 at 06:03:07 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$\left(-x^2+1\right) y''-y'+y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.667 (sec)

Writing the ode as

$$\left(-x^2+1\right) y''-y'+y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A&=-x^2+1\\ B&=-1\\ C&=1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r&=\frac{s}{t}\\ &=\frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{4x^2-4x-3}{4\left(x^2-1\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s&=4x^2-4x-3\\ t&=4\left(x^2-1\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{4x^2-4x-3}{4\left(x^2-1\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.559: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^2-1)^2$. There is a pole at $x = 1$ of order 2. There is a pole at $x = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Unable to find solution using case one

Attempting to find a solution using case $n = 2$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{3}{16\,(x-1)^2} + \frac{5}{16\,(x+1)^2} - \frac{7}{16\,(x+1)} + \frac{7}{16\,(x-1)}$$

For the pole at $x = 1$ let b be the coefficient of $\frac{1}{(x-1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} E_c &= \{2, 2 + 2\sqrt{1+4b}, 2 - 2\sqrt{1+4b}\} \\ &= \{1, 2, 3\} \end{aligned}$$

For the pole at $x = -1$ let b be the coefficient of $\frac{1}{(x+1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{5}{16}$. Hence

$$\begin{aligned} E_c &= \{2, 2 + 2\sqrt{1+4b}, 2 - 2\sqrt{1+4b}\} \\ &= \{-1, 2, 5\} \end{aligned}$$

Since the order of r at ∞ is 2 then let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{4x^2 - 4x - 3}{4\left(x^2 - 1\right)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = 1$. Hence

$$\begin{aligned} E_\infty &= \{2, 2 + 2\sqrt{1+4b}, 2 - 2\sqrt{1+4b}\} \\ &= \{2\} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ for case 2 of Kovacic algorithm.

pole c location	pole order	E_c
1	2	$\{1, 2, 3\}$
-1	2	$\{-1, 2, 5\}$

Order of r at ∞	E_∞
2	$\{2\}$

Using the family $\{e_1, e_2, \dots, e_\infty\}$ given by

$$e_1 = 1,\ e_2 = -1,\ e_\infty = 2$$

Gives a non negative integer d (the degree of the polynomial $p(x)$), which is generated using

$$\begin{aligned} d &= \frac{1}{2}\left(e_\infty - \sum_{c\in\Gamma} e_c\right) \\ &= \frac{1}{2}(2 - (1 + (-1))) \\ &= 1 \end{aligned}$$

We now form the following rational function

$$\begin{aligned} \theta &= \frac{1}{2}\sum_{c\in\Gamma} \frac{e_c}{x - c} \\ &= \frac{1}{2}\left(\frac{1}{(x - (1))} + \frac{-1}{(x - (-1))}\right) \\ &= \frac{1}{2x - 2} - \frac{1}{2(x+1)} \end{aligned}$$

Now we search for a monic polynomial $p(x)$ of degree $d = 1$ such that

$$p''' + 3\theta p'' + \left(3\theta^2 + 3\theta' - 4r\right)p' + \left(\theta'' + 3\theta\theta' + \theta^3 - 4r\theta - 2r'\right)p = 0 \tag{1A}$$

Since $d = 1$, then letting

$$p = x + a_0 \tag{2A}$$

Substituting p and θ into Eq. (1A) gives

$$\frac{4a_0 - 6}{(x+1)^2 (x-1)} = 0$$

And solving for p gives

$$p = x + \frac{3}{2}$$

Now that $p(x)$ is found let

$$\begin{aligned}\phi &= \theta + \frac{p'}{p}\\ &= \frac{1}{x+\frac{3}{2}} + \frac{1}{2x-2} - \frac{1}{2(x+1)}\end{aligned}$$

Let ω be the solution of

$$\omega^2 - \phi\omega + \left(\frac{1}{2}\phi' + \frac{1}{2}\phi^2 - r\right) = 0$$

Substituting the values for ϕ and r into the above equation gives

$$w^2 - \left(\frac{1}{x+\frac{3}{2}} + \frac{1}{2x-2} - \frac{1}{2(x+1)}\right)w + \frac{-8x^3-4x^2+10x+7}{4(x^2-1)^2(2x+3)} = 0$$

Solving for ω gives

$$\omega = \frac{2\sqrt{5}\,\sqrt{(x-1)(x+1)}\,x + 2\sqrt{5}\,\sqrt{(x-1)(x+1)} + 2x^2+2x+1}{2(2x+3)(x-1)(x+1)}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}z_1(x) &= e^{\int \omega\,dx}\\ &= e^{\int \frac{2\sqrt{5}\,\sqrt{(x-1)(x+1)}\,x+2\sqrt{5}\,\sqrt{(x-1)(x+1)}+2x^2+2x+1}{2(2x+3)(x-1)(x+1)}dx}\\ &= \frac{\sqrt{2x+3}\,(x-1)^{1/4}\left(x+\sqrt{x^2-1}\right)^{\frac{\sqrt{5}}{2}} 5^{1/4}}{(x+1)^{1/4}\sqrt{\frac{5\sqrt{x^2-1}+(2+3x)\sqrt{5}}{\sqrt{x^2-1}\sqrt{-\frac{(2x+3)^2}{x^2-1}}}}}\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}\\ &= z_1 e^{-\int \frac{1}{2}\frac{-1}{-x^2+1}\,dx}\\ &= z_1 e^{\frac{\operatorname{arctanh}(x)}{2}}\\ &= z_1\left(\sqrt{\frac{x+1}{\sqrt{-x^2+1}}}\right)\end{aligned}$$

Which simplifies to

$$y_1 = \frac{\sqrt{\frac{x+1}{\sqrt{-x^2+1}}}\left(x+\sqrt{x^2-1}\right)^{\frac{\sqrt{5}}{2}}\sqrt{2x+3}\,(5x-5)^{1/4}}{\sqrt{\frac{i\left(3\sqrt{5}\,x+5\sqrt{x^2-1}+2\sqrt{5}\right)}{2x+3}}\,(x+1)^{1/4}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}y_2 &= y_1 \int \frac{e^{\int -\frac{-1}{-x^2+1}\,dx}}{(y_1)^2}\,dx\\ &= y_1 \int \frac{e^{\operatorname{arctanh}(x)}}{(y_1)^2}\,dx\\ &= y_1\left(\int \frac{i\sqrt{x+1}\left(x+\sqrt{x^2-1}\right)^{-\sqrt{5}}\left(3\sqrt{5}\,x+5\sqrt{x^2-1}+2\sqrt{5}\right)}{(2x+3)^2\sqrt{5x-5}}dx\right)\end{aligned}$$

Therefore the solution is

$$y = c_1y_1 + c_2y_2$$

$$= c_1\left(\frac{\sqrt{\frac{x+1}{\sqrt{-x^2+1}}}\left(x+\sqrt{x^2-1}\right)^{\frac{\sqrt{5}}{2}}\sqrt{2x+3}\,(5x-5)^{1/4}}{\sqrt{\frac{i\left(3\sqrt{5}\,x+5\sqrt{x^2-1}+2\sqrt{5}\right)}{2x+3}}\,(x+1)^{1/4}}\right)$$

$$+c_2\left(\frac{\sqrt{\frac{x+1}{\sqrt{-x^2+1}}}\left(x+\sqrt{x^2-1}\right)^{\frac{\sqrt{5}}{2}}\sqrt{2x+3}\,(5x-5)^{1/4}}{\sqrt{\frac{i\left(3\sqrt{5}\,x+5\sqrt{x^2-1}+2\sqrt{5}\right)}{2x+3}}\,(x+1)^{1/4}}\left(\int \frac{i\sqrt{x+1}\left(x+\sqrt{x^2-1}\right)^{-\sqrt{5}}\left(3\sqrt{5}\,x+5\sqrt{x^2}\right.}{(2x+3)^2\sqrt{5x-5}}\right.\right.$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$(-x^2+1)\left(\frac{d^2}{dx^2}y(x)\right) - \frac{d}{dx}y(x) + y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = \frac{y(x)}{x^2-1} - \frac{\frac{d}{dx}y(x)}{x^2-1}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x) + \frac{\frac{d}{dx}y(x)}{x^2-1} - \frac{y(x)}{x^2-1} = 0$

☐ Check to see if x_0 is a regular singular point

  - Define functions

    $\left[P_2(x) = \frac{1}{x^2-1}, P_3(x) = -\frac{1}{x^2-1}\right]$

  - $(x+1)\cdot P_2(x)$ is analytic at $x=-1$

    $\left((x+1)\cdot P_2(x)\right)\bigg|_{x=-1} = -\frac{1}{2}$

  - $(x+1)^2\cdot P_3(x)$ is analytic at $x=-1$

    $\left((x+1)^2\cdot P_3(x)\right)\bigg|_{x=-1} = 0$

  - $x=-1$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = -1$

- Multiply by denominators

  $(x^2-1)\left(\frac{d^2}{dx^2}y(x)\right) + \frac{d}{dx}y(x) - y(x) = 0$

- Change variables using $x = u-1$ so that the regular singular point is at $u=0$

  $(u^2-2u)\left(\frac{d^2}{du^2}y(u)\right) + \frac{d}{du}y(u) - y(u) = 0$

- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

☐ Rewrite ODE with series expansions

  - Convert $\frac{d}{du}y(u)$ to series expansion

    $\frac{d}{du}y(u) = \sum_{k=0}^{\infty} a_k(k+r)\,u^{k+r-1}$

  - Shift index using $k->k+1$

$\frac{d}{du}y(u) = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\, u^{k+r}$

- Convert $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m = 1..2$

  $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, u^{k+r-2+m}$

- Shift index using $k- > k+2-m$

  $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, u^{k+r}$

  Rewrite ODE with series expansions

  $-a_0 r(-3+2r)\, u^{-1+r} + \left(\sum_{k=0}^{\infty} \left(-a_{k+1}(k+1+r)\,(2k-1+2r) + a_k(k^2+2kr+r^2-k-r-1)\right) u^{k+}\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $-r(-3+2r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \left\{0, \frac{3}{2}\right\}$

- Each term in the series must be 0, giving the recursion relation

  $-2(k+1+r)\left(k+r-\frac{1}{2}\right) a_{k+1} + \left(k^2+(2r-1)\, k+r^2-r-1\right) a_k = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+1} = \frac{(k^2+2kr+r^2-k-r-1)a_k}{(k+1+r)(2k-1+2r)}$

- Recursion relation for $r = 0$

  $a_{k+1} = \frac{(k^2-k-1)a_k}{(k+1)(2k-1)}$

- Solution for $r = 0$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+1} = \frac{(k^2-k-1)a_k}{(k+1)(2k-1)}\right]$

- Revert the change of variables $u = x+1$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k(x+1)^k, a_{k+1} = \frac{(k^2-k-1)a_k}{(k+1)(2k-1)}\right]$

- Recursion relation for $r = \frac{3}{2}$

  $a_{k+1} = \frac{(k^2+2k-\frac{1}{4})a_k}{(k+\frac{5}{2})(2k+2)}$

- Solution for $r = \frac{3}{2}$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+\frac{3}{2}}, a_{k+1} = \frac{(k^2+2k-\frac{1}{4})a_k}{(k+\frac{5}{2})(2k+2)}\right]$

- Revert the change of variables $u = x+1$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k(x+1)^{k+\frac{3}{2}}, a_{k+1} = \frac{(k^2+2k-\frac{1}{4})a_k}{(k+\frac{5}{2})(2k+2)}\right]$

- Combine solutions and rename parameters

  $\left[y(x) = \left(\sum_{k=0}^{\infty} a_k(x+1)^k\right) + \left(\sum_{k=0}^{\infty} b_k(x+1)^{k+\frac{3}{2}}\right), a_{k+1} = \frac{(k^2-k-1)a_k}{(k+1)(2k-1)}, b_{k+1} = \frac{(k^2+2k-\frac{1}{4})b_k}{(k+\frac{5}{2})(2k+2)}\right]$

2.1.295 Problem 298

Internal problem ID [9467]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 298
Date solved : `Monday, January 27, 2025 at 06:03:09 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x(x+1)^2 y'' + \left(-x^2+1\right) y' + (x-1) y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.161 (sec)

Writing the ode as

$$x(x+1)^2 y'' + \left(-x^2+1\right) y' + (x-1) y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x(x+1)^2 \\ B &= -x^2+1 \\ C &= x-1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{1}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.561: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = -\frac{1}{4x^2}$$

Since the gcd$(s,t)=1$. This gives $b=-\frac{1}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= \frac{1}{2}+\sqrt{1+4b}=\frac{1}{2} \\
\alpha_\infty^{-} &= \frac{1}{2}-\sqrt{1+4b}=\frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r=-\frac{1}{4x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-}=\frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^{-}-\left(\alpha_{c_1}^{-}\right) \\
&= \frac{1}{2}-\left(\frac{1}{2}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$
\omega=\sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c+\frac{\alpha_c^{s(c)}}{x-c}\right)+s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1}+\frac{\alpha_{c_1}^{-}}{x-c_1}\right)+(-)[\sqrt{r}]_\infty \\
&= \frac{1}{2x}+(-)(0) \\
&= \frac{1}{2x} \\
&= \frac{1}{2x}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p''+2\omega p'+\left(\omega'+\omega^2-r\right)p=0 \tag{1A}
$$

Let

$$
p(x)=1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{2x}\right)(0) + \left(\left(-\frac{1}{2x^2}\right) + \left(\frac{1}{2x}\right)^2 - \left(-\frac{1}{4x^2}\right)\right) = 0$$
$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= pe^{\int \omega \, dx} \\ &= e^{\int \frac{1}{2x} dx} \\ &= \sqrt{x} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-x^2+1}{x(x+1)^2} \, dx} \\ &= z_1 e^{-\frac{\ln(x)}{2}+\ln(x+1)} \\ &= z_1 \left(\frac{x+1}{\sqrt{x}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = x + 1$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-x^2+1}{x(x+1)^2} \, dx}}{(y_1)^2} \, dx \\ &= y_1 \int \frac{e^{-\ln(x)+2\ln(x+1)}}{(y_1)^2} \, dx \\ &= y_1(\ln(x)) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(x+1) + c_2(x + 1(\ln(x))) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x(x+1)^2 \left(\frac{d^2}{dx^2}y(x)\right) + (-x^2+1)\left(\frac{d}{dx}y(x)\right) + (x-1)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{(x-1)y(x)}{x(x+1)^2} + \frac{(x-1)\left(\frac{d}{dx}y(x)\right)}{x(x+1)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x) - \frac{(x-1)\left(\frac{d}{dx}y(x)\right)}{x(x+1)} + \frac{(x-1)y(x)}{x(x+1)^2} = 0$

□ Check to see if x_0 is a regular singular point

  - Define functions

    $\left[P_2(x) = -\frac{x-1}{x(x+1)}, P_3(x) = \frac{x-1}{x(x+1)^2}\right]$

  - $(x+1)\cdot P_2(x)$ is analytic at $x=-1$

    $\left((x+1)\cdot P_2(x)\right)\Big|_{x=-1} = -2$

  - $(x+1)^2\cdot P_3(x)$ is analytic at $x=-1$

    $\left((x+1)^2\cdot P_3(x)\right)\Big|_{x=-1} = 2$

  - $x=-1$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = -1$

- Multiply by denominators

  $x(x+1)^2 \left(\frac{d^2}{dx^2}y(x)\right) - (x-1)(x+1)\left(\frac{d}{dx}y(x)\right) + (x-1)\,y(x) = 0$

- Change variables using $x = u-1$ so that the regular singular point is at $u=0$

  $(u^3-u^2)\left(\frac{d^2}{du^2}y(u)\right) + (-u^2+2u)\left(\frac{d}{du}y(u)\right) + (u-2)\,y(u) = 0$

- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

□ Rewrite ODE with series expansions

  - Convert $u^m\cdot y(u)$ to series expansion for $m = 0..1$

    $u^m\cdot y(u) = \sum_{k=0}^{\infty} a_k u^{k+r+m}$

  - Shift index using $k->k-m$

    $u^m\cdot y(u) = \sum_{k=m}^{\infty} a_{k-m} u^{k+r}$

  - Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 1..2$

    $u^m\cdot\left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,u^{k+r-1+m}$

  - Shift index using $k->k+1-m$

    $u^m\cdot\left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,u^{k+r}$

  - Convert $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m = 2..3$

    $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\,u^{k+r-2+m}$

  - Shift index using $k->k+2-m$

$$u^{m}\cdot\left(\frac{d^{2}}{du^{2}}y(u)\right)=\sum_{k=-2+m}^{\infty}a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,u^{k+r}$$

Rewrite ODE with series expansions

$$-a_{0}(-1+r)\,(-2+r)\,u^{r}+\left(\sum_{k=1}^{\infty}\left(-a_{k}(k+r-1)\,(k+r-2)+a_{k-1}(k+r-2)^{2}\right)u^{k+r}\right)=0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $-(-1+r)\,(-2+r)=0$
- Values of r that satisfy the indicial equation

  $r\in\{1,2\}$
- Each term in the series must be 0, giving the recursion relation

  $-a_{k}(k+r-1)\,(k+r-2)+a_{k-1}(k+r-2)^{2}=0$

2.1.296 Problem 299

Internal problem ID [9468]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 299
Date solved : `Monday, January 27, 2025 at 06:03:09 PM`
CAS classification : `[[_Emden, _Fowler]]`

Solve

$$2xy'' - y' + 2y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.201 (sec)

Writing the ode as

$$2xy'' - y' + 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2x \\ B &= -1 \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{5 - 16x}{16x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 5 - 16x \\ t &= 16x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{5 - 16x}{16x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.563: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 1 \\ &= 1 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16x^2$. There is a pole at $x = 0$ of order 2. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [2]$$

Attempting to find a solution using case $n = 2$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{x} + \frac{5}{16x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{5}{16}$. Hence

$$\begin{aligned} E_c &= \{2, 2 + 2\sqrt{1+4b}, 2 - 2\sqrt{1+4b}\} \\ &= \{-1, 2, 5\} \end{aligned}$$

Since the order of r at ∞ is $1 < 2$ then

$$E_\infty = \{1\}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ for case 2 of Kovacic algorithm.

pole c location	pole order	E_c
0	2	$\{-1,2,5\}$

Order of r at ∞	E_∞
1	$\{1\}$

Using the family $\{e_1, e_2, \dots, e_\infty\}$ given by

$$e_1 = -1, \; e_\infty = 1$$

Gives a non negative integer d (the degree of the polynomial $p(x)$), which is generated using

$$\begin{aligned} d &= \frac{1}{2}\left(e_\infty - \sum_{c\in\Gamma} e_c\right) \\ &= \frac{1}{2}(1-(-1)) \\ &= 1 \end{aligned}$$

We now form the following rational function

$$\begin{aligned} \theta &= \frac{1}{2}\sum_{c\in\Gamma} \frac{e_c}{x-c} \\ &= \frac{1}{2}\left(\frac{-1}{(x-(0))}\right) \\ &= -\frac{1}{2x} \end{aligned}$$

Now we search for a monic polynomial $p(x)$ of degree $d = 1$ such that

$$p''' + 3\theta p'' + \left(3\theta^2 + 3\theta' - 4r\right)p' + \left(\theta'' + 3\theta\theta' + \theta^3 - 4r\theta - 2r'\right)p = 0 \tag{1A}$$

Since $d = 1$, then letting

$$p = x + a_0 \tag{2A}$$

Substituting p and θ into Eq. (1A) gives

$$\frac{1-4a_0}{x^2} = 0$$

And solving for p gives

$$p = x + \frac{1}{4}$$

Now that $p(x)$ is found let

$$\begin{aligned} \phi &= \theta + \frac{p'}{p} \\ &= \frac{1}{x+\frac{1}{4}} - \frac{1}{2x} \end{aligned}$$

Let ω be the solution of

$$\omega^2 - \phi\omega + \left(\frac{1}{2}\phi' + \frac{1}{2}\phi^2 - r\right) = 0$$

Substituting the values for ϕ and r into the above equation gives

$$w^2 - \left(\frac{1}{x+\frac{1}{4}} - \frac{1}{2x}\right)w + \frac{64x^2 - 12x + 1}{64x^3 + 16x^2} = 0$$

Solving for ω gives

$$\omega = \frac{16x\sqrt{-x} + 4x - 1}{4\,(4x+1)\,x}$$

Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \frac{16x\sqrt{-x}+4x-1}{4(4x+1)x} dx} \\
&= \frac{\left(2\sqrt{-x}-1\right) \mathrm{e}^{2\sqrt{-x}}}{\left(-x\right)^{1/4}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-1}{2x} \, dx} \\
&= z_1 e^{\frac{\ln(x)}{4}} \\
&= z_1 \left(x^{1/4}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{x^{1/4}\left(2\sqrt{-x}-1\right) \mathrm{e}^{2\sqrt{-x}}}{\left(-x\right)^{1/4}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-1}{2x} \, dx}}{\left(y_1\right)^2} \, dx \\
&= y_1 \int \frac{e^{\frac{\ln(x)}{2}}}{\left(y_1\right)^2} \, dx \\
&= y_1 \left(\frac{\mathrm{e}^{-4\sqrt{-x}}}{8} + \frac{\mathrm{e}^{-4\sqrt{-x}}}{8\sqrt{-x}-4}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{x^{1/4}\left(2\sqrt{-x}-1\right) \mathrm{e}^{2\sqrt{-x}}}{\left(-x\right)^{1/4}}\right) + c_2 \left(\frac{x^{1/4}\left(2\sqrt{-x}-1\right) \mathrm{e}^{2\sqrt{-x}}}{\left(-x\right)^{1/4}} \left(\frac{\mathrm{e}^{-4\sqrt{-x}}}{8} + \frac{\mathrm{e}^{-4\sqrt{-x}}}{8\sqrt{-x}-4}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$2\left(\frac{d^2}{dx^2}y(x)\right)x-\frac{d}{dx}y(x)+2y(x)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x)=-\frac{y(x)}{x}+\frac{\frac{d}{dx}y(x)}{2x}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x)-\frac{\frac{d}{dx}y(x)}{2x}+\frac{y(x)}{x}=0$

□ Check to see if $x_0=0$ is a regular singular point

  - Define functions

    $\left[P_2(x)=-\frac{1}{2x},P_3(x)=\frac{1}{x}\right]$

  - $x\cdot P_2(x)$ is analytic at $x=0$

    $\left(x\cdot P_2(x)\right)\bigg|_{x=0}=-\frac{1}{2}$

  - $x^2\cdot P_3(x)$ is analytic at $x=0$

    $\left(x^2\cdot P_3(x)\right)\bigg|_{x=0}=0$

  - $x=0$is a regular singular point

  Check to see if $x_0=0$ is a regular singular point

  $x_0=0$

- Multiply by denominators

  $2\left(\frac{d^2}{dx^2}y(x)\right)x-\frac{d}{dx}y(x)+2y(x)=0$

- Assume series solution for $y(x)$

  $y(x)=\sum_{k=0}^{\infty}a_kx^{k+r}$

□ Rewrite ODE with series expansions

  - Convert $\frac{d}{dx}y(x)$ to series expansion

    $\frac{d}{dx}y(x)=\sum_{k=0}^{\infty}a_k(k+r)\,x^{k+r-1}$

  - Shift index using $k->k+1$

    $\frac{d}{dx}y(x)=\sum_{k=-1}^{\infty}a_{k+1}(k+1+r)\,x^{k+r}$

  - Convert $x\cdot\left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

    $x\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,x^{k+r-1}$

  - Shift index using $k->k+1$

    $x\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=-1}^{\infty}a_{k+1}(k+1+r)\,(k+r)\,x^{k+r}$

  Rewrite ODE with series expansions

  $a_0r(-3+2r)\,x^{-1+r}+\left(\sum_{k=0}^{\infty}\left(a_{k+1}(k+1+r)\,(2k-1+2r)+2a_k\right)x^{k+r}\right)=0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r(-3+2r)=0$

- Values of r that satisfy the indicial equation

  $r\in\left\{0,\frac{3}{2}\right\}$

- Each term in the series must be 0, giving the recursion relation
  $2(k+1+r)\left(k+r-\frac{1}{2}\right)a_{k+1}+2a_k=0$
- Recursion relation that defines series solution to ODE
  $a_{k+1}=-\frac{2a_k}{(k+1+r)(2k-1+2r)}$
- Recursion relation for $r=0$
  $a_{k+1}=-\frac{2a_k}{(k+1)(2k-1)}$
- Solution for $r=0$
  $\left[y(x)=\sum_{k=0}^{\infty}a_k x^k, a_{k+1}=-\frac{2a_k}{(k+1)(2k-1)}\right]$
- Recursion relation for $r=\frac{3}{2}$
  $a_{k+1}=-\frac{2a_k}{\left(k+\frac{5}{2}\right)(2k+2)}$
- Solution for $r=\frac{3}{2}$
  $\left[y(x)=\sum_{k=0}^{\infty}a_k x^{k+\frac{3}{2}}, a_{k+1}=-\frac{2a_k}{\left(k+\frac{5}{2}\right)(2k+2)}\right]$
- Combine solutions and rename parameters
  $\left[y(x)=\left(\sum_{k=0}^{\infty}a_k x^k\right)+\left(\sum_{k=0}^{\infty}b_k x^{k+\frac{3}{2}}\right), a_{k+1}=-\frac{2a_k}{(k+1)(2k-1)}, b_{k+1}=-\frac{2b_k}{\left(k+\frac{5}{2}\right)(2k+2)}\right]$

Date solved : `Monday, January 27, 2025 at 06:03:10 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$xy'' + xy' - 2y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.220 (sec)

Writing the ode as

$$xy'' + xy' - 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x \\ B &= x \\ C &= -2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x+8}{4x} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x + 8 \\ t &= 4x \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x+8}{4x}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.565: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 1 - 1 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x$. There is a pole at $x = 0$ of order 1. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 1. For the pole at $x = 0$ of order 1 then

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= 1 \\ \alpha_c^- &= 1 \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} + \frac{2}{x} - \frac{4}{x^2} + \frac{16}{x^3} - \frac{80}{x^4} + \frac{448}{x^5} - \frac{2688}{x^6} + \frac{16896}{x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x+8}{4x} \\ &= Q + \frac{R}{4x} \\ &= \left(\frac{1}{4}\right) + \left(\frac{2}{x}\right) \\ &= \frac{1}{4} + \frac{2}{x} \end{aligned}$$

Since the degree of t is 1, then we see that the coefficient of the term 1 in the remainder R is 8. Dividing this by leading coefficient in t which is 4 gives 2. Now b can be found.

$$\begin{aligned} b &= (2) - (0) \\ &= 2 \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{2}{\frac{1}{2}} - 0\right) &&= 2 \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{2}{\frac{1}{2}} - 0\right) &&= -2 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x+8}{4x}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	1	0	0	1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	2	-2

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = 2$ then

$$\begin{aligned} d &= \alpha_\infty^+ - (\alpha_{c_1}^-) \\ &= 2 - (1) \\ &= 1 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (+)[\sqrt{r}]_\infty \\ &= \frac{1}{x} + \left(\frac{1}{2}\right) \\ &= \frac{1}{x} + \frac{1}{2} \\ &= \frac{1}{x} + \frac{1}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r) p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{x} + \frac{1}{2}\right)(1) + \left(\left(-\frac{1}{x^2}\right) + \left(\frac{1}{x} + \frac{1}{2}\right)^2 - \left(\frac{x+8}{4x}\right) \right) = 0$$

$$\frac{2-a_0}{x} = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 2\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = 2 + x$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= (2+x)\, e^{\int \left(\frac{1}{x}+\frac{1}{2}\right) dx} \\ &= (2+x)\, e^{\frac{x}{2}+\ln(x)} \\ &= (2+x)\, x\, e^{\frac{x}{2}} \end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{x}{x}\,dx} \\
&= z_1 e^{-\frac{x}{2}} \\
&= z_1\left(\mathrm{e}^{-\frac{x}{2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = (2+x)\,x
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x}{x}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-x}}{(y_1)^2}\,dx \\
&= y_1\left(-\frac{\mathrm{e}^{-x}}{4x} + \frac{\mathrm{Ei}_1(x)}{2} + \frac{\mathrm{e}^{-x}}{-8-4x}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1((2+x)\,x) + c_2\left((2+x)\,x\left(-\frac{\mathrm{e}^{-x}}{4x} + \frac{\mathrm{Ei}_1(x)}{2} + \frac{\mathrm{e}^{-x}}{-8-4x}\right)\right)
\end{aligned}
$$

2.1.298 Problem 301

Internal problem ID [9470]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 301
Date solved : `Monday, January 27, 2025 at 06:03:10 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x(x-1)^2 y''-2y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.151 (sec)

Writing the ode as

$$x(x-1)^2 y''-2y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A&=x(x-1)^2\\ B&=0\\ C&=-2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r&=\frac{s}{t}\\ &=\frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{2}{x\left(x-1\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s&=2\\ t&=x(x-1)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{2}{x\left(x-1\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.566: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 3 - 0 \\ &= 3 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = x(x-1)^2$. There is a pole at $x = 0$ of order 1. There is a pole at $x = 1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 3 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 3 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 1. For the pole at $x = 0$ of order 1 then

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= 1 \\ \alpha_c^- &= 1 \end{aligned}$$

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{2}{x-1} + \frac{2}{(x-1)^2} + \frac{2}{x}$$

For the pole at $x = 1$ let b be the coefficient of $\frac{1}{(x-1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1 \end{aligned}$$

Since the order of r at ∞ is $3>2$ then

$$\begin{aligned}[\sqrt{r}]_\infty &= 0\\ \alpha_\infty^+ &= 0\\ \alpha_\infty^- &= 1\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{2}{x(x-1)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	1	0	0	1
1	2	0	2	-1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
3	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+=0$ then

$$\begin{aligned}d &= \alpha_\infty^+ - \left(\alpha_{c_1}^- + \alpha_{c_2}^-\right)\\ &= 0-(0)\\ &= 0\end{aligned}$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2}\right) + (+)[\sqrt{r}]_\infty\\ &= \frac{1}{x} - \frac{1}{x-1} + (0)\\ &= \frac{1}{x} - \frac{1}{x-1}\\ &= -\frac{1}{x(x-1)}\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{x} - \frac{1}{x-1}\right)(0) + \left(\left(-\frac{1}{x^2} + \frac{1}{(x-1)^2}\right) + \left(\frac{1}{x} - \frac{1}{x-1}\right)^2 - \left(\frac{2}{x(x-1)^2}\right)\right) = 0$$
$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= e^{\int \left(\frac{1}{x} - \frac{1}{x-1}\right) dx} \\ &= \frac{x}{x-1} \end{aligned}$$

The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \frac{x}{x-1} \end{aligned}$$

Which simplifies to

$$y_1 = \frac{x}{x-1}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2} \, dx \\ &= \frac{x}{x-1} \int \frac{1}{\frac{x^2}{(x-1)^2}} \, dx \\ &= \frac{x}{x-1} \left(x - \frac{1}{x} - 2\ln(x) \right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\frac{x}{x-1} \right) + c_2 \left(\frac{x}{x-1} \left(x - \frac{1}{x} - 2\ln(x) \right) \right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x(x-1)^2\left(\frac{d^2}{dx^2}y(x)\right)-2y(x)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x)=\frac{2y(x)}{x(x-1)^2}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x)-\frac{2y(x)}{x(x-1)^2}=0$

☐ Check to see if x_0 is a regular singular point

  ◦ Define functions

  $\left[P_2(x)=0, P_3(x)=-\frac{2}{(x-1)^2 x}\right]$

  ◦ $x\cdot P_2(x)$ is analytic at $x=0$

  $\left.(x\cdot P_2(x))\right|_{x=0}=0$

  ◦ $x^2\cdot P_3(x)$ is analytic at $x=0$

  $\left.(x^2\cdot P_3(x))\right|_{x=0}=0$

  ◦ $x=0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=0$

- Multiply by denominators

  $x(x-1)^2\left(\frac{d^2}{dx^2}y(x)\right)-2y(x)=0$

- Assume series solution for $y(x)$

  $y(x)=\sum_{k=0}^{\infty}a_k x^{k+r}$

☐ Rewrite ODE with series expansions

  ◦ Convert $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m=1..3$

  $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)(k+r-1)x^{k+r-2+m}$

  ◦ Shift index using $k->k+2-m$

  $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=-2+m}^{\infty}a_{k+2-m}(k+2-m+r)(k+1-m+r)x^{k+r}$

  Rewrite ODE with series expansions

  $a_0r(-1+r)x^{-1+r}+(a_1(1+r)r-2a_0(r^2-r+1))x^r+\left(\sum_{k=1}^{\infty}(a_{k+1}(k+1+r)(k+r)-2a_k(k^2\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r(-1+r)=0$

- Values of r that satisfy the indicial equation

  $r\in\{0,1\}$

- Each term must be 0

  $a_1(1+r)r-2a_0(r^2-r+1)=0$

- Each term in the series must be 0, giving the recursion relation

  $(-2a_k+a_{k-1}+a_{k+1})k^2+((-4a_k+2a_{k-1}+2a_{k+1})r+2a_k-3a_{k-1}+a_{k+1})k+(-2a_k+a_{k-1}-$

- Shift index using $k->k+1$

  $(-2a_{k+1}+a_k+a_{k+2})(k+1)^2+((-4a_{k+1}+2a_k+2a_{k+2})r+2a_{k+1}-3a_k+a_{k+2})(k+1)+(-$

- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{k^2 a_k - 2k^2 a_{k+1} + 2kr a_k - 4kr a_{k+1} + r^2 a_k - 2r^2 a_{k+1} - k a_k - 2k a_{k+1} - r a_k - 2r a_{k+1} - 2a_{k+1}}{k^2 + 2kr + r^2 + 3k + 3r + 2}$
- Recursion relation for $r = 0$

  $a_{k+2} = -\frac{k^2 a_k - 2k^2 a_{k+1} - k a_k - 2k a_{k+1} - 2a_{k+1}}{k^2 + 3k + 2}$
- Solution for $r = 0$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^k, a_{k+2} = -\frac{k^2 a_k - 2k^2 a_{k+1} - k a_k - 2k a_{k+1} - 2a_{k+1}}{k^2 + 3k + 2}, -2a_0 = 0\right]$
- Recursion relation for $r = 1$

  $a_{k+2} = -\frac{k^2 a_k - 2k^2 a_{k+1} + k a_k - 6k a_{k+1} - 6a_{k+1}}{k^2 + 5k + 6}$
- Solution for $r = 1$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+1}, a_{k+2} = -\frac{k^2 a_k - 2k^2 a_{k+1} + k a_k - 6k a_{k+1} - 6a_{k+1}}{k^2 + 5k + 6}, 2a_1 - 2a_0 = 0\right]$
- Combine solutions and rename parameters

  $\left[y(x) = \left(\sum_{k=0}^{\infty} a_k x^k\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+1}\right), a_{k+2} = -\frac{k^2 a_k - 2k^2 a_{k+1} - k a_k - 2k a_{k+1} - 2a_{k+1}}{k^2 + 3k + 2}, -2a_0 = 0, b_{k+2} = -\frac{k^2 \ldots}{\ldots}\right.$

2.1.299 Problem 302

Internal problem ID [9471]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 302
Date solved : `Monday, January 27, 2025 at 06:03:11 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$y'' - 2xy' + x^2y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.154 (sec)

Writing the ode as

$$y'' - 2xy' + x^2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -2x \\ C &= x^2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.568: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-2x}{1}\, dx} \\ &= z_1 e^{\frac{x^2}{2}} \\ &= z_1 \left(e^{\frac{x^2}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = e^{\frac{x^2}{2}} \cos(x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-2x}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{x^2}}{(y_1)^2}\,dx \\
&= y_1(\tan(x))
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{\frac{x^2}{2}}\cos(x)\right) + c_2\left(\mathrm{e}^{\frac{x^2}{2}}\cos(x)(\tan(x))\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$\frac{d^2}{dx^2}y(x) - 2x\left(\frac{d}{dx}y(x)\right) + x^2 y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^k$

☐ Rewrite ODE with series expansions

  ◦ Convert $x^2 \cdot y(x)$ to series expansion

    $x^2 \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+2}$

  ◦ Shift index using $k->k-2$

    $x^2 \cdot y(x) = \sum_{k=2}^{\infty} a_{k-2} x^k$

  ◦ Convert $x \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion

    $x \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k k\, x^k$

  ◦ Convert $\frac{d^2}{dx^2}y(x)$ to series expansion

    $\frac{d^2}{dx^2}y(x) = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$

  ◦ Shift index using $k->k+2$

    $\frac{d^2}{dx^2}y(x) = \sum_{k=0}^{\infty} a_{k+2}(k+2)(k+1)\, x^k$

  Rewrite ODE with series expansions

  $2a_2 + (6a_3 - 2a_1)x + \left(\sum_{k=2}^{\infty} \left(a_{k+2}(k+2)(k+1) - 2a_k k + a_{k-2}\right) x^k\right) = 0$

- The coefficients of each power of x must be 0

  $[2a_2 = 0, 6a_3 - 2a_1 = 0]$

- Solve for the dependent coefficient(s)

  $\left\{a_2 = 0, a_3 = \frac{a_1}{3}\right\}$

- Each term in the series must be 0, giving the recursion relation

  $(k^2 + 3k + 2)\, a_{k+2} - 2a_k k + a_{k-2} = 0$

- Shift index using $k->k+2$

  $$\left((k+2)^2+3k+8\right)a_{k+4}-2a_{k+2}(k+2)+a_k=0$$

- Recursion relation that defines the series solution to the ODE

  $$\left[y(x)=\sum_{k=0}^{\infty}a_kx^k, a_{k+4}=\frac{2ka_{k+2}-a_k+4a_{k+2}}{k^2+7k+12}, a_2=0, a_3=\frac{a_1}{3}\right]$$

$$y(x)\to\frac{1}{2}e^{\frac{1}{2}x(x-2i)}\left(2c_1-ic_2e^{2ix}\right)$$

2.1.300 Problem 303

Internal problem ID [9472]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 303
Date solved : `Monday, January 27, 2025 at 06:03:11 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x\left(-x^2+2\right)y''-\left(x^2+4x+2\right)\left((1-x)\,y'+y\right)=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.509 (sec)

Writing the ode as

$$\left(-x^3+2x\right)y''+\left(x^3+3x^2-2x-2\right)y'+\left(-x^2-4x-2\right)y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= -x^3+2x \\ B &= x^3+3x^2-2x-2 \\ C &= -x^2-4x-2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{x^6+2x^5-5x^4-16x^3+24x^2+24x+12}{4\left(x^3-2x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^6+2x^5-5x^4-16x^3+24x^2+24x+12 \\ t &= 4\left(x^3-2x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{x^6+2x^5-5x^4-16x^3+24x^2+24x+12}{4\left(x^3-2x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.570: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 6 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^3 - 2x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = \sqrt{2}$ of order 2. There is a pole at $x = -\sqrt{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} + \frac{3}{2x} + \frac{3}{4x^2} + \frac{3}{4\left(x - \sqrt{2}\right)^2} + \frac{3}{4\left(x + \sqrt{2}\right)^2} + \frac{-\frac{5\sqrt{2}}{8} - \frac{1}{2}}{x - \sqrt{2}} + \frac{\frac{5\sqrt{2}}{8} - \frac{1}{2}}{x + \sqrt{2}}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{1}{2} \end{aligned}$$

For the pole at $x = \sqrt{2}$ let b be the coefficient of $\frac{1}{\left(x - \sqrt{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{1}{2} \end{aligned}$$

For the pole at $x=-\sqrt{2}$ let b be the coefficient of $\frac{1}{\left(x+\sqrt{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b=\frac{3}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0\\
\alpha_c^+ &= \frac{1}{2}+\sqrt{1+4b}=\frac{3}{2}\\
\alpha_c^- &= \frac{1}{2}-\sqrt{1+4b}=-\frac{1}{2}
\end{aligned}
$$

Since the order of r at ∞ is $O_r(\infty)=0$ then

$$
v=\frac{-O_r(\infty)}{2}=\frac{0}{2}=0
$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0\leq i\leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i\\
&= \sum_{i=0}^{0} a_i x^i
\end{aligned} \tag{8}
$$

Let a be the coefficient of $x^v=x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$
\sqrt{r}\approx \frac{1}{2}+\frac{1}{2x}-\frac{1}{2x^2}-\frac{3}{2x^3}+\frac{21}{4x^4}-\frac{43}{4x^5}+\frac{135}{4x^6}-\frac{147}{4x^7}+\dots \tag{9}
$$

Comparing Eq. (9) with Eq. (8) shows that

$$
a=\frac{1}{2}
$$

From Eq. (9) the sum up to $v=0$ gives

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i\\
&= \frac{1}{2}
\end{aligned} \tag{10}
$$

Now we need to find b, where b be the coefficient of $x^{v-1}=x^{-1}=\frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$
\left([\sqrt{r}]_\infty\right)^2=\frac{1}{4}
$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v=0$ or not. Since $v=0$ then starting from $r=\frac{s}{t}$ and doing long division in the form

$$
r=Q+\frac{R}{t}
$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$
\begin{aligned}
r &= \frac{s}{t}\\
&= \frac{x^6+2x^5-5x^4-16x^3+24x^2+24x+12}{4x^6-16x^4+16x^2}\\
&= Q+\frac{R}{4x^6-16x^4+16x^2}\\
&= \left(\frac{1}{4}\right)+\left(\frac{2x^5-x^4-16x^3+20x^2+24x+12}{4x^6-16x^4+16x^2}\right)\\
&= \frac{1}{4}+\frac{2x^5-x^4-16x^3+20x^2+24x+12}{4x^6-16x^4+16x^2}
\end{aligned}
$$

Since the degree of t is 6, then we see that the coefficient of the term x^5 in the remainder R is 2. Dividing this by leading coefficient in t which is 4 gives $\frac{1}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(\frac{1}{2}\right) - (0) \\ &= \frac{1}{2} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{\frac{1}{2}}{\frac{1}{2}} - 0\right) &= \frac{1}{2} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{\frac{1}{2}}{\frac{1}{2}} - 0\right) &= -\frac{1}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^6 + 2x^5 - 5x^4 - 16x^3 + 24x^2 + 24x + 12}{4\left(x^3 - 2x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{3}{2}$	$-\frac{1}{2}$
$\sqrt{2}$	2	0	$\frac{3}{2}$	$-\frac{1}{2}$
$-\sqrt{2}$	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	$\frac{1}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^+ - \left(\alpha_{c_1}^+ + \alpha_{c_2}^- + \alpha_{c_3}^-\right) \\ &= \frac{1}{2} - \left(\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c}\right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x - c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x - c_2}\right) + \left((-)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^-}{x - c_3}\right) + (+)[\sqrt{r}]_\infty \\ &= \frac{3}{2x} - \frac{1}{2\left(x - \sqrt{2}\right)} - \frac{1}{2\left(x + \sqrt{2}\right)} + \left(\frac{1}{2}\right) \\ &= \frac{3}{2x} - \frac{1}{2\left(x - \sqrt{2}\right)} - \frac{1}{2\left(x + \sqrt{2}\right)} + \frac{1}{2} \\ &= \frac{x^3 + x^2 - 2x - 6}{2x^3 - 4x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{3}{2x} - \frac{1}{2\left(x-\sqrt{2}\right)} - \frac{1}{2\left(x+\sqrt{2}\right)} + \frac{1}{2}\right)(0) + \left(\left(-\frac{3}{2x^2} + \frac{1}{2\left(x-\sqrt{2}\right)^2} + \frac{1}{2\left(x+\sqrt{2}\right)^2}\right) + \left(\frac{3}{2x}\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx} \\
&= \mathrm{e}^{\int \left(\frac{3}{2x} - \frac{1}{2\left(x-\sqrt{2}\right)} - \frac{1}{2\left(x+\sqrt{2}\right)} + \frac{1}{2}\right) dx} \\
&= \frac{x^{3/2} \mathrm{e}^{\frac{x}{2}}}{\sqrt{x-\sqrt{2}}\, \sqrt{x+\sqrt{2}}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{x^3+3x^2-2x-2}{-x^3+2x}\, dx} \\
&= z_1 e^{\frac{x}{2} + \frac{\ln(x)}{2} + \frac{\ln\left(x^2-2\right)}{2}} \\
&= z_1 \left(\sqrt{x}\, \sqrt{x^2-2}\, \mathrm{e}^{\frac{x}{2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = x^2 \mathrm{e}^x$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x^3+3x^2-2x-2}{-x^3+2x}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{x+\ln(x)+\ln\left(x^2-2\right)}}{(y_1)^2}\, dx \\
&= y_1 \left(-\frac{(x-1)\, \mathrm{e}^{x+\ln(x)+\ln\left(x^2-2\right)} \mathrm{e}^{-2x}}{x^3\left(x^2-2\right)}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(x^2 \mathrm{e}^x\right) + c_2\left(x^2 \mathrm{e}^x \left(-\frac{(x-1)\, \mathrm{e}^{x+\ln(x)+\ln\left(x^2-2\right)} \mathrm{e}^{-2x}}{x^3\left(x^2-2\right)}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x(-x^2+2)\left(\frac{d^2}{dx^2}y(x)\right)-(x^2+4x+2)\left((1-x)\left(\frac{d}{dx}y(x)\right)+y(x)\right)=0$

- Highest derivative means the order of the ODE is 2

$\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

$\frac{d^2}{dx^2}y(x)=-\frac{(x^2+4x+2)y(x)}{x(x^2-2)}+\frac{(x^2+4x+2)(x-1)\left(\frac{d}{dx}y(x)\right)}{x(x^2-2)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

$\frac{d^2}{dx^2}y(x)-\frac{(x^2+4x+2)(x-1)\left(\frac{d}{dx}y(x)\right)}{x(x^2-2)}+\frac{(x^2+4x+2)y(x)}{x(x^2-2)}=0$

- □ Check to see if x_0 is a regular singular point
  - ○ Define functions

    $\left[P_2(x)=-\frac{(x-1)(x^2+4x+2)}{x(x^2-2)}, P_3(x)=\frac{x^2+4x+2}{x(x^2-2)}\right]$
  - ○ $x\cdot P_2(x)$ is analytic at $x=0$

    $(x\cdot P_2(x))\bigg|_{x=0}=-1$
  - ○ $x^2\cdot P_3(x)$ is analytic at $x=0$

    $(x^2\cdot P_3(x))\bigg|_{x=0}=0$
  - ○ $x=0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=0$
- Multiply by denominators

$x(x^2-2)\left(\frac{d^2}{dx^2}y(x)\right)-(x-1)(x^2+4x+2)\left(\frac{d}{dx}y(x)\right)+(x^2+4x+2)y(x)=0$

- Assume series solution for $y(x)$

$y(x)=\sum_{k=0}^{\infty}a_k x^{k+r}$

- □ Rewrite ODE with series expansions
  - ○ Convert $x^m\cdot y(x)$ to series expansion for $m=0..2$

    $x^m\cdot y(x)=\sum_{k=0}^{\infty}a_k x^{k+r+m}$
  - ○ Shift index using $k->k-m$

    $x^m\cdot y(x)=\sum_{k=m}^{\infty}a_{k-m}x^{k+r}$
  - ○ Convert $x^m\cdot\left(\frac{d}{dx}y(x)\right)$ to series expansion for $m=0..3$

    $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,x^{k+r-1+m}$
  - ○ Shift index using $k->k+1-m$

    $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,x^{k+r}$
  - ○ Convert $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m=1..3$

    $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)(k+r-1)\,x^{k+r-2+m}$
  - ○ Shift index using $k->k+2-m$

    $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=-2+m}^{\infty}a_{k+2-m}(k+2-m+r)(k+1-m+r)\,x^{k+r}$

  Rewrite ODE with series expansions

$$-2a_0r(-2+r)\,x^{-1+r}+(-2a_1(1+r)\,(-1+r)+2a_0(1+r))\,x^r+\big(-2a_2(2+r)\,r+2a_1(2+r)+$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $$-2r(-2+r)=0$$
- Values of r that satisfy the indicial equation
  $$r\in\{0,2\}$$
- The coefficients of each power of x must be 0
  $$\big[-2a_1(1+r)\,(-1+r)+2a_0(1+r)=0,-2a_2(2+r)\,r+2a_1(2+r)+a_0(-2+r)^2=0\big]$$
- Solve for the dependent coefficient(s)
  $$\left\{a_1=\frac{a_0}{-1+r},a_2=\frac{a_0(r^2-5r+10)}{2(r^2+r-2)}\right\}$$
- Each term in the series must be 0, giving the recursion relation
  $$a_{k-1}(k-3+r)^2-2a_{k+1}(k+r+1)\,(k+r-1)+(2a_k-a_{k-2})\,k+(2a_k-a_{k-2})\,r+2a_k+3a_{k-}$$
- Shift index using $k->k+2$
  $$a_{k+1}(k+r-1)^2-2a_{k+3}(k+3+r)\,(k+r+1)+(2a_{k+2}-a_k)\,(k+2)+(2a_{k+2}-a_k)\,r+2a_{k+2}$$
- Recursion relation that defines series solution to ODE
  $$a_{k+3}=\frac{k^2a_{k+1}+2kra_{k+1}+r^2a_{k+1}-a_kk-2ka_{k+1}+2ka_{k+2}-a_kr-2ra_{k+1}+2ra_{k+2}+a_k+a_{k+1}+6a_{k+2}}{2(k+3+r)(k+r+1)}$$
- Recursion relation for $r=0$
  $$a_{k+3}=\frac{k^2a_{k+1}-a_kk-2ka_{k+1}+2ka_{k+2}+a_k+a_{k+1}+6a_{k+2}}{2(k+3)(k+1)}$$
- Solution for $r=0$
  $$\left[y(x)=\sum_{k=0}^{\infty}a_kx^k,a_{k+3}=\frac{k^2a_{k+1}-a_kk-2ka_{k+1}+2ka_{k+2}+a_k+a_{k+1}+6a_{k+2}}{2(k+3)(k+1)},a_1=-a_0,a_2=-\frac{5a_0}{2}\right]$$
- Recursion relation for $r=2$
  $$a_{k+3}=\frac{k^2a_{k+1}-a_kk+2ka_{k+1}+2ka_{k+2}-a_k+a_{k+1}+10a_{k+2}}{2(k+5)(k+3)}$$
- Solution for $r=2$
  $$\left[y(x)=\sum_{k=0}^{\infty}a_kx^{k+2},a_{k+3}=\frac{k^2a_{k+1}-a_kk+2ka_{k+1}+2ka_{k+2}-a_k+a_{k+1}+10a_{k+2}}{2(k+5)(k+3)},a_1=a_0,a_2=\frac{a_0}{2}\right]$$
- Combine solutions and rename parameters
  $$\left[y(x)=\left(\sum_{k=0}^{\infty}a_kx^k\right)+\left(\sum_{k=0}^{\infty}b_kx^{k+2}\right),a_{k+3}=\frac{k^2a_{k+1}-ka_k-2ka_{k+1}+2ka_{k+2}+a_k+a_{k+1}+6a_{k+2}}{2(k+3)(k+1)},a_1=-a_0,a\right.$$

2.1.301 Problem 304

Internal problem ID [9473]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 304
Date solved : `Monday, January 27, 2025 at 06:03:12 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2(1+x)\,y''-(1+2x)\,(xy'-y)=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.202 (sec)

Writing the ode as

$$x^2(1+x)\,y''+\left(-2x^2-x\right)y'+(1+2x)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A&=x^2(1+x)\\ B&=-2x^2-x\\ C&=1+2x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r&=\frac{s}{t} \\ &=\frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{-4x-1}{4\left(x^2+x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s&=-4x-1\\ t&=4\left(x^2+x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{-4x-1}{4\left(x^2+x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.572: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 1 \\ &= 3 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^2 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 3 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 3 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{2 + 2x} - \frac{1}{2x} + \frac{3}{4\,(1 + x)^2} - \frac{1}{4x^2}$$

For the pole at $x = -1$ let b be the coefficient of $\frac{1}{(1+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{1}{2} \end{aligned}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $3 > 2$ then

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= 0 \\
\alpha_\infty^- &= 1
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{-4x-1}{4\left(x^2+x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
-1	2	0	$\frac{3}{2}$	$-\frac{1}{2}$
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
3	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = 0$ then

$$\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^- + \alpha_{c_2}^+\right) \\
&= 0 - (0) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x-c_2} \right) + (+)[\sqrt{r}]_\infty \\
&= -\frac{1}{2\left(1+x\right)} + \frac{1}{2x} + (0) \\
&= -\frac{1}{2\left(1+x\right)} + \frac{1}{2x} \\
&= \frac{1}{2x\left(1+x\right)}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$
\begin{aligned}
(0)+2\left(-\frac{1}{2(1+x)}+\frac{1}{2x}\right)(0)+\left(\left(\frac{1}{2(1+x)^2}-\frac{1}{2x^2}\right)+\left(-\frac{1}{2(1+x)}+\frac{1}{2x}\right)^2-\left(\frac{-4x-1}{4(x^2+x)^2}\right)\right)&=0\\
0&=0
\end{aligned}
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z''=rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx}\\
&= \mathrm{e}^{\int \left(-\frac{1}{2(1+x)}+\frac{1}{2x}\right)dx}\\
&= \frac{\sqrt{x}}{\sqrt{1+x}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx}\\
&= z_1 e^{-\int \frac{1}{2}\frac{-2x^2-x}{x^2(1+x)}\, dx}\\
&= z_1 e^{\frac{\ln(x(1+x))}{2}}\\
&= z_1\left(\sqrt{x(1+x)}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{\sqrt{x(1+x)}\,\sqrt{x}}{\sqrt{1+x}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-2x^2-x}{x^2(1+x)}\, dx}}{(y_1)^2}\, dx\\
&= y_1 \int \frac{e^{\ln(x(1+x))}}{(y_1)^2}\, dx\\
&= y_1(x+\ln(x))
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2\\
&= c_1\left(\frac{\sqrt{x(1+x)}\,\sqrt{x}}{\sqrt{1+x}}\right)+c_2\left(\frac{\sqrt{x(1+x)}\,\sqrt{x}}{\sqrt{1+x}}(x+\ln(x))\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2(x+1)\left(\frac{d^2}{dx^2}y(x)\right)-(2x+1)\left(x\left(\frac{d}{dx}y(x)\right)-y(x)\right)=0$

- Highest derivative means the order of the ODE is 2

$\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

$\frac{d^2}{dx^2}y(x)=-\frac{(2x+1)y(x)}{x^2(x+1)}+\frac{(2x+1)\left(\frac{d}{dx}y(x)\right)}{x(x+1)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

$\frac{d^2}{dx^2}y(x)-\frac{(2x+1)\left(\frac{d}{dx}y(x)\right)}{x(x+1)}+\frac{(2x+1)y(x)}{x^2(x+1)}=0$

□ Check to see if x_0 is a regular singular point

- ◦ Define functions

$\left[P_2(x)=-\frac{2x+1}{x(x+1)},P_3(x)=\frac{2x+1}{x^2(x+1)}\right]$

- ◦ $(x+1)\cdot P_2(x)$ is analytic at $x=-1$

$\left((x+1)\cdot P_2(x)\right)\Big|_{x=-1}=-1$

- ◦ $(x+1)^2\cdot P_3(x)$ is analytic at $x=-1$

$\left((x+1)^2\cdot P_3(x)\right)\Big|_{x=-1}=0$

- ◦ $x=-1$is a regular singular point

Check to see if x_0 is a regular singular point

$x_0=-1$

- Multiply by denominators

$x^2(x+1)\left(\frac{d^2}{dx^2}y(x)\right)-x(2x+1)\left(\frac{d}{dx}y(x)\right)+(2x+1)y(x)=0$

- Change variables using $x=u-1$ so that the regular singular point is at $u=0$

$(u^3-2u^2+u)\left(\frac{d^2}{du^2}y(u)\right)+(-2u^2+3u-1)\left(\frac{d}{du}y(u)\right)+(2u-1)y(u)=0$

- Assume series solution for $y(u)$

$y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

□ Rewrite ODE with series expansions

- ◦ Convert $u^m\cdot y(u)$ to series expansion for $m=0..1$

$u^m\cdot y(u)=\sum_{k=0}^{\infty}a_k u^{k+r+m}$

- ◦ Shift index using $k->k-m$

$u^m\cdot y(u)=\sum_{k=m}^{\infty}a_{k-m}u^{k+r}$

- ◦ Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..2$

$u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,u^{k+r-1+m}$

- ◦ Shift index using $k->k+1-m$

$u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,u^{k+r}$

- ◦ Convert $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m=1..3$

$u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)(k+r-1)\,u^{k+r-2+m}$

- ◦ Shift index using $k->k+2-m$

$$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\,u^{k+r}$$

Rewrite ODE with series expansions

$$a_0 r(-2+r)\,u^{-1+r} + \left(a_1(1+r)(-1+r) - a_0(2r^2-5r+1)\right)u^r + \left(\sum_{k=1}^{\infty} \left(a_{k+1}(k+1+r)(k+r-1\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $r(-2+r) = 0$
- Values of r that satisfy the indicial equation
  $r \in \{0, 2\}$
- Each term must be 0
  $a_1(1+r)(-1+r) - a_0(2r^2-5r+1) = 0$
- Each term in the series must be 0, giving the recursion relation
  $(-2a_k + a_{k-1} + a_{k+1})\,k^2 + ((-4a_k + 2a_{k-1} + 2a_{k+1})\,r + 5a_k - 5a_{k-1})\,k + (-2a_k + a_{k-1} + a_{k+1})\,r^2$
- Shift index using $k- >k+1$
  $(-2a_{k+1} + a_k + a_{k+2})\,(k+1)^2 + ((-4a_{k+1} + 2a_k + 2a_{k+2})\,r + 5a_{k+1} - 5a_k)\,(k+1) + (-2a_{k+1} + a_k$
- Recursion relation that defines series solution to ODE
  $a_{k+2} = -\frac{k^2a_k - 2k^2a_{k+1} + 2kra_k - 4kra_{k+1} + r^2a_k - 2r^2a_{k+1} - 3ka_k + ka_{k+1} - 3ra_k + ra_{k+1} + 2a_k + 2a_{k+1}}{k^2+2kr+r^2+2k+2r}$
- Recursion relation for $r = 0$
  $a_{k+2} = -\frac{k^2a_k - 2k^2a_{k+1} - 3ka_k + ka_{k+1} + 2a_k + 2a_{k+1}}{k^2+2k}$
- Series not valid for $r = 0$, division by 0 in the recursion relation at $k = 0$
  $a_{k+2} = -\frac{k^2a_k - 2k^2a_{k+1} - 3ka_k + ka_{k+1} + 2a_k + 2a_{k+1}}{k^2+2k}$
- Recursion relation for $r = 2$
  $a_{k+2} = -\frac{k^2a_k - 2k^2a_{k+1} + ka_k - 7ka_{k+1} - 4a_{k+1}}{k^2+6k+8}$
- Solution for $r = 2$
  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+2}, a_{k+2} = -\frac{k^2a_k - 2k^2a_{k+1} + ka_k - 7ka_{k+1} - 4a_{k+1}}{k^2+6k+8}, 3a_1 + a_0 = 0\right]$
- Revert the change of variables $u = x+1$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k (x+1)^{k+2}, a_{k+2} = -\frac{k^2a_k - 2k^2a_{k+1} + ka_k - 7ka_{k+1} - 4a_{k+1}}{k^2+6k+8}, 3a_1 + a_0 = 0\right]$

2.1.302 Problem 305

Internal problem ID [9474]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 305
Date solved : `Monday, January 27, 2025 at 06:03:13 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$2(2-x)\,x^2y''-(4-x)\,xy'+(3-x)\,y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.161 (sec)

Writing the ode as

$$\left(-2x^3+4x^2\right)y''+\left(x^2-4x\right)y'+(3-x)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=-2x^3+4x^2\\B&=x^2-4x\\C&=3-x\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned}r&=\frac{s}{t}\\&=\frac{2AB'-2BA'+B^2-4AC}{4A^2}\end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{-3}{16\left(-2+x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned}s&=-3\\t&=16(-2+x)^2\end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(-\frac{3}{16\left(-2+x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.574: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16(-2+x)^2$. There is a pole at $x = 2$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{3}{16\,(-2+x)^2}$$

For the pole at $x = 2$ let b be the coefficient of $\frac{1}{(-2+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{4} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = -\frac{3}{16\,(-2+x)^2}$$

Since the gcd$(s,t)=1$. This gives $b=-\frac{3}{16}$. Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= 0\\ \alpha_\infty^+ &= \frac{1}{2}+\sqrt{1+4b}=\frac{3}{4}\\ \alpha_\infty^- &= \frac{1}{2}-\sqrt{1+4b}=\frac{1}{4}\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r=-\frac{3}{16\,(-2+x)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
2	2	0	$\frac{3}{4}$	$\frac{1}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{3}{4}$	$\frac{1}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^-=\frac{1}{4}$ then

$$\begin{aligned}d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right)\\ &= \frac{1}{4}-\left(\frac{1}{4}\right)\\ &= 0\end{aligned}$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$\omega=\sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c+\frac{\alpha_c^{s(c)}}{x-c}\right)+s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}\omega &= \left((-)[\sqrt{r}]_{c_1}+\frac{\alpha_{c_1}^-}{x-c_1}\right)+(-)[\sqrt{r}]_\infty\\ &= \frac{1}{-8+4x}+(-)\,(0)\\ &= \frac{1}{-8+4x}\\ &= \frac{1}{-8+4x}\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p''+2\omega p'+\left(\omega'+\omega^2-r\right)p=0 \tag{1A}$$

Let

$$p(x)=1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(\frac{1}{-8+4x}\right)(0)+\left(\left(-\frac{1}{4\left(-2+x\right)^{2}}\right)+\left(\frac{1}{-8+4x}\right)^{2}-\left(-\frac{3}{16\left(-2+x\right)^{2}}\right)\right)=0$$
$$0=0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z''=rz$ is

$$\begin{aligned}z_1(x)&=pe^{\int \omega\, dx}\\&=\mathrm{e}^{\int \frac{1}{-8+4x}dx}\\&=\left(-2+x\right)^{1/4}\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}y_1&=z_1e^{\int -\frac{1}{2}\frac{B}{A}\, dx}\\&=z_1e^{-\int \frac{1}{2}\frac{x^2-4x}{-2x^3+4x^2}\, dx}\\&=z_1e^{\frac{\ln(x)}{2}-\frac{\ln(-2+x)}{4}}\\&=z_1\left(\frac{\sqrt{x}}{\left(-2+x\right)^{1/4}}\right)\end{aligned}$$

Which simplifies to

$$y_1=\sqrt{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2=y_1\int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}y_2&=y_1\int \frac{\mathrm{e}^{\int -\frac{x^2-4x}{-2x^3+4x^2}\, dx}}{\left(y_1\right)^2}\, dx\\&=y_1\int \frac{\mathrm{e}^{\ln(x)-\frac{\ln(-2+x)}{2}}}{\left(y_1\right)^2}\, dx\\&=y_1\left(\frac{2\,\mathrm{e}^{\ln(x)-\frac{\ln(-2+x)}{2}}\left(-2+x\right)}{x}\right)\end{aligned}$$

Therefore the solution is

$$\begin{aligned}y&=c_1y_1+c_2y_2\\&=c_1\left(\sqrt{x}\right)+c_2\left(\sqrt{x}\left(\frac{2\,\mathrm{e}^{\ln(x)-\frac{\ln(-2+x)}{2}}\left(-2+x\right)}{x}\right)\right)\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve
$2(-x+2)\,x^2\left(\frac{d^2}{dx^2}y(x)\right)-x(4-x)\left(\frac{d}{dx}y(x)\right)+(-x+3)\,y(x)=0$

- Highest derivative means the order of the ODE is 2
$\frac{d^2}{dx^2}y(x)$
- Isolate 2nd derivative
$\frac{d^2}{dx^2}y(x)=-\frac{(x-3)y(x)}{2x^2(x-2)}+\frac{(-4+x)\left(\frac{d}{dx}y(x)\right)}{2x(x-2)}$
- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea
$\frac{d^2}{dx^2}y(x)-\frac{(-4+x)\left(\frac{d}{dx}y(x)\right)}{2x(x-2)}+\frac{(x-3)y(x)}{2x^2(x-2)}=0$

☐ Check to see if x_0 is a regular singular point
  - Define functions
  $\left[P_2(x)=-\frac{-4+x}{2x(x-2)},P_3(x)=\frac{x-3}{2x^2(x-2)}\right]$
  - $x\cdot P_2(x)$ is analytic at $x=0$
  $\left.(x\cdot P_2(x))\right|_{x=0}=-1$
  - $x^2\cdot P_3(x)$ is analytic at $x=0$
  $\left.(x^2\cdot P_3(x))\right|_{x=0}=\frac{3}{4}$
  - $x=0$is a regular singular point

  Check to see if x_0 is a regular singular point
  $x_0=0$
- Multiply by denominators
$2x^2(x-2)\left(\frac{d^2}{dx^2}y(x)\right)-x(-4+x)\left(\frac{d}{dx}y(x)\right)+(x-3)\,y(x)=0$
- Assume series solution for $y(x)$
$y(x)=\sum_{k=0}^{\infty}a_kx^{k+r}$

☐ Rewrite ODE with series expansions
  - Convert $x^m\cdot y(x)$ to series expansion for $m=0..1$
  $x^m\cdot y(x)=\sum_{k=0}^{\infty}a_kx^{k+r+m}$
  - Shift index using $k->k-m$
  $x^m\cdot y(x)=\sum_{k=m}^{\infty}a_{k-m}x^{k+r}$
  - Convert $x^m\cdot\left(\frac{d}{dx}y(x)\right)$ to series expansion for $m=1..2$
  $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,x^{k+r-1+m}$
  - Shift index using $k->k+1-m$
  $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,x^{k+r}$
  - Convert $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m=2..3$
  $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,x^{k+r-2+m}$
  - Shift index using $k->k+2-m$
  $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=-2+m}^{\infty}a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$

  Rewrite ODE with series expansions

$$-a_0(-1+2r)(-3+2r)x^r + \left(\sum_{k=1}^{\infty} \left(-a_k(2k+2r-1)(2k+2r-3) + a_{k-1}(2k+2r-3)(k-2\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $-(-1+2r)(-3+2r) = 0$
- Values of r that satisfy the indicial equation
  $r \in \left\{\frac{1}{2}, \frac{3}{2}\right\}$
- Each term in the series must be 0, giving the recursion relation
  $-4\left(\left(-\frac{k}{2}-\frac{r}{2}+1\right)a_{k-1} + \left(k+r-\frac{1}{2}\right)a_k\right)\left(k+r-\frac{3}{2}\right) = 0$
- Shift index using $k->k+1$
  $-4\left(\left(-\frac{k}{2}+\frac{1}{2}-\frac{r}{2}\right)a_k + \left(k+\frac{1}{2}+r\right)a_{k+1}\right)\left(k+r-\frac{1}{2}\right) = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+1} = \frac{(k+r-1)a_k}{2k+1+2r}$
- Recursion relation for $r = \frac{1}{2}$
  $a_{k+1} = \frac{\left(k-\frac{1}{2}\right)a_k}{2k+2}$
- Solution for $r = \frac{1}{2}$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}, a_{k+1} = \frac{\left(k-\frac{1}{2}\right)a_k}{2k+2}\right]$
- Recursion relation for $r = \frac{3}{2}$
  $a_{k+1} = \frac{\left(k+\frac{1}{2}\right)a_k}{2k+4}$
- Solution for $r = \frac{3}{2}$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+\frac{3}{2}}, a_{k+1} = \frac{\left(k+\frac{1}{2}\right)a_k}{2k+4}\right]$
- Combine solutions and rename parameters
  $\left[y(x) = \left(\sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{3}{2}}\right), a_{k+1} = \frac{\left(k-\frac{1}{2}\right)a_k}{2k+2}, b_{k+1} = \frac{\left(k+\frac{1}{2}\right)b_k}{2k+4}\right]$

2.1.303 Problem 306

Internal problem ID [9475]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 306
Date solved : `Monday, January 27, 2025 at 06:03:14 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$(1-x)\,x^2y''+(5x-4)\,xy'+(6-9x)\,y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.187 (sec)

Writing the ode as

$$\left(-x^3+x^2\right)y''+\left(5x^2-4x\right)y'+(6-9x)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=-x^3+x^2\\ B&=5x^2-4x\\ C&=6-9x\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned}r&=\frac{s}{t}\\ &=\frac{2AB'-2BA'+B^2-4AC}{4A^2}\end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{-x+4}{4x\left(-1+x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned}s&=-x+4\\ t&=4x(-1+x)^2\end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{-x+4}{4x\left(-1+x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.576: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 3 - 1 \\
&= 2
\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x(-1+x)^2$. There is a pole at $x = 0$ of order 1. There is a pole at $x = 1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 1. For the pole at $x = 0$ of order 1 then

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= 1 \\
\alpha_c^- &= 1
\end{aligned}$$

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{-1+x} + \frac{1}{x} + \frac{3}{4\,(-1+x)^2}$$

For the pole at $x = 1$ let b be the coefficient of $\frac{1}{(-1+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{-x+4}{4x\left(-1+x\right)^2}$$

Since the gcd$(s,t) = 1$. This gives $b = -\frac{1}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{-x+4}{4x\left(-1+x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	1	0	0	1
1	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^-\right) \\
&= \frac{1}{2} - \left(\frac{1}{2}\right) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2}\right) + (-)[\sqrt{r}]_\infty \\
&= \frac{1}{x} - \frac{1}{2\left(-1+x\right)} + (-)\left(0\right) \\
&= \frac{1}{x} - \frac{1}{2\left(-1+x\right)} \\
&= \frac{-2+x}{2\left(-1+x\right)x}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{x} - \frac{1}{2(-1+x)}\right)(0) + \left(\left(-\frac{1}{x^2} + \frac{1}{2(-1+x)^2}\right) + \left(\frac{1}{x} - \frac{1}{2(-1+x)}\right)^2 - \left(\frac{-x+4}{4x(-1+x)^2}\right)\right) = 0$$
$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(\frac{1}{x} - \frac{1}{2(-1+x)}\right) dx} \\
&= \frac{x}{\sqrt{-1+x}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{5x^2-4x}{-x^3+x^2} \, dx} \\
&= z_1 e^{2\ln(x) + \frac{\ln(-1+x)}{2}} \\
&= z_1 \left(x^2 \sqrt{-1+x}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = x^3$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{5x^2-4x}{-x^3+x^2} \, dx}}{(y_1)^2} \, dx \\
&= y_1 \int \frac{e^{4\ln(x) + \ln(-1+x)}}{(y_1)^2} \, dx \\
&= y_1 \left(\ln(x) + \frac{1}{x}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(x^3\right) + c_2 \left(x^3 \left(\ln(x) + \frac{1}{x}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Solve

$$xy'' + (4x^2 + 1)\,y' + 4x(x^2 + 1)\,y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.161 (sec)

Writing the ode as

$$xy'' + (4x^2 + 1)\,y' + (4x^3 + 4x)\,y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x \\ B &= 4x^2 + 1 \\ C &= 4x^3 + 4x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{1}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.577: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = -\frac{1}{4x^2}$$

Since the gcd$(s,t)=1$. This gives $b=-\frac{1}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2}+\sqrt{1+4b}=\frac{1}{2} \\
\alpha_\infty^- &= \frac{1}{2}-\sqrt{1+4b}=\frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r=-\frac{1}{4x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^-=\frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\
&= \frac{1}{2}-\left(\frac{1}{2}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$
\omega=\sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c+\frac{\alpha_c^{s(c)}}{x-c}\right)+s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1}+\frac{\alpha_{c_1}^-}{x-c_1}\right)+(-)[\sqrt{r}]_\infty \\
&= \frac{1}{2x}+(-)(0) \\
&= \frac{1}{2x} \\
&= \frac{1}{2x}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p''+2\omega p'+\left(\omega'+\omega^2-r\right)p=0 \tag{1A}
$$

Let

$$
p(x)=1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{2x}\right)(0) + \left(\left(-\frac{1}{2x^2}\right) + \left(\frac{1}{2x}\right)^2 - \left(-\frac{1}{4x^2}\right)\right) = 0$$
$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= pe^{\int \omega\, dx} \\ &= e^{\int \frac{1}{2x} dx} \\ &= \sqrt{x} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{4x^2+1}{x}\, dx} \\ &= z_1 e^{-x^2 - \frac{\ln(x)}{2}} \\ &= z_1\left(\frac{e^{-x^2}}{\sqrt{x}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = e^{-x^2}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{4x^2+1}{x}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-2x^2-\ln(x)}}{(y_1)^2}\, dx \\ &= y_1(\ln(x)) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(e^{-x^2}\right) + c_2\left(e^{-x^2}(\ln(x))\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$\left(\frac{d^2}{dx^2}y(x)\right)x+(4x^2+1)\left(\frac{d}{dx}y(x)\right)+4x(x^2+1)\,y(x)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x)=(-4x^2-4)\,y(x)-\frac{(4x^2+1)\left(\frac{d}{dx}y(x)\right)}{x}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x)+\frac{(4x^2+1)\left(\frac{d}{dx}y(x)\right)}{x}+(4x^2+4)\,y(x)=0$

- □ Check to see if $x_0=0$ is a regular singular point
  - Define functions

    $\left[P_2(x)=\frac{4x^2+1}{x}, P_3(x)=4x^2+4\right]$

  - $x\cdot P_2(x)$ is analytic at $x=0$

    $\left.(x\cdot P_2(x))\right|_{x=0}=1$

  - $x^2\cdot P_3(x)$ is analytic at $x=0$

    $\left.(x^2\cdot P_3(x))\right|_{x=0}=0$

  - $x=0$is a regular singular point

  Check to see if $x_0=0$ is a regular singular point

  $x_0=0$

- Multiply by denominators

  $\left(\frac{d^2}{dx^2}y(x)\right)x+(4x^2+1)\left(\frac{d}{dx}y(x)\right)+4x(x^2+1)\,y(x)=0$

- Assume series solution for $y(x)$

  $y(x)=\sum_{k=0}^{\infty}a_k x^{k+r}$

- □ Rewrite ODE with series expansions
  - Convert $x^m\cdot y(x)$ to series expansion for $m=1..3$

    $x^m\cdot y(x)=\sum_{k=0}^{\infty}a_k x^{k+r+m}$

  - Shift index using $k->k-m$

    $x^m\cdot y(x)=\sum_{k=m}^{\infty}a_{k-m}x^{k+r}$

  - Convert $x^m\cdot\left(\frac{d}{dx}y(x)\right)$ to series expansion for $m=0..2$

    $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,x^{k+r-1+m}$

  - Shift index using $k->k+1-m$

    $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,x^{k+r}$

  - Convert $x\cdot\left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

    $x\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,x^{k+r-1}$

  - Shift index using $k->k+1$

    $x\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=-1}^{\infty}a_{k+1}(k+1+r)\,(k+r)\,x^{k+r}$

  Rewrite ODE with series expansions

$$a_0 r^2 x^{-1+r} + a_1(1+r)^2 x^r + \left(a_2(2+r)^2 + 4a_0(1+r)\right) x^{1+r} + \left(a_3(3+r)^2 + 4a_1(2+r)\right) x^{2+r} + \Big($$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $r^2 = 0$
- Values of r that satisfy the indicial equation
  $r = 0$
- The coefficients of each power of x must be 0
  $\left[a_1(1+r)^2 = 0, a_2(2+r)^2 + 4a_0(1+r) = 0, a_3(3+r)^2 + 4a_1(2+r) = 0\right]$
- Solve for the dependent coefficient(s)
  $\left\{a_1 = 0, a_2 = -\frac{4a_0(1+r)}{r^2+4r+4}, a_3 = 0\right\}$
- Each term in the series must be 0, giving the recursion relation
  $a_{k+1}(k+1)^2 + 4a_{k-1}k + 4a_{k-3} = 0$
- Shift index using $k- > k+3$
  $a_{k+4}(k+4)^2 + 4a_{k+2}(k+3) + 4a_k = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+4} = -\frac{4(ka_{k+2}+a_k+3a_{k+2})}{(k+4)^2}$
- Recursion relation for $r = 0$
  $a_{k+4} = -\frac{4(ka_{k+2}+a_k+3a_{k+2})}{(k+4)^2}$
- Solution for $r = 0$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^k, a_{k+4} = -\frac{4(ka_{k+2}+a_k+3a_{k+2})}{(k+4)^2}, a_1 = 0, a_2 = -a_0, a_3 = 0\right]$

2.1.305 Problem 309

Internal problem ID [9477]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 309
Date solved : `Monday, January 27, 2025 at 06:03:15 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$y'' - 2xy' + 8y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.227 (sec)

Writing the ode as

$$y'' - 2xy' + 8y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -2x \\ C &= 8 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 - 9}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2 - 9 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = (x^2 - 9)\, z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1, 2\}$,$\{1, 3\}$,$\{2\}$,$\{3\}$,$\{3, 4\}$,$\{1, 2, 5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.579: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 2 \\ &= -2 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx x - \frac{9}{2x} - \frac{81}{8x^3} - \frac{729}{16x^5} - \frac{32805}{128x^7} - \frac{413343}{256x^9} - \frac{11160261}{1024x^{11}} - \frac{157837977}{2048x^{13}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = 1$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= x \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = x^2$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 - 9}{1} \\ &= Q + \frac{R}{1} \\ &= (x^2 - 9) + (0) \\ &= x^2 - 9 \end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is -9. Now b can be found.

$$\begin{aligned} b &= (-9) - (0) \\ &= -9 \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= x \\ \alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-9}{1} - 1\right) &&= -5 \\ \alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-9}{1} - 1\right) &&= 4 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = x^2 - 9$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
-2	x	-5	4

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = 4$, and since there are no poles then

$$\begin{aligned} d &= \alpha_\infty^{-} \\ &= 4 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}\omega &= (-)[\sqrt{r}]_\infty \\ &= 0 + (-)(x) \\ &= -x \\ &= -x\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 4$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = x^4 + a_3x^3 + a_2x^2 + a_1x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned}(12x^2 + 6xa_3 + 2a_2) + 2(-x)\left(4x^3 + 3x^2a_3 + 2xa_2 + a_1\right) + \left((-1) + (-x)^2 - (x^2 - 9)\right) &= 0 \\ 2a_3x^3 + 4(3 + a_2)\, x^2 + 6(a_1 + a_3)\, x + 8a_0 + 2a_2 &= 0\end{aligned}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\left\{a_0 = \frac{3}{4}, a_1 = 0, a_2 = -3, a_3 = 0\right\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^4 - 3x^2 + \frac{3}{4}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}z_1(x) &= pe^{\int \omega\, dx} \\ &= \left(x^4 - 3x^2 + \frac{3}{4}\right) \mathrm{e}^{\int -x dx} \\ &= \left(x^4 - 3x^2 + \frac{3}{4}\right) \mathrm{e}^{-\frac{x^2}{2}} \\ &= \frac{(4x^4 - 12x^2 + 3)\, \mathrm{e}^{-\frac{x^2}{2}}}{4}\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-2x}{1}\, dx} \\ &= z_1 e^{\frac{x^2}{2}} \\ &= z_1 \left(\mathrm{e}^{\frac{x^2}{2}}\right)\end{aligned}$$

Which simplifies to

$$y_1 = x^4 - 3x^2 + \frac{3}{4}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-2x}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{x^2}}{(y_1)^2}\,dx \\ &= y_1 \left(\int \frac{e^{x^2}}{\left(x^4 - 3x^2 + \frac{3}{4}\right)^2} dx\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(x^4 - 3x^2 + \frac{3}{4}\right) + c_2 \left(x^4 - 3x^2 + \frac{3}{4}\left(\int \frac{e^{x^2}}{\left(x^4 - 3x^2 + \frac{3}{4}\right)^2} dx\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

2.1.306 Problem 310

Internal problem ID [9478]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 310
Date solved : `Monday, January 27, 2025 at 06:03:15 PM`
CAS classification : `[_Gegenbauer]`

Solve

$$\left(-x^2+1\right) y''-2xy'+12y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.276 (sec)

Writing the ode as

$$\left(-x^2+1\right) y''-2xy'+12y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= -x^2+1 \\ B &= -2x \\ C &= 12 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r=\frac{12x^2-13}{\left(x^2-1\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 12x^2-13 \\ t &= \left(x^2-1\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{12x^2-13}{\left(x^2-1\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.580: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (x^2-1)^2$. There is a pole at $x = 1$ of order 2. There is a pole at $x = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{25}{4(x-1)} - \frac{1}{4(x-1)^2} - \frac{1}{4(x+1)^2} - \frac{25}{4(x+1)}$$

For the pole at $x = 1$ let b be the coefficient of $\frac{1}{(x-1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

For the pole at $x = -1$ let b be the coefficient of $\frac{1}{(x+1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{12x^2 - 13}{(x^2 - 1)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = 12$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = 4 \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -3
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{12x^2 - 13}{(x^2 - 1)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
1	2	0	$\frac{1}{2}$	$\frac{1}{2}$
-1	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	4	-3

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = 4$ then

$$\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^- + \alpha_{c_2}^-\right) \\
&= 4 - (1) \\
&= 3
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x - c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x - c_2} \right) + (+)[\sqrt{r}]_\infty \\
&= \frac{1}{2x-2} + \frac{1}{2x+2} + (0) \\
&= \frac{1}{2x-2} + \frac{1}{2x+2} \\
&= \frac{x}{x^2 - 1}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 3$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x^3 + a_2x^2 + a_1x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(6x + 2a_2) + 2\left(\frac{1}{2x-2} + \frac{1}{2x+2}\right)(3x^2 + 2xa_2 + a_1) + \left(\left(-\frac{1}{2(x-1)^2} - \frac{1}{2(x+1)^2}\right) + \left(\frac{1}{2x-2} + \frac{1}{2x+}\right.\right.$$

$$\frac{-6a_2x^2 + (-10a_1 -}{x^2 -}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\left\{a_0 = 0, a_1 = -\frac{3}{5}, a_2 = 0\right\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^3 - \frac{3}{5}x$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= pe^{\int \omega\,dx} \\
&= \left(x^3 - \frac{3}{5}x\right) e^{\int \left(\frac{1}{2x-2} + \frac{1}{2x+2}\right)dx} \\
&= \left(x^3 - \frac{3}{5}x\right) \sqrt{(x-1)(x+1)} \\
&= \frac{(5x^3 - 3x)\sqrt{x^2-1}}{5}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-2x}{-x^2+1}\,dx} \\
&= z_1 e^{-\frac{\ln(x-1)}{2} - \frac{\ln(x+1)}{2}} \\
&= z_1 \left(\frac{1}{\sqrt{x-1}\,\sqrt{x+1}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{(5x^3 - 3x)\sqrt{x^2-1}}{5\sqrt{x-1}\,\sqrt{x+1}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-2x}{-x^2+1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\ln(x-1) - \ln(x+1)}}{(y_1)^2}\,dx \\
&= y_1 \left(-\frac{25\ln(x+1)}{8} + \frac{125x}{36\left(x^2 - \frac{3}{5}\right)} + \frac{25\ln(x-1)}{8} + \frac{25}{9x}\right)
\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1y_1 + c_2y_2 \\
&= c_1\left(\frac{(5x^3-3x)\sqrt{x^2-1}}{5\sqrt{x-1}\,\sqrt{x+1}}\right) \\
&\quad + c_2\left(\frac{(5x^3-3x)\sqrt{x^2-1}}{5\sqrt{x-1}\,\sqrt{x+1}}\left(-\frac{25\ln(x+1)}{8} + \frac{125x}{36\left(x^2-\frac{3}{5}\right)} + \frac{25\ln(x-1)}{8} + \frac{25}{9x}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$(-x^2+1)\left(\frac{d^2}{dx^2}y(x)\right) - 2x\left(\frac{d}{dx}y(x)\right) + 12y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = \frac{12y(x)}{x^2-1} - \frac{2\left(\frac{d}{dx}y(x)\right)x}{x^2-1}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x) + \frac{2\left(\frac{d}{dx}y(x)\right)x}{x^2-1} - \frac{12y(x)}{x^2-1} = 0$

☐ Check to see if x_0 is a regular singular point

  ◦ Define functions

  $\left[P_2(x) = \frac{2x}{x^2-1}, P_3(x) = -\frac{12}{x^2-1}\right]$

  ◦ $(x+1)\cdot P_2(x)$ is analytic at $x=-1$

  $\left((x+1)\cdot P_2(x)\right)\Big|_{x=-1} = 1$

  ◦ $(x+1)^2\cdot P_3(x)$ is analytic at $x=-1$

  $\left((x+1)^2\cdot P_3(x)\right)\Big|_{x=-1} = 0$

  ◦ $x=-1$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = -1$

- Multiply by denominators

  $(x^2-1)\left(\frac{d^2}{dx^2}y(x)\right) + 2x\left(\frac{d}{dx}y(x)\right) - 12y(x) = 0$

- Change variables using $x = u-1$ so that the regular singular point is at $u=0$

  $(u^2-2u)\left(\frac{d^2}{du^2}y(u)\right) + (2u-2)\left(\frac{d}{du}y(u)\right) - 12y(u) = 0$

- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

☐ Rewrite ODE with series expansions

  ◦ Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$

  $u^m\cdot\left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,u^{k+r-1+m}$

  ◦ Shift index using $k->k+1-m$

  $u^m\cdot\left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,u^{k+r}$

- ∘ Convert $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m = 1..2$

  $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, u^{k+r-2+m}$
- ∘ Shift index using $k- > k+2-m$

  $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\, u^{k+r}$

  Rewrite ODE with series expansions

  $-2a_0r^2u^{-1+r} + \left(\sum_{k=0}^{\infty} \left(-2a_{k+1}(k+1+r)^2 + a_k(k+r+4)(k+r-3)\right) u^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $-2r^2 = 0$
- Values of r that satisfy the indicial equation

  $r = 0$
- Each term in the series must be 0, giving the recursion relation

  $-2a_{k+1}(k+1)^2 + a_k(k+4)(k-3) = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+1} = \frac{a_k(k+4)(k-3)}{2(k+1)^2}$
- Recursion relation for $r = 0$; series terminates at $k = 3$

  $a_{k+1} = \frac{a_k(k+4)(k-3)}{2(k+1)^2}$
- Apply recursion relation for $k = 0$

  $a_1 = -6a_0$
- Apply recursion relation for $k = 1$

  $a_2 = -\frac{5a_1}{4}$
- Express in terms of a_0

  $a_2 = \frac{15a_0}{2}$
- Apply recursion relation for $k = 2$

  $a_3 = -\frac{a_2}{3}$
- Express in terms of a_0

  $a_3 = -\frac{5a_0}{2}$
- Terminating series solution of the ODE for $r = 0$. Use reduction of order to find the second linea

  $y(u) = a_0 \cdot \left(1 - 6u + \frac{15}{2}u^2 - \frac{5}{2}u^3\right)$
- Revert the change of variables $u = x + 1$

  $\left[y(x) = a_0\left(\frac{3}{2}x - \frac{5}{2}x^3\right)\right]$

2.1.307 Problem 311

Internal problem ID [9479]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 311
Date solved : Monday, January 27, 2025 at 06:03:16 PM
CAS classification : [[_2nd_order, _with_linear_symmetries]]

Solve

$$x(x+2)\,y''+2(x+1)\,y'-2y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.220 (sec)

Writing the ode as

$$\left(x^2+2x\right)y''+(2x+2)\,y'-2y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=x^2+2x\\B&=2x+2\\C&=-2\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned}r&=\frac{s}{t}\\&=\frac{2AB'-2BA'+B^2-4AC}{4A^2}\end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{2x^2+4x-1}{\left(x^2+2x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned}s&=2x^2+4x-1\\t&=\left(x^2+2x\right)^2\end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{2x^2+4x-1}{\left(x^2+2x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.582: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (x^2 + 2x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -2$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4(x+2)^2} - \frac{1}{4x^2} + \frac{5}{4x} - \frac{5}{4(x+2)}$$

For the pole at $x = -2$ let b be the coefficient of $\frac{1}{(x+2)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{2x^2+4x-1}{(x^2+2x)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = 2$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -1
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{2x^2+4x-1}{(x^2+2x)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
-2	2	0	$\frac{1}{2}$	$\frac{1}{2}$
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	2	-1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = 2$ then

$$\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^+ + \alpha_{c_2}^+\right) \\
&= 2 - (1) \\
&= 1
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1} \right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x-c_2} \right) + (+)[\sqrt{r}]_\infty \\
&= \frac{1}{2x+4} + \frac{1}{2x} + (0) \\
&= \frac{1}{2x+4} + \frac{1}{2x} \\
&= \frac{x+1}{x(x+2)}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{2x+4} + \frac{1}{2x}\right)(1) + \left(\left(-\frac{1}{2(x+2)^2} - \frac{1}{2x^2}\right) + \left(\frac{1}{2x+4} + \frac{1}{2x}\right)^2 - \left(\frac{2x^2+4x-1}{(x^2+2x)^2}\right)\right) = 0$$

$$\frac{2-2a_0}{x(x+2)} = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 1\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x + 1$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= (x+1)\, e^{\int \left(\frac{1}{2x+4} + \frac{1}{2x}\right) dx} \\ &= (x+1)\sqrt{x(x+2)} \\ &= (x+1)\sqrt{x(x+2)} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{2x+2}{x^2+2x} \, dx} \\ &= z_1 e^{-\frac{\ln(x(x+2))}{2}} \\ &= z_1 \left(\frac{1}{\sqrt{x(x+2)}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = x + 1$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{2x+2}{x^2+2x} \, dx}}{(y_1)^2} \, dx \\ &= y_1 \int \frac{e^{-\ln(x(x+2))}}{(y_1)^2} \, dx \\ &= y_1 \left(\frac{1}{x+1} + \frac{\ln(x)}{2} - \frac{\ln(x+2)}{2}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(x+1) + c_2\left(x + 1\left(\frac{1}{x+1} + \frac{\ln(x)}{2} - \frac{\ln(x+2)}{2}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x(x+2)\left(\frac{d^2}{dx^2}y(x)\right)+2(x+1)\left(\frac{d}{dx}y(x)\right)-2y(x)=0$

- Highest derivative means the order of the ODE is 2

$\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

$\frac{d^2}{dx^2}y(x)=-\frac{2(x+1)\left(\frac{d}{dx}y(x)\right)}{x(x+2)}+\frac{2y(x)}{x(x+2)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

$\frac{d^2}{dx^2}y(x)-\frac{2y(x)}{x(x+2)}+\frac{2(x+1)\left(\frac{d}{dx}y(x)\right)}{x(x+2)}=0$

- □ Check to see if x_0 is a regular singular point
  - Define functions

    $\left[P_2(x)=\frac{2(x+1)}{x(x+2)},P_3(x)=-\frac{2}{x(x+2)}\right]$
  - $(x+2)\cdot P_2(x)$ is analytic at $x=-2$

    $\left.((x+2)\cdot P_2(x))\right|_{x=-2}=1$
  - $(x+2)^2\cdot P_3(x)$ is analytic at $x=-2$

    $\left.((x+2)^2\cdot P_3(x))\right|_{x=-2}=0$
  - $x=-2$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=-2$
- Multiply by denominators

$x(x+2)\left(\frac{d^2}{dx^2}y(x)\right)+(2x+2)\left(\frac{d}{dx}y(x)\right)-2y(x)=0$

- Change variables using $x=u-2$ so that the regular singular point is at $u=0$

$(u^2-2u)\left(\frac{d^2}{du^2}y(u)\right)+(2u-2)\left(\frac{d}{du}y(u)\right)-2y(u)=0$

- Assume series solution for $y(u)$

$y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

- □ Rewrite ODE with series expansions
  - Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$

    $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,u^{k+r-1+m}$
  - Shift index using $k->k+1-m$

    $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,u^{k+r}$
  - Convert $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m=1..2$

    $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)(k+r-1)\,u^{k+r-2+m}$
  - Shift index using $k->k+2-m$

    $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=-2+m}^{\infty}a_{k+2-m}(k+2-m+r)(k+1-m+r)\,u^{k+r}$

  Rewrite ODE with series expansions

  $-2a_0r^2u^{-1+r}+\left(\sum_{k=0}^{\infty}\left(-2a_{k+1}(k+1+r)^2+a_k(k+r+2)(k+r-1)\right)u^{k+r}\right)=0$
- $a_0$cannot be 0 by assumption, giving the indicial equation

$-2r^2 = 0$

- Values of r that satisfy the indicial equation

  $r = 0$

- Each term in the series must be 0, giving the recursion relation

  $-2a_{k+1}(k+1)^2 + a_k(k+2)(k-1) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+1} = \frac{a_k(k+2)(k-1)}{2(k+1)^2}$

- Recursion relation for $r = 0$; series terminates at $k = 1$

  $a_{k+1} = \frac{a_k(k+2)(k-1)}{2(k+1)^2}$

- Apply recursion relation for $k = 0$

  $a_1 = -a_0$

2.1.308 Problem 313

Internal problem ID [9480]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 313
Date solved : Monday, January 27, 2025 at 06:03:17 PM
CAS classification :
[[_2nd_order, _with_linear_symmetries], [_2nd_order, _linear, '_with_symmetry_[0,F(x)]']]

Solve

$$x(x+2)\,y''+(x+1)\,y'-4y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.208 (sec)

Writing the ode as

$$\left(x^2+2x\right)y''+(x+1)\,y'-4y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=x^2+2x\\B&=x+1\\C&=-4\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned}r&=\frac{s}{t}\\&=\frac{2AB'-2BA'+B^2-4AC}{4A^2}\end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{15x^2+30x-3}{4\left(x^2+2x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned}s&=15x^2+30x-3\\t&=4\left(x^2+2x\right)^2\end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{15x^2+30x-3}{4\left(x^2+2x\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.584: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4-2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^2+2x)^2$. There is a pole at $x=0$ of order 2. There is a pole at $x=-2$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1,2,4,6,12]$$

Attempting to find a solution using case $n=1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{33}{16\,(x+2)} - \frac{3}{16x^2} - \frac{3}{16\,(x+2)^2} + \frac{33}{16x}$$

For the pole at $x=-2$ let b be the coefficient of $\frac{1}{(x+2)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{4} \end{aligned}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{4} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{4}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = \frac{15x^2 + 30x - 3}{4\left(x^2 + 2x\right)^2}
$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{15}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{15x^2 + 30x - 3}{4\left(x^2 + 2x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
-2	2	0	$\frac{3}{4}$	$\frac{1}{4}$
0	2	0	$\frac{3}{4}$	$\frac{1}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{5}{2}$	$-\frac{3}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{5}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^+ + \alpha_{c_2}^+\right) \\
&= \frac{5}{2} - \left(\frac{3}{2}\right) \\
&= 1
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

Substituting the above values in the above results in

$$
\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x-c_1}\right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{+}}{x-c_2}\right) + (+)[\sqrt{r}]_{\infty} \\
&= \frac{3}{4(x+2)} + \frac{3}{4x} + (0) \\
&= \frac{3}{4(x+2)} + \frac{3}{4x} \\
&= \frac{\frac{3x}{2}+\frac{3}{2}}{x(x+2)}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}
$$

Let

$$
p(x) = x + a_0 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(0) + 2\left(\frac{3}{4(x+2)} + \frac{3}{4x}\right)(1) + \left(\left(-\frac{3}{4(x+2)^2} - \frac{3}{4x^2}\right) + \left(\frac{3}{4(x+2)} + \frac{3}{4x}\right)^2 - \left(\frac{15x^2+30x-3}{4(x^2+2x)^2}\right)\right) = \frac{3-3a_0}{x(x+2)} = 0
$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$
\{a_0 = 1\}
$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$
p(x) = x + 1
$$

Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= (x+1)\, e^{\int \left(\frac{3}{4(x+2)} + \frac{3}{4x}\right) dx} \\
&= (x+1)\,(x(x+2))^{3/4} \\
&= (x+1)\,(x(x+2))^{3/4}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{x+1}{x^2+2x} \, dx} \\
&= z_1 e^{-\frac{\ln(x(x+2))}{4}} \\
&= z_1 \left(\frac{1}{(x(x+2))^{1/4}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \sqrt{x(x+2)}\,(x+1)
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx
$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x+1}{x^2+2x}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{\ln(x(x+2))}{2}}}{(y_1)^2}\,dx \\
&= y_1 \left(-\frac{2x^2+4x+1}{\sqrt{x\,(x+2)}\,(x+1)}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\sqrt{x\,(x+2)}\,(x+1)\right) + c_2 \left(\sqrt{x\,(x+2)}\,(x+1)\left(-\frac{2x^2+4x+1}{\sqrt{x\,(x+2)}\,(x+1)}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x(x+2)\left(\frac{d^2}{dx^2}y(x)\right) + (x+1)\left(\frac{d}{dx}y(x)\right) - 4y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = \frac{4y(x)}{x(x+2)} - \frac{(x+1)\left(\frac{d}{dx}y(x)\right)}{x(x+2)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x) + \frac{(x+1)\left(\frac{d}{dx}y(x)\right)}{x(x+2)} - \frac{4y(x)}{x(x+2)} = 0$

- ☐ Check to see if x_0 is a regular singular point
  - Define functions

    $\left[P_2(x) = \frac{x+1}{x(x+2)}, P_3(x) = -\frac{4}{x(x+2)}\right]$

  - $(x+2)\cdot P_2(x)$ is analytic at $x=-2$

    $\left.\left((x+2)\cdot P_2(x)\right)\right|_{x=-2} = \frac{1}{2}$

  - $(x+2)^2\cdot P_3(x)$ is analytic at $x=-2$

    $\left.\left((x+2)^2\cdot P_3(x)\right)\right|_{x=-2} = 0$

  - $x=-2$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = -2$

- Multiply by denominators

  $x(x+2)\left(\frac{d^2}{dx^2}y(x)\right) + (x+1)\left(\frac{d}{dx}y(x)\right) - 4y(x) = 0$

- Change variables using $x = u-2$ so that the regular singular point is at $u=0$

  $(u^2-2u)\left(\frac{d^2}{du^2}y(u)\right) + (u-1)\left(\frac{d}{du}y(u)\right) - 4y(u) = 0$

- Assume series solution for $y(u)$

$y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

- □ Rewrite ODE with series expansions
  - ○ Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..1$

    $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, u^{k+r-1+m}$
  - ○ Shift index using $k->k+1-m$

    $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$
  - ○ Convert $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m = 1..2$

    $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, u^{k+r-2+m}$
  - ○ Shift index using $k->k+2-m$

    $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, u^{k+r}$

  Rewrite ODE with series expansions

  $-a_0r(-1+2r)\, u^{-1+r} + \left(\sum_{k=0}^{\infty} \left(-a_{k+1}(k+1+r)\,(2k+1+2r) + a_k(k+r+2)\,(k+r-2)\right) u^{k+r}\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $-r(-1+2r) = 0$
- Values of r that satisfy the indicial equation

  $r \in \left\{0, \frac{1}{2}\right\}$
- Each term in the series must be 0, giving the recursion relation

  $-2(k+1+r)\left(k+r+\frac{1}{2}\right) a_{k+1} + a_k(k+r+2)\,(k+r-2) = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+1} = \frac{a_k(k+r+2)(k+r-2)}{(k+1+r)(2k+1+2r)}$
- Recursion relation for $r = 0$; series terminates at $k = 2$

  $a_{k+1} = \frac{a_k(k+2)(k-2)}{(k+1)(2k+1)}$
- Apply recursion relation for $k = 0$

  $a_1 = -4a_0$
- Apply recursion relation for $k = 1$

  $a_2 = -\frac{a_1}{2}$
- Express in terms of a_0

  $a_2 = 2a_0$
- Terminating series solution of the ODE for $r = 0$. Use reduction of order to find the second li

  $y(u) = a_0 \cdot (2u^2 - 4u + 1)$
- Revert the change of variables $u = x + 2$

  $[y(x) = a_0(2x^2 + 4x + 1)]$
- Recursion relation for $r = \frac{1}{2}$

  $a_{k+1} = \frac{a_k\left(k+\frac{5}{2}\right)\left(k-\frac{3}{2}\right)}{\left(k+\frac{3}{2}\right)(2k+2)}$
- Solution for $r = \frac{1}{2}$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+\frac{1}{2}}, a_{k+1} = \frac{a_k\left(k+\frac{5}{2}\right)\left(k-\frac{3}{2}\right)}{\left(k+\frac{3}{2}\right)(2k+2)}\right]$
- Revert the change of variables $u = x + 2$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k(x+2)^{k+\frac{1}{2}}, a_{k+1} = \frac{a_k\left(k+\frac{5}{2}\right)\left(k-\frac{3}{2}\right)}{\left(k+\frac{3}{2}\right)(2k+2)}\right]$
- Combine solutions and rename parameters

$$\left[y(x)=a_0(2x^2+4x+1)+\left(\sum_{k=0}^{\infty} b_k(x+2)^{k+\frac{1}{2}}\right), b_{k+1}=\frac{b_k\left(k+\frac{5}{2}\right)\left(k-\frac{3}{2}\right)}{\left(k+\frac{3}{2}\right)(2k+2)}\right]$$

2.1.309 Problem 314

Internal problem ID [9481]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 314
Date solved : `Monday, January 27, 2025 at 06:03:17 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$(x-1)\,y''-xy'+y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.227 (sec)

Writing the ode as

$$(x-1)\,y''-xy'+y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x-1 \\ B &= -x \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{x^2-4x+6}{4\,(x-1)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2-4x+6 \\ t &= 4(x-1)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{x^2-4x+6}{4\,(x-1)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.586: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x-1)^2$. There is a pole at $x = 1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} + \frac{3}{4\,(x-1)^2} - \frac{1}{2\,(x-1)}$$

For the pole at $x = 1$ let b be the coefficient of $\frac{1}{(x-1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} - \frac{1}{2x} + \frac{1}{x^3} + \frac{11}{4x^4} + \frac{21}{4x^5} + \frac{15}{2x^6} + \frac{6}{x^7} - \frac{117}{16x^8} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 - 4x + 6}{4x^2 - 8x + 4} \\ &= Q + \frac{R}{4x^2 - 8x + 4} \\ &= \left(\frac{1}{4}\right) + \left(\frac{-2x + 5}{4x^2 - 8x + 4}\right) \\ &= \frac{1}{4} + \frac{-2x + 5}{4x^2 - 8x + 4} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is -2. Dividing this by leading coefficient in t which is 4 gives $-\frac{1}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{1}{2}\right) - (0) \\ &= -\frac{1}{2} \end{aligned}$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \frac{1}{2} \\
\alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &= -\frac{1}{2} \\
\alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) = \frac{1}{2}\left(-\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) = \frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{x^2 - 4x + 6}{4\left(x-1\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
1	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	$-\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = -\frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^-\right) \\
&= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty
$$

Substituting the above values in the above results in

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + (+)[\sqrt{r}]_\infty \\
&= -\frac{1}{2\left(x-1\right)} + \left(\frac{1}{2}\right) \\
&= -\frac{1}{2\left(x-1\right)} + \frac{1}{2} \\
&= \frac{x-2}{2x-2}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(-\frac{1}{2(x-1)}+\frac{1}{2}\right)(0)+\left(\left(\frac{1}{2(x-1)^2}\right)+\left(-\frac{1}{2(x-1)}+\frac{1}{2}\right)^2-\left(\frac{x^2-4x+6}{4(x-1)^2}\right)\right)=0$$
$$0=0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z''=rz$ is

$$\begin{aligned}
z_1(x) &= pe^{\int \omega\,dx}\\
&= \mathrm{e}^{\int\left(-\frac{1}{2(x-1)}+\frac{1}{2}\right)dx}\\
&= \frac{\mathrm{e}^{\frac{x}{2}}}{\sqrt{x-1}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}\\
&= z_1 e^{-\int \frac{1}{2}\frac{-x}{x-1}\,dx}\\
&= z_1 e^{\frac{x}{2}+\frac{\ln(x-1)}{2}}\\
&= z_1\left(\sqrt{x-1}\,\mathrm{e}^{\frac{x}{2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1\int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1\int \frac{e^{\int -\frac{-x}{x-1}\,dx}}{(y_1)^2}\,dx\\
&= y_1\int \frac{e^{x+\ln(x-1)}}{(y_1)^2}\,dx\\
&= y_1\left(-\frac{x\,\mathrm{e}^{x+\ln(x-1)}\mathrm{e}^{-2x}}{x-1}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1y_1+c_2y_2\\
&= c_1(\mathrm{e}^{x})+c_2\left(\mathrm{e}^{x}\left(-\frac{x\,\mathrm{e}^{x+\ln(x-1)}\mathrm{e}^{-2x}}{x-1}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$(x-1)\left(\frac{d^2}{dx^2}y(x)\right)-x\left(\frac{d}{dx}y(x)\right)+y(x)=0$

- Highest derivative means the order of the ODE is 2

$\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

$\frac{d^2}{dx^2}y(x)=-\frac{y(x)}{x-1}+\frac{\left(\frac{d}{dx}y(x)\right)x}{x-1}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

$\frac{d^2}{dx^2}y(x)-\frac{\left(\frac{d}{dx}y(x)\right)x}{x-1}+\frac{y(x)}{x-1}=0$

□ Check to see if $x_0=1$ is a regular singular point

  ◦ Define functions

  $\left[P_2(x)=-\frac{x}{x-1},P_3(x)=\frac{1}{x-1}\right]$

  ◦ $(x-1)\cdot P_2(x)$ is analytic at $x=1$

  $\left((x-1)\cdot P_2(x)\right)\Big|_{x=1}=-1$

  ◦ $(x-1)^2\cdot P_3(x)$ is analytic at $x=1$

  $\left((x-1)^2\cdot P_3(x)\right)\Big|_{x=1}=0$

  ◦ $x=1$is a regular singular point

Check to see if $x_0=1$ is a regular singular point

$x_0=1$

- Multiply by denominators

$(x-1)\left(\frac{d^2}{dx^2}y(x)\right)-x\left(\frac{d}{dx}y(x)\right)+y(x)=0$

- Change variables using $x=u+1$ so that the regular singular point is at $u=0$

$u\left(\frac{d^2}{du^2}y(u)\right)+(-u-1)\left(\frac{d}{du}y(u)\right)+y(u)=0$

- Assume series solution for $y(u)$

$y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$

  $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,u^{k+r-1+m}$

  ◦ Shift index using $k->k+1-m$

  $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,u^{k+r}$

  ◦ Convert $u\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion

  $u\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)(k+r-1)\,u^{k+r-1}$

  ◦ Shift index using $k->k+1$

  $u\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=-1}^{\infty}a_{k+1}(k+1+r)(k+r)\,u^{k+r}$

Rewrite ODE with series expansions

$a_0r(-2+r)\,u^{-1+r}+\left(\sum_{k=0}^{\infty}\left(a_{k+1}(k+1+r)(k+r-1)-a_k(k+r-1)\right)u^{k+r}\right)=0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$r(-2+r)=0$

- Values of r that satisfy the indicial equation
$r \in \{0, 2\}$
- Each term in the series must be 0, giving the recursion relation
$(k+r-1)\left(a_{k+1}(k+1+r)-a_k\right)=0$
- Recursion relation that defines series solution to ODE
$a_{k+1}=\frac{a_k}{k+1+r}$
- Recursion relation for $r=0$
$a_{k+1}=\frac{a_k}{k+1}$
- Solution for $r=0$
$\left[y(u)=\sum_{k=0}^{\infty} a_k u^k, a_{k+1}=\frac{a_k}{k+1}\right]$
- Revert the change of variables $u=x-1$
$\left[y(x)=\sum_{k=0}^{\infty} a_k (x-1)^k, a_{k+1}=\frac{a_k}{k+1}\right]$
- Recursion relation for $r=2$
$a_{k+1}=\frac{a_k}{k+3}$
- Solution for $r=2$
$\left[y(u)=\sum_{k=0}^{\infty} a_k u^{k+2}, a_{k+1}=\frac{a_k}{k+3}\right]$
- Revert the change of variables $u=x-1$
$\left[y(x)=\sum_{k=0}^{\infty} a_k (x-1)^{k+2}, a_{k+1}=\frac{a_k}{k+3}\right]$
- Combine solutions and rename parameters
$\left[y(x)=\left(\sum_{k=0}^{\infty} a_k (x-1)^k\right)+\left(\sum_{k=0}^{\infty} b_k (x-1)^{k+2}\right), a_{k+1}=\frac{a_k}{k+1}, b_{k+1}=\frac{b_k}{k+3}\right]$

CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$\left(x^2+1\right) y''-2xy'+2y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.267 (sec)

Writing the ode as

$$\left(x^2+1\right) y''-2xy'+2y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2+1 \\ B &= -2x \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{-3}{\left(x^2+1\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -3 \\ t &= \left(x^2+1\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(-\frac{3}{\left(x^2+1\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.588: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 0 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (x^2 + 1)^2$. There is a pole at $x = i$ of order 2. There is a pole at $x = -i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{3}{4(x-i)^2} + \frac{3}{4(x+i)^2} + \frac{3i}{4(x-i)} - \frac{3i}{4(x+i)}$$

For the pole at $x = i$ let b be the coefficient of $\frac{1}{(x-i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

For the pole at $x = -i$ let b be the coefficient of $\frac{1}{(x+i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $4 > 2$ then

$$\begin{aligned}[\sqrt{r}]_\infty &= 0\\ \alpha_\infty^+ &= 0\\ \alpha_\infty^- &= 1\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = -\frac{3}{(x^2+1)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
i	2	0	$\frac{3}{2}$	$-\frac{1}{2}$
$-i$	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$ then

$$\begin{aligned}d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^+\right)\\ &= 1 - (1)\\ &= 0\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x-c_2}\right) + (-)[\sqrt{r}]_\infty\\ &= -\frac{1}{2\,(x-i)} + \frac{3}{2\,(x+i)} + (-)\,(0)\\ &= -\frac{1}{2\,(x-i)} + \frac{3}{2\,(x+i)}\\ &= \frac{x-2i}{x^2+1}\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(-\frac{1}{2\left(x-i\right)}+\frac{3}{2\left(x+i\right)}\right)(0)+\left(\left(\frac{1}{2\left(x-i\right)^{2}}-\frac{3}{2\left(x+i\right)^{2}}\right)+\left(-\frac{1}{2\left(x-i\right)}+\frac{3}{2\left(x+i\right)}\right)^{2}-\left(-\frac{}{(x^2}\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z''=rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega\,dx} \\
&= e^{\int \left(-\frac{1}{2(x-i)}+\frac{3}{2(x+i)}\right)dx} \\
&= \frac{\left(x^2+1\right)^{3/2}}{\left(ix+1\right)^2}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-2x}{x^2+1}\,dx} \\
&= z_1 e^{\frac{\ln\left(x^2+1\right)}{2}} \\
&= z_1\left(\sqrt{x^2+1}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{\left(x^2+1\right)^2}{\left(ix+1\right)^2}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-2x}{x^2+1}\,dx}}{\left(y_1\right)^2}\,dx \\
&= y_1 \int \frac{e^{\ln\left(x^2+1\right)}}{\left(y_1\right)^2}\,dx \\
&= y_1\left(-\frac{x}{\left(x+i\right)^2}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{\left(x^2+1\right)^2}{\left(ix+1\right)^2}\right) + c_2\left(\frac{\left(x^2+1\right)^2}{\left(ix+1\right)^2}\left(-\frac{x}{\left(x+i\right)^2}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

2.1.311 Problem 316

Internal problem ID [9483]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 316
Date solved : `Monday, January 27, 2025 at 06:03:19 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$\left(x^2-2x+10\right)y''+xy'-4y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.354 (sec)

Writing the ode as

$$\left(x^2-2x+10\right)y''+xy'-4y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2-2x+10 \\ B &= x \\ C &= -4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{15x^2-32x+180}{4\left(x^2-2x+10\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 15x^2-32x+180 \\ t &= 4\left(x^2-2x+10\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{15x^2-32x+180}{4\left(x^2-2x+10\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.589: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^2 - 2x + 10)^2$. There is a pole at $x = 1 + 3i$ of order 2. There is a pole at $x = 1 - 3i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{-\frac{7}{36} + \frac{i}{24}}{(x - 1 - 3i)^2} + \frac{-\frac{7}{36} - \frac{i}{24}}{(x - 1 + 3i)^2} - \frac{149i}{216\,(x - 1 - 3i)} + \frac{149i}{216\,(x - 1 + 3i)}$$

For the pole at $x = 1 + 3i$ let b be the coefficient of $\frac{1}{(x-1-3i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{7}{36} + \frac{i}{24}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{3}{4} + \frac{i}{12} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{4} - \frac{i}{12} \end{aligned}$$

For the pole at $x = 1 - 3i$ let b be the coefficient of $\frac{1}{(x-1+3i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{7}{36} - \frac{i}{24}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{3}{4} - \frac{i}{12} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{4} + \frac{i}{12} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{15x^2 - 32x + 180}{4\left(x^2 - 2x + 10\right)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{15}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{2}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{15x^2 - 32x + 180}{4\left(x^2 - 2x + 10\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
$1+3i$	2	0	$\frac{3}{4} + \frac{i}{12}$	$\frac{1}{4} - \frac{i}{12}$
$1-3i$	2	0	$\frac{3}{4} - \frac{i}{12}$	$\frac{1}{4} + \frac{i}{12}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{5}{2}$	$-\frac{3}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{5}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^+ + \alpha_{c_2}^+\right) \\
&= \frac{5}{2} - \left(\frac{3}{2}\right) \\
&= 1
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1} \right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x-c_2} \right) + (+)[\sqrt{r}]_\infty \\
&= \frac{\frac{3}{4} + \frac{i}{12}}{x-1-3i} + \frac{\frac{3}{4} - \frac{i}{12}}{x-1+3i} + (0) \\
&= \frac{\frac{3}{4} + \frac{i}{12}}{x-1-3i} + \frac{\frac{3}{4} - \frac{i}{12}}{x-1+3i} \\
&= \frac{3x-4}{2x^2-4x+20}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{\frac{3}{4} + \frac{i}{12}}{x - 1 - 3i} + \frac{\frac{3}{4} - \frac{i}{12}}{x - 1 + 3i}\right)(1) + \left(\left(\frac{-\frac{3}{4} - \frac{i}{12}}{(x - 1 - 3i)^2} + \frac{-\frac{3}{4} + \frac{i}{12}}{(x - 1 + 3i)^2}\right) + \left(\frac{\frac{3}{4} + \frac{i}{12}}{x - 1 - 3i} + \frac{\frac{3}{4} - \frac{i}{12}}{x - 1 + 3i \ldots}\right.\right.$$

$$- \frac{3}{(- \ldots}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\left\{a_0 = -\frac{4}{3}\right\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x - \frac{4}{3}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \left(x - \frac{4}{3}\right) e^{\int \left(\frac{\frac{3}{4} + \frac{i}{12}}{x - 1 - 3i} + \frac{\frac{3}{4} - \frac{i}{12}}{x - 1 + 3i}\right) dx} \\
&= \left(x - \frac{4}{3}\right) e^{\frac{3 \ln\left(x^2 - 2x + 10\right)}{4} - \frac{\arctan\left(\frac{x}{3} - \frac{1}{3}\right)}{6}} \\
&= \frac{(3x - 4)\left(x^2 - 2x + 10\right)^{3/4} e^{-\frac{\arctan\left(\frac{x}{3} - \frac{1}{3}\right)}{6}}}{3}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{x}{x^2 - 2x + 10} \, dx} \\
&= z_1 e^{-\frac{\ln\left(x^2 - 2x + 10\right)}{4} - \frac{\arctan\left(\frac{x}{3} - \frac{1}{3}\right)}{6}} \\
&= z_1 \left(\frac{e^{-\frac{\arctan\left(\frac{x}{3} - \frac{1}{3}\right)}{6}}}{\left(x^2 - 2x + 10\right)^{1/4}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{\sqrt{x^2 - 2x + 10}\, e^{-\frac{\arctan\left(\frac{x}{3} - \frac{1}{3}\right)}{3}} (3x - 4)}{3}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x}{x^2-2x+10} dx}}{(y_1)^2} dx \\
&= y_1 \int \frac{e^{-\frac{\ln(x^2-2x+10)}{2}-\frac{\arctan\left(\frac{x}{3}-\frac{1}{3}\right)}{3}}}{(y_1)^2} dx \\
&= y_1 \left(-\frac{9(3x^2-4x+15)\,\mathrm{e}^{-\frac{\ln(x^2-2x+10)}{2}-\frac{\arctan\left(\frac{x}{3}-\frac{1}{3}\right)}{3}}\,\mathrm{e}^{\frac{2\arctan\left(\frac{x}{3}-\frac{1}{3}\right)}{3}}}{410\,(3x-4)}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{\sqrt{x^2-2x+10}\,\mathrm{e}^{-\frac{\arctan\left(\frac{x}{3}-\frac{1}{3}\right)}{3}}(3x-4)}{3}\right) \\
&\quad + c_2 \left(\frac{\sqrt{x^2-2x+10}\,\mathrm{e}^{-\frac{\arctan\left(\frac{x}{3}-\frac{1}{3}\right)}{3}}(3x-4)}{3}\left(-\frac{9(3x^2-4x+15)\,\mathrm{e}^{-\frac{\ln(x^2-2x+10)}{2}-\frac{\arctan\left(\frac{x}{3}-\frac{1}{3}\right)}{3}}\,\mathrm{e}^{\frac{2\arctan\left(\frac{x}{3}-\frac{1}{3}\right)}{3}}}{410\,(3x-4)}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Solve

$$\left(x^2-2x+10\right)y''+xy'-4y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.364 (sec)

Writing the ode as

$$\left(x^2-2x+10\right)y''+xy'-4y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2-2x+10 \\ B &= x \\ C &= -4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{15x^2-32x+180}{4\left(x^2-2x+10\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 15x^2-32x+180 \\ t &= 4\left(x^2-2x+10\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{15x^2-32x+180}{4\left(x^2-2x+10\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.590: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^2 - 2x + 10)^2$. There is a pole at $x = 1 + 3i$ of order 2. There is a pole at $x = 1 - 3i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{-\frac{7}{36} + \frac{i}{24}}{(x - 1 - 3i)^2} + \frac{-\frac{7}{36} - \frac{i}{24}}{(x - 1 + 3i)^2} - \frac{149i}{216\,(x - 1 - 3i)} + \frac{149i}{216\,(x - 1 + 3i)}$$

For the pole at $x = 1 + 3i$ let b be the coefficient of $\frac{1}{(x-1-3i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{7}{36} + \frac{i}{24}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{4} + \frac{i}{12} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{4} - \frac{i}{12} \end{aligned}$$

For the pole at $x = 1 - 3i$ let b be the coefficient of $\frac{1}{(x-1+3i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{7}{36} - \frac{i}{24}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{4} - \frac{i}{12} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{4} + \frac{i}{12} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{15x^2 - 32x + 180}{4\left(x^2 - 2x + 10\right)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{15}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{2}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{15x^2 - 32x + 180}{4\left(x^2 - 2x + 10\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
$1+3i$	2	0	$\frac{3}{4} + \frac{i}{12}$	$\frac{1}{4} - \frac{i}{12}$
$1-3i$	2	0	$\frac{3}{4} - \frac{i}{12}$	$\frac{1}{4} + \frac{i}{12}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{5}{2}$	$-\frac{3}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{5}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^+ + \alpha_{c_2}^+\right) \\
&= \frac{5}{2} - \left(\frac{3}{2}\right) \\
&= 1
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1}\right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x-c_2}\right) + (+)[\sqrt{r}]_\infty \\
&= \frac{\frac{3}{4} + \frac{i}{12}}{x-1-3i} + \frac{\frac{3}{4} - \frac{i}{12}}{x-1+3i} + (0) \\
&= \frac{\frac{3}{4} + \frac{i}{12}}{x-1-3i} + \frac{\frac{3}{4} - \frac{i}{12}}{x-1+3i} \\
&= \frac{3x-4}{2x^2-4x+20}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{\frac{3}{4}+\frac{i}{12}}{x-1-3i} + \frac{\frac{3}{4}-\frac{i}{12}}{x-1+3i}\right)(1) + \left(\left(\frac{-\frac{3}{4}-\frac{i}{12}}{\left(x-1-3i\right)^2} + \frac{-\frac{3}{4}+\frac{i}{12}}{\left(x-1+3i\right)^2}\right) + \left(\frac{\frac{3}{4}+\frac{i}{12}}{x-1-3i} + \frac{\frac{3}{4}-\frac{i}{12}}{x-1+3i} \right.\right.$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\left\{a_0 = -\frac{4}{3}\right\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x - \frac{4}{3}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \left(x - \frac{4}{3}\right) e^{\int \left(\frac{\frac{3}{4}+\frac{i}{12}}{x-1-3i} + \frac{\frac{3}{4}-\frac{i}{12}}{x-1+3i}\right) dx} \\
&= \left(x - \frac{4}{3}\right) e^{\frac{3\ln\left(x^2-2x+10\right)}{4} - \frac{\arctan\left(\frac{x}{3}-\frac{1}{3}\right)}{6}} \\
&= \frac{(3x-4)\left(x^2-2x+10\right)^{3/4} e^{-\frac{\arctan\left(\frac{x}{3}-\frac{1}{3}\right)}{6}}}{3}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{x}{x^2-2x+10} \, dx} \\
&= z_1 e^{-\frac{\ln\left(x^2-2x+10\right)}{4} - \frac{\arctan\left(\frac{x}{3}-\frac{1}{3}\right)}{6}} \\
&= z_1 \left(\frac{e^{-\frac{\arctan\left(\frac{x}{3}-\frac{1}{3}\right)}{6}}}{\left(x^2-2x+10\right)^{1/4}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{\sqrt{x^2-2x+10}\, e^{-\frac{\arctan\left(\frac{x}{3}-\frac{1}{3}\right)}{3}} (3x-4)}{3}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x}{x^2-2x+10}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{\ln\left(x^2-2x+10\right)}{2}-\frac{\arctan\left(\frac{x}{3}-\frac{1}{3}\right)}{3}}}{(y_1)^2}\,dx \\
&= y_1\left(-\frac{9(3x^2-4x+15)\,\mathrm{e}^{-\frac{\ln\left(x^2-2x+10\right)}{2}-\frac{\arctan\left(\frac{x}{3}-\frac{1}{3}\right)}{3}}\,\mathrm{e}^{\frac{2\arctan\left(\frac{x}{3}-\frac{1}{3}\right)}{3}}}{410\,(3x-4)}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{\sqrt{x^2-2x+10}\,\mathrm{e}^{-\frac{\arctan\left(\frac{x}{3}-\frac{1}{3}\right)}{3}}(3x-4)}{3}\right) \\

2.1.313 Problem 318

Internal problem ID [9485]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 318
Date solved : `Monday, January 27, 2025 at 06:03:20 PM`
CAS classification : `[_Hermite]`

Solve

$$y'' - xy' + 2y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.231 (sec)

Writing the ode as

$$y'' - xy' + 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -x \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 - 10}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2 - 10 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2}{4} - \frac{5}{2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.591: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 2 \\ &= -2 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x}{2} - \frac{5}{2x} - \frac{25}{4x^3} - \frac{125}{4x^5} - \frac{3125}{16x^7} - \frac{21875}{16x^9} - \frac{328125}{32x^{11}} - \frac{2578125}{32x^{13}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= \frac{x}{2}\end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{x^2}{4}$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned}r &= \frac{s}{t} \\ &= \frac{x^2 - 10}{4} \\ &= Q + \frac{R}{4} \\ &= \left(\frac{x^2}{4} - \frac{5}{2}\right) + (0) \\ &= \frac{x^2}{4} - \frac{5}{2}\end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is $-\frac{5}{2}$. Now b can be found.

$$\begin{aligned}b &= \left(-\frac{5}{2}\right) - (0) \\ &= -\frac{5}{2}\end{aligned}$$

Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= \frac{x}{2} \\ \alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-\frac{5}{2}}{\frac{1}{2}} - 1\right) &= -3 \\ \alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-\frac{5}{2}}{\frac{1}{2}} - 1\right) &= 2\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2}{4} - \frac{5}{2}$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
-2	$\frac{x}{2}$	-3	2

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 2$, and since there are no poles then

$$\begin{aligned} d &= \alpha_\infty^- \\ &= 2 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= (-)[\sqrt{r}]_\infty \\ &= 0 + (-)\left(\frac{x}{2}\right) \\ &= -\frac{x}{2} \\ &= -\frac{x}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 2$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = x^2 + a_1 x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (2) + 2\left(-\frac{x}{2}\right)(2x + a_1) + \left(\left(-\frac{1}{2}\right) + \left(-\frac{x}{2}\right)^2 - \left(\frac{x^2}{4} - \frac{5}{2}\right)\right) &= 0 \\ a_1 x + 2a_0 + 2 &= 0 \end{aligned}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = -1, a_1 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^2 - 1$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega\, dx} \\ &= (x^2 - 1)\, e^{\int -\frac{x}{2} dx} \\ &= (x^2 - 1)\, e^{-\frac{x^2}{4}} \\ &= (x^2 - 1)\, e^{-\frac{x^2}{4}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-x}{1}\, dx} \\ &= z_1 e^{\frac{x^2}{4}} \\ &= z_1\left(e^{\frac{x^2}{4}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = x^2 - 1$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-x}{1}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{\frac{x^2}{2}}}{(y_1)^2}\, dx \\ &= y_1 \left(\int \frac{e^{\frac{x^2}{2}}}{(x^2-1)^2} dx\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 (x^2 - 1) + c_2 \left(x^2 - 1 \left(\int \frac{e^{\frac{x^2}{2}}}{(x^2-1)^2} dx\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$\frac{d^2}{dx^2}y(x) - x\left(\frac{d}{dx}y(x)\right) + 2y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^k$

☐ Rewrite DE with series expansions

- ∘ Convert $x \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion

  $x \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k k\, x^k$

- ∘ Convert $\frac{d^2}{dx^2}y(x)$ to series expansion

  $\frac{d^2}{dx^2}y(x) = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$

- ∘ Shift index using $k- >k+2$

  $\frac{d^2}{dx^2}y(x) = \sum_{k=0}^{\infty} a_{k+2}(k+2)(k+1)\, x^k$

  Rewrite DE with series expansions

  $\sum_{k=0}^{\infty} \left(a_{k+2}(k+2)(k+1) - a_k(k-2)\right) x^k = 0$

- Each term in the series must be 0, giving the recursion relation

  $(k^2 + 3k + 2)\, a_{k+2} - a_k(k-2) = 0$

- Recursion relation; series terminates at $k = 2$

$a_{k+2} = \frac{a_k(k-2)}{k^2+3k+2}$

- Apply recursion relation for $k = 0$

  $a_2 = -a_0$

- Terminating series solution of the ODE. Use reduction of order to find the second linearly ind

  $y(x) = A_2 x^2 + A_1 x - a_0$

2.1.314 Problem 319

Internal problem ID [9486]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 319
Date solved : `Monday, January 27, 2025 at 06:03:21 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$(x+2)\,y''+xy'-y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.253 (sec)

Writing the ode as

$$(x+2)\,y''+xy'-y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A&=x+2\\ B&=x\\ C&=-1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r&=\frac{s}{t} \\ &=\frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{x^2+4x+12}{4\,(x+2)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s&=x^2+4x+12\\ t&=4(x+2)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{x^2+4x+12}{4\,(x+2)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.593: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x+2)^2$. There is a pole at $x = -2$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} + \frac{2}{(x+2)^2}$$

For the pole at $x = -2$ let b be the coefficient of $\frac{1}{(x+2)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1 \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} + \frac{2}{x^2} - \frac{8}{x^3} + \frac{20}{x^4} - \frac{32}{x^5} + \frac{16}{x^6} + \frac{64}{x^7} - \frac{80}{x^8} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 + 4x + 12}{4x^2 + 16x + 16} \\ &= Q + \frac{R}{4x^2 + 16x + 16} \\ &= \left(\frac{1}{4}\right) + \left(\frac{8}{4x^2 + 16x + 16}\right) \\ &= \frac{1}{4} + \frac{8}{4x^2 + 16x + 16} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is 0. Dividing this by leading coefficient in t which is 4 gives 0. Now b can be found.

$$\begin{aligned} b &= (0) - (0) \\ &= 0 \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{2} \\ \alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{0}{\frac{1}{2}} - 0\right) &= 0 \\ \alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{0}{\frac{1}{2}} - 0\right) &= 0 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2 + 4x + 12}{4(x+2)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
-2	2	0	2	-1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	0	0

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 0$ then

$$\begin{aligned} d &= \alpha_\infty^- - (\alpha_{c_1}^-) \\ &= 0 - (-1) \\ &= 1 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= -\frac{1}{x+2} + (-)\left(\frac{1}{2}\right) \\ &= -\frac{1}{x+2} - \frac{1}{2} \\ &= -\frac{4+x}{2(x+2)} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{x+2} - \frac{1}{2}\right)(1) + \left(\left(\frac{1}{(x+2)^2} \right) + \left(-\frac{1}{x+2} - \frac{1}{2} \right)^2 - \left(\frac{x^2+4x+12}{4(x+2)^2} \right) \right) = 0$$

$$\frac{a_0 - 4}{x+2} = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 4\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = 4 + x$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= (4+x)\, \mathrm{e}^{\int \left(-\frac{1}{x+2}-\frac{1}{2}\right) dx} \\ &= (4+x)\, \mathrm{e}^{-\frac{x}{2}-\ln(x+2)} \\ &= \frac{(4+x)\, \mathrm{e}^{-\frac{x}{2}}}{x+2} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{x}{x+2} \, dx} \\ &= z_1 e^{-\frac{x}{2}+\ln(x+2)} \\ &= z_1 \left((x+2)\, \mathrm{e}^{-\frac{x}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-x}(4+x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{x}{x+2} \, dx}}{(y_1)^2} \, dx \\ &= y_1 \int \frac{e^{-x+2\ln(x+2)}}{(y_1)^2} \, dx \\ &= y_1 \left(\frac{x\, \mathrm{e}^{-x+2\ln(x+2)} \mathrm{e}^{2x}}{(4+x)\,(x+2)^2}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\mathrm{e}^{-x}(4+x)\right) + c_2 \left(\mathrm{e}^{-x}(4+x) \left(\frac{x\, \mathrm{e}^{-x+2\ln(x+2)} \mathrm{e}^{2x}}{(4+x)\,(x+2)^2}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$(x+2)\left(\frac{d^2}{dx^2}y(x)\right)+x\left(\frac{d}{dx}y(x)\right)-y(x)=0$

- Highest derivative means the order of the ODE is 2

$\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

$\frac{d^2}{dx^2}y(x)=\frac{y(x)}{x+2}-\frac{\left(\frac{d}{dx}y(x)\right)x}{x+2}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

$\frac{d^2}{dx^2}y(x)+\frac{\left(\frac{d}{dx}y(x)\right)x}{x+2}-\frac{y(x)}{x+2}=0$

☐ Check to see if $x_0=-2$ is a regular singular point

- ◦ Define functions

  $\left[P_2(x)=\frac{x}{x+2}, P_3(x)=-\frac{1}{x+2}\right]$

- ◦ $(x+2)\cdot P_2(x)$ is analytic at $x=-2$

  $\left((x+2)\cdot P_2(x)\right)\bigg|_{x=-2}=-2$

- ◦ $(x+2)^2\cdot P_3(x)$ is analytic at $x=-2$

  $\left((x+2)^2\cdot P_3(x)\right)\bigg|_{x=-2}=0$

- ◦ $x=-2$is a regular singular point

Check to see if $x_0=-2$ is a regular singular point

$x_0=-2$

- Multiply by denominators

$(x+2)\left(\frac{d^2}{dx^2}y(x)\right)+x\left(\frac{d}{dx}y(x)\right)-y(x)=0$

- Change variables using $x=u-2$ so that the regular singular point is at $u=0$

$u\left(\frac{d^2}{du^2}y(u)\right)+(u-2)\left(\frac{d}{du}y(u)\right)-y(u)=0$

- Assume series solution for $y(u)$

$y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

☐ Rewrite ODE with series expansions

- ◦ Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$

  $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,u^{k+r-1+m}$

- ◦ Shift index using $k->k+1-m$

  $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,u^{k+r}$

- ◦ Convert $u\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion

  $u\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,u^{k+r-1}$

- ◦ Shift index using $k->k+1$

  $u\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=-1}^{\infty}a_{k+1}(k+1+r)\,(k+r)\,u^{k+r}$

Rewrite ODE with series expansions

$a_0r(-3+r)\,u^{-1+r}+\left(\sum_{k=0}^{\infty}\left(a_{k+1}(k+1+r)\,(k-2+r)+a_k(k+r-1)\right)u^{k+r}\right)=0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$r(-3+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{0, 3\}$
- Each term in the series must be 0, giving the recursion relation

  $a_{k+1}(k+1+r)(k-2+r) + a_k(k+r-1) = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+1} = -\frac{a_k(k+r-1)}{(k+1+r)(k-2+r)}$
- Recursion relation for $r = 0$; series terminates at $k = 1$

  $a_{k+1} = -\frac{a_k(k-1)}{(k+1)(k-2)}$
- Apply recursion relation for $k = 0$

  $a_1 = -\frac{a_0}{2}$
- Terminating series solution of the ODE for $r = 0$. Use reduction of order to find the second linea

  $y(u) = a_0 \cdot \left(1 - \frac{u}{2}\right)$
- Revert the change of variables $u = x + 2$

  $\left[y(x) = -\frac{a_0 x}{2}\right]$
- Recursion relation for $r = 3$

  $a_{k+1} = -\frac{a_k(k+2)}{(k+4)(k+1)}$
- Solution for $r = 3$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+3}, a_{k+1} = -\frac{a_k(k+2)}{(k+4)(k+1)}\right]$
- Revert the change of variables $u = x + 2$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k (x+2)^{k+3}, a_{k+1} = -\frac{a_k(k+2)}{(k+4)(k+1)}\right]$
- Combine solutions and rename parameters

  $\left[y(x) = -\frac{a_0 x}{2} + \left(\sum_{k=0}^{\infty} b_k (x+2)^{k+3}\right), b_{k+1} = -\frac{b_k(k+2)}{(4+k)(k+1)}\right]$

2.1.315 Problem 320

Internal problem ID [9487]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 320
Date solved : `Monday, January 27, 2025 at 06:03:21 PM`
CAS classification : `[[_Emden, _Fowler]]`

Solve

$$\left(x^2+1\right) y''-6y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.217 (sec)

Writing the ode as

$$\left(x^2+1\right) y''-6y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2+1 \\ B &= 0 \\ C &= -6 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r=\frac{6}{x^2+1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 6 \\ t &= x^2+1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{6}{x^2+1}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\,e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.595: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = x^2 + 1$. There is a pole at $x = i$ of order 1. There is a pole at $x = -i$ of order 1. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 1. For the pole at $x = i$ of order 1 then

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= 1 \\ \alpha_c^- &= 1 \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{6}{x^2 + 1}$$

Since the $\gcd(s,t) = 1$. This gives $b = 6$. Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^+ &= \frac{1}{2} + \sqrt{1 + 4b} = 3 \\ \alpha_\infty^- &= \frac{1}{2} - \sqrt{1 + 4b} = -2 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{6}{x^2 + 1}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
i	1	0	0	1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	3	-2

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = 3$ then

$$\begin{aligned} d &= \alpha_\infty^+ - \left(\alpha_{c_1}^-\right) \\ &= 3 - (1) \\ &= 2 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + (+)[\sqrt{r}]_\infty \\ &= \frac{1}{x-i} + (0) \\ &= \frac{1}{x-i} \\ &= \frac{1}{x-i} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 2$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x^2 + a_1 x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(2) + 2\left(\frac{1}{x-i}\right)(2x + a_1) + \left(\left(-\frac{1}{(x-i)^2}\right) + \left(\frac{1}{x-i}\right)^2 - \left(\frac{6}{x^2+1}\right)\right) = 0$$

$$2 + \frac{-4x - 2a_1}{-x+i} + \frac{-6x^2 - 6a_1 x - 6a_0}{x^2+1} = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 0, a_1 = i\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^2 + ix$$

Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \left(x^2 + ix\right) \mathrm{e}^{\int \frac{1}{x-i} dx} \\
&= \left(x^2 + ix\right) \mathrm{e}^{\frac{\ln\left(x^2+1\right)}{2} + i \arctan(x)} \\
&= x(x+i)\,(ix+1)
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx}
$$

Since $B = 0$ then the above reduces to

$$
\begin{aligned}
y_1 &= z_1 \\
&= x(x+i)\,(ix+1)
\end{aligned}
$$

Which simplifies to

$$
y_1 = i x^3 + ix
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx
$$

Since $B = 0$ then the above becomes

$$
\begin{aligned}
y_2 &= y_1 \int \frac{1}{y_1^2} \, dx \\
&= i x^3 + ix \int \frac{1}{\left(i x^3 + ix\right)^2} \, dx \\
&= i x^3 + ix \left(\frac{1}{x} + \frac{x}{2x^2+2} + \frac{3 \arctan\left(x\right)}{2}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(i x^3 + ix\right) + c_2 \left(i x^3 + ix \left(\frac{1}{x} + \frac{x}{2x^2+2} + \frac{3 \arctan\left(x\right)}{2}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

2.1.316 Problem 321

Internal problem ID [9488]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 321
Date solved : `Monday, January 27, 2025 at 06:03:22 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$\left(x^2+2\right) y''+3 x y'-y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.424 (sec)

Writing the ode as

$$\left(x^2+2\right) y''+3 x y'-y=0 \tag{1}$$
$$A y''+B y'+C y=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A&=x^2+2\\ B&=3 x\\ C&=-1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=y e^{\int \frac{B}{2 A}\, d x}$$

Then (2) becomes

$$z''(x)=r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r&=\frac{s}{t} \\ &=\frac{2 A B'-2 B A'+B^2-4 A C}{4 A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{7 x^2+20}{4\left(x^2+2\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s&=7 x^2+20\\ t&=4\left(x^2+2\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{7 x^2+20}{4\left(x^2+2\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.596: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^2+2)^2$. There is a pole at $x = i\sqrt{2}$ of order 2. There is a pole at $x = -i\sqrt{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Unable to find solution using case one

Attempting to find a solution using case $n = 2$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{3}{16\left(x - i\sqrt{2}\right)^2} - \frac{3}{16\left(x + i\sqrt{2}\right)^2} - \frac{17i\sqrt{2}}{32\left(x - i\sqrt{2}\right)} + \frac{17i\sqrt{2}}{32\left(x + i\sqrt{2}\right)}$$

For the pole at $x = i\sqrt{2}$ let b be the coefficient of $\frac{1}{\left(x - i\sqrt{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} E_c &= \{2, 2 + 2\sqrt{1+4b}, 2 - 2\sqrt{1+4b}\} \\ &= \{1, 2, 3\} \end{aligned}$$

For the pole at $x = -i\sqrt{2}$ let b be the coefficient of $\frac{1}{\left(x + i\sqrt{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} E_c &= \{2, 2 + 2\sqrt{1+4b}, 2 - 2\sqrt{1+4b}\} \\ &= \{1, 2, 3\} \end{aligned}$$

Since the order of r at ∞ is 2 then let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{7x^2 + 20}{4\left(x^2+2\right)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{7}{4}$. Hence

$$\begin{aligned} E_\infty &= \{2, 2+2\sqrt{1+4b}, 2-2\sqrt{1+4b}\} \\ &= \{2\} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ for case 2 of Kovacic algorithm.

pole c location	pole order	E_c
$i\sqrt{2}$	2	$\{1,2,3\}$
$-i\sqrt{2}$	2	$\{1,2,3\}$

Order of r at ∞	E_∞
2	$\{2\}$

Using the family $\{e_1, e_2, \dots, e_\infty\}$ given by

$$e_1 = 1,\ e_2 = 1,\ e_\infty = 2$$

Gives a non negative integer d (the degree of the polynomial $p(x)$), which is generated using

$$\begin{aligned} d &= \frac{1}{2}\left(e_\infty - \sum_{c\in\Gamma} e_c\right) \\ &= \frac{1}{2}(2-(1+(1))) \\ &= 0 \end{aligned}$$

We now form the following rational function

$$\begin{aligned} \theta &= \frac{1}{2}\sum_{c\in\Gamma}\frac{e_c}{x-c} \\ &= \frac{1}{2}\left(\frac{1}{\left(x-(i\sqrt{2})\right)} + \frac{1}{\left(x-(-i\sqrt{2})\right)}\right) \\ &= \frac{1}{2x-2i\sqrt{2}} + \frac{1}{2x+2i\sqrt{2}} \end{aligned}$$

Now we search for a monic polynomial $p(x)$ of degree $d = 0$ such that

$$p''' + 3\theta p'' + \left(3\theta^2 + 3\theta' - 4r\right)p' + \left(\theta'' + 3\theta\theta' + \theta^3 - 4r\theta - 2r'\right)p = 0 \tag{1A}$$

Since $d = 0$, then letting

$$p = 1 \tag{2A}$$

Substituting p and θ into Eq. (1A) gives

$$0 = 0$$

And solving for p gives

$$p = 1$$

Now that $p(x)$ is found let

$$\begin{aligned}\phi &= \theta + \frac{p'}{p}\\ &= \frac{1}{2x-2i\sqrt{2}} + \frac{1}{2x+2i\sqrt{2}}\end{aligned}$$

Let ω be the solution of

$$\omega^2 - \phi\omega + \left(\frac{1}{2}\phi' + \frac{1}{2}\phi^2 - r\right) = 0$$

Substituting the values for ϕ and r into the above equation gives

$$w^2 - \left(\frac{1}{2x-2i\sqrt{2}} + \frac{1}{2x+2i\sqrt{2}}\right)w + \frac{7x^2+16}{4\left(\sqrt{2}+ix\right)^2\left(x+i\sqrt{2}\right)^2} = 0$$

Solving for ω gives

$$\omega = \frac{x+2\sqrt{2x^2+4}}{2x^2+4}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}z_1(x) &= e^{\int \omega\, dx}\\ &= \mathrm{e}^{\int \frac{x+2\sqrt{2x^2+4}}{2x^2+4}dx}\\ &= \left(x^2+2\right)^{1/4} \mathrm{e}^{\sqrt{2}\, \operatorname{arcsinh}\left(\frac{\sqrt{2}\, x}{2}\right)}\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx}\\ &= z_1 e^{-\int \frac{1}{2}\frac{3x}{x^2+2}\, dx}\\ &= z_1 e^{-\frac{3\ln\left(x^2+2\right)}{4}}\\ &= z_1\left(\frac{1}{\left(x^2+2\right)^{3/4}}\right)\end{aligned}$$

Which simplifies to

$$y_1 = \frac{\mathrm{e}^{\sqrt{2}\, \operatorname{arcsinh}\left(\frac{\sqrt{2}\, x}{2}\right)}}{\sqrt{x^2+2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}y_2 &= y_1 \int \frac{e^{\int -\frac{3x}{x^2+2}\, dx}}{\left(y_1\right)^2}\, dx\\ &= y_1 \int \frac{e^{-\frac{3\ln\left(x^2+2\right)}{2}}}{\left(y_1\right)^2}\, dx\\ &= y_1\left(\int \frac{\mathrm{e}^{-2\sqrt{2}\, \operatorname{arcsinh}\left(\frac{\sqrt{2}\, x}{2}\right)}}{\sqrt{x^2+2}} dx\right)\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{\mathrm{e}^{\sqrt{2}\,\mathrm{arcsinh}\left(\frac{\sqrt{2}\,x}{2}\right)}}{\sqrt{x^2+2}} \right) + c_2 \left(\frac{\mathrm{e}^{\sqrt{2}\,\mathrm{arcsinh}\left(\frac{\sqrt{2}\,x}{2}\right)}}{\sqrt{x^2+2}} \left(\int \frac{\mathrm{e}^{-2\sqrt{2}\,\mathrm{arcsinh}\left(\frac{\sqrt{2}\,x}{2}\right)}}{\sqrt{x^2+2}} dx \right) \right)
\end{aligned}
$$

2.1.317 Problem 322

Internal problem ID [9489]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 322
Date solved : `Monday, January 27, 2025 at 06:03:23 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$(x-1)\,y''-xy'+y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.224 (sec)

Writing the ode as

$$(x-1)\,y''-xy'+y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x-1 \\ B &= -x \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{x^2-4x+6}{4\,(x-1)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2-4x+6 \\ t &= 4(x-1)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{x^2-4x+6}{4\,(x-1)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.597: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x-1)^2$. There is a pole at $x = 1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} + \frac{3}{4\,(x-1)^2} - \frac{1}{2\,(x-1)}$$

For the pole at $x = 1$ let b be the coefficient of $\frac{1}{(x-1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} - \frac{1}{2x} + \frac{1}{x^3} + \frac{11}{4x^4} + \frac{21}{4x^5} + \frac{15}{2x^6} + \frac{6}{x^7} - \frac{117}{16x^8} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 - 4x + 6}{4x^2 - 8x + 4} \\ &= Q + \frac{R}{4x^2 - 8x + 4} \\ &= \left(\frac{1}{4}\right) + \left(\frac{-2x + 5}{4x^2 - 8x + 4}\right) \\ &= \frac{1}{4} + \frac{-2x + 5}{4x^2 - 8x + 4} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is -2. Dividing this by leading coefficient in t which is 4 gives $-\frac{1}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{1}{2}\right) - (0) \\ &= -\frac{1}{2} \end{aligned}$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \frac{1}{2} \\
\alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &&= -\frac{1}{2} \\
\alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &&= \frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{x^2 - 4x + 6}{4(x-1)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
1	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	$-\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = -\frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^+ - (\alpha_{c_1}^-) \\
&= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

Substituting the above values in the above results in

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (+)[\sqrt{r}]_\infty \\
&= -\frac{1}{2(x-1)} + \left(\frac{1}{2}\right) \\
&= -\frac{1}{2(x-1)} + \frac{1}{2} \\
&= \frac{x-2}{2x-2}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(0)+2\left(-\frac{1}{2(x-1)}+\frac{1}{2}\right)(0)+\left(\left(\frac{1}{2(x-1)^2}\right)+\left(-\frac{1}{2(x-1)}+\frac{1}{2}\right)^2-\left(\frac{x^2-4x+6}{4(x-1)^2}\right)\right)=0
$$

$$
0=0
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z''=rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega\,dx} \\
&= \mathrm{e}^{\int \left(-\frac{1}{2(x-1)}+\frac{1}{2}\right)dx} \\
&= \frac{\mathrm{e}^{\frac{x}{2}}}{\sqrt{x-1}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-x}{x-1}\,dx} \\
&= z_1 e^{\frac{x}{2}+\frac{\ln(x-1)}{2}} \\
&= z_1\left(\sqrt{x-1}\,\mathrm{e}^{\frac{x}{2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1=\mathrm{e}^x
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2=y_1\int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1\int \frac{e^{\int -\frac{-x}{x-1}\,dx}}{(y_1)^2}\,dx \\
&= y_1\int \frac{e^{x+\ln(x-1)}}{(y_1)^2}\,dx \\
&= y_1\left(-\frac{x\,\mathrm{e}^{x+\ln(x-1)}\mathrm{e}^{-2x}}{x-1}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1y_1+c_2y_2 \\
&= c_1(\mathrm{e}^x)+c_2\left(\mathrm{e}^x\left(-\frac{x\,\mathrm{e}^{x+\ln(x-1)}\mathrm{e}^{-2x}}{x-1}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$(x-1)\left(\frac{d^2}{dx^2}y(x)\right)-x\left(\frac{d}{dx}y(x)\right)+y(x)=0$

- Highest derivative means the order of the ODE is 2

$\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

$\frac{d^2}{dx^2}y(x)=-\frac{y(x)}{x-1}+\frac{\left(\frac{d}{dx}y(x)\right)x}{x-1}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

$\frac{d^2}{dx^2}y(x)-\frac{\left(\frac{d}{dx}y(x)\right)x}{x-1}+\frac{y(x)}{x-1}=0$

□ Check to see if $x_0=1$ is a regular singular point

- ◦ Define functions

$\left[P_2(x)=-\frac{x}{x-1}, P_3(x)=\frac{1}{x-1}\right]$

- ◦ $(x-1)\cdot P_2(x)$ is analytic at $x=1$

$\left((x-1)\cdot P_2(x)\right)\bigg|_{x=1}=-1$

- ◦ $(x-1)^2\cdot P_3(x)$ is analytic at $x=1$

$\left((x-1)^2\cdot P_3(x)\right)\bigg|_{x=1}=0$

- ◦ $x=1$is a regular singular point

Check to see if $x_0=1$ is a regular singular point

$x_0=1$

- Multiply by denominators

$(x-1)\left(\frac{d^2}{dx^2}y(x)\right)-x\left(\frac{d}{dx}y(x)\right)+y(x)=0$

- Change variables using $x=u+1$ so that the regular singular point is at $u=0$

$u\left(\frac{d^2}{du^2}y(u)\right)+(-u-1)\left(\frac{d}{du}y(u)\right)+y(u)=0$

- Assume series solution for $y(u)$

$y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

□ Rewrite ODE with series expansions

- ◦ Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$

$u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,u^{k+r-1+m}$

- ◦ Shift index using $k->k+1-m$

$u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,u^{k+r}$

- ◦ Convert $u\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion

$u\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,u^{k+r-1}$

- ◦ Shift index using $k->k+1$

$u\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=-1}^{\infty}a_{k+1}(k+1+r)\,(k+r)\,u^{k+r}$

Rewrite ODE with series expansions

$a_0r(-2+r)\,u^{-1+r}+\left(\sum_{k=0}^{\infty}\left(a_{k+1}(k+1+r)\,(k+r-1)-a_k(k+r-1)\right)u^{k+r}\right)=0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$r(-2+r)=0$

- Values of r that satisfy the indicial equation
  $r \in \{0,2\}$
- Each term in the series must be 0, giving the recursion relation
  $(k+r-1)\,(a_{k+1}(k+1+r)-a_k)=0$
- Recursion relation that defines series solution to ODE
  $a_{k+1}=\frac{a_k}{k+1+r}$
- Recursion relation for $r=0$
  $a_{k+1}=\frac{a_k}{k+1}$
- Solution for $r=0$
  $\left[y(u)=\sum_{k=0}^{\infty} a_k u^k, a_{k+1}=\frac{a_k}{k+1}\right]$
- Revert the change of variables $u=x-1$
  $\left[y(x)=\sum_{k=0}^{\infty} a_k(x-1)^k, a_{k+1}=\frac{a_k}{k+1}\right]$
- Recursion relation for $r=2$
  $a_{k+1}=\frac{a_k}{k+3}$
- Solution for $r=2$
  $\left[y(u)=\sum_{k=0}^{\infty} a_k u^{k+2}, a_{k+1}=\frac{a_k}{k+3}\right]$
- Revert the change of variables $u=x-1$
  $\left[y(x)=\sum_{k=0}^{\infty} a_k(x-1)^{k+2}, a_{k+1}=\frac{a_k}{k+3}\right]$
- Combine solutions and rename parameters
  $\left[y(x)=\left(\sum_{k=0}^{\infty} a_k(x-1)^k\right)+\left(\sum_{k=0}^{\infty} b_k(x-1)^{k+2}\right), a_{k+1}=\frac{a_k}{k+1}, b_{k+1}=\frac{b_k}{k+3}\right]$

2.1.318 Problem 325

Internal problem ID [9490]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 325
Date solved : `Monday, January 27, 2025 at 06:03:24 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' + \left(\frac{5}{3}x + x^2\right)y' - \frac{y}{3} = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.412 (sec)

Writing the ode as

$$x^2y'' + \left(\frac{5}{3}x + x^2\right)y' - \frac{y}{3} = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= \frac{5}{3}x + x^2 \\ C &= -\frac{1}{3} \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{9x^2 + 30x + 7}{36x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 9x^2 + 30x + 7 \\ t &= 36x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{9x^2 + 30x + 7}{36x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.599: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 36x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} + \frac{7}{36x^2} + \frac{5}{6x}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{7}{36}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{7}{6} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{1}{6} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} + \frac{5}{6x} - \frac{1}{2x^2} + \frac{5}{6x^3} - \frac{59}{36x^4} + \frac{385}{108x^5} - \frac{2681}{324x^6} + \frac{19525}{972x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{9x^2 + 30x + 7}{36x^2} \\ &= Q + \frac{R}{36x^2} \\ &= \left(\frac{1}{4}\right) + \left(\frac{30x + 7}{36x^2}\right) \\ &= \frac{1}{4} + \frac{30x + 7}{36x^2} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is 30. Dividing this by leading coefficient in t which is 36 gives $\frac{5}{6}$. Now b can be found.

$$\begin{aligned} b &= \left(\frac{5}{6}\right) - (0) \\ &= \frac{5}{6} \end{aligned}$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \frac{1}{2} \\
\alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{\frac{5}{6}}{\frac{1}{2}} - 0\right) &= \frac{5}{6} \\
\alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{\frac{5}{6}}{\frac{1}{2}} - 0\right) &= -\frac{5}{6}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{9x^2 + 30x + 7}{36x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{7}{6}$	$-\frac{1}{6}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	$\frac{5}{6}$	$-\frac{5}{6}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{5}{6}$ then

$$
\begin{aligned}
d &= \alpha_\infty^+ - (\alpha_{c_1}^-) \\
&= \frac{5}{6} - \left(-\frac{1}{6}\right) \\
&= 1
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

Substituting the above values in the above results in

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x - c_1} \right) + (+)[\sqrt{r}]_\infty \\
&= -\frac{1}{6x} + \left(\frac{1}{2}\right) \\
&= -\frac{1}{6x} + \frac{1}{2} \\
&= -\frac{1}{6x} + \frac{1}{2}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = x + a_0 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(-\frac{1}{6x}+\frac{1}{2}\right)(1)+\left(\left(\frac{1}{6x^2}\right)+\left(-\frac{1}{6x}+\frac{1}{2}\right)^2-\left(\frac{9x^2+30x+7}{36x^2}\right)\right)=0$$
$$\frac{-1-3a_0}{3x}=0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\left\{a_0=-\frac{1}{3}\right\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x)=x-\frac{1}{3}$$

Therefore the first solution to the ode $z''=rz$ is

$$\begin{aligned}
z_1(x)&=pe^{\int \omega\,dx}\\
&=\left(x-\frac{1}{3}\right)e^{\int\left(-\frac{1}{6x}+\frac{1}{2}\right)dx}\\
&=\left(x-\frac{1}{3}\right)e^{\frac{x}{2}-\frac{\ln(x)}{6}}\\
&=\frac{(-1+3x)\,e^{\frac{x}{2}}}{3x^{1/6}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1&=z_1e^{\int-\frac{1}{2}\frac{B}{A}\,dx}\\
&=z_1e^{-\int\frac{1}{2}\frac{\frac{5}{3}x+x^2}{x^2}\,dx}\\
&=z_1e^{-\frac{x}{2}-\frac{5\ln(x)}{6}}\\
&=z_1\left(\frac{e^{-\frac{x}{2}}}{x^{5/6}}\right)
\end{aligned}$$

Which simplifies to

$$y_1=\frac{-1+3x}{3x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2=y_1\int\frac{e^{\int-\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2&=y_1\int\frac{e^{\int-\frac{\frac{5}{3}x+x^2}{x^2}\,dx}}{(y_1)^2}\,dx\\
&=y_1\int\frac{e^{-x-\frac{5\ln(x)}{3}}}{(y_1)^2}\,dx\\
&=y_1\left(\int\frac{9\,e^{-x-\frac{5\ln(x)}{3}}x^2}{(-1+3x)^2}dx\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y&=c_1y_1+c_2y_2\\
&=c_1\left(\frac{-1+3x}{3x}\right)+c_2\left(\frac{-1+3x}{3x}\left(\int\frac{9\,e^{-x-\frac{5\ln(x)}{3}}x^2}{(-1+3x)^2}dx\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2\left(\frac{d^2}{dx^2}y(x)\right)+\left(\frac{5}{3}x+x^2\right)\left(\frac{d}{dx}y(x)\right)-\frac{y(x)}{3}=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x)=\frac{y(x)}{3x^2}-\frac{(5+3x)\left(\frac{d}{dx}y(x)\right)}{3x}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x)+\frac{(5+3x)\left(\frac{d}{dx}y(x)\right)}{3x}-\frac{y(x)}{3x^2}=0$

□ Check to see if $x_0=0$ is a regular singular point

  ◦ Define functions

    $\left[P_2(x)=\frac{5+3x}{3x},P_3(x)=-\frac{1}{3x^2}\right]$

  ◦ $x\cdot P_2(x)$ is analytic at $x=0$

    $\left(x\cdot P_2(x)\right)\bigg|_{x=0}=\frac{5}{3}$

  ◦ $x^2\cdot P_3(x)$ is analytic at $x=0$

    $\left(x^2\cdot P_3(x)\right)\bigg|_{x=0}=-\frac{1}{3}$

  ◦ $x=0$is a regular singular point

  Check to see if $x_0=0$ is a regular singular point

  $x_0=0$

- Multiply by denominators

  $3x^2\left(\frac{d^2}{dx^2}y(x)\right)+x(5+3x)\left(\frac{d}{dx}y(x)\right)-y(x)=0$

- Assume series solution for $y(x)$

  $y(x)=\sum_{k=0}^{\infty}a_kx^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $x^m\cdot\left(\frac{d}{dx}y(x)\right)$ to series expansion for $m=1..2$

    $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,x^{k+r-1+m}$

  ◦ Shift index using $k->k+1-m$

    $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,x^{k+r}$

  ◦ Convert $x^2\cdot\left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

    $x^2\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(1+r)\,(-1+3r)\,x^r+\left(\sum_{k=1}^{\infty}\left(a_k(k+r+1)\,(3k+3r-1)+3a_{k-1}(k+r-1)\right)x^{k+r}\right)=0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(1+r)\,(-1+3r)=0$

- Values of r that satisfy the indicial equation

  $r\in\left\{-1,\frac{1}{3}\right\}$

- Each term in the series must be 0, giving the recursion relation

  $3(k+r+1)\left(k-\frac{1}{3}+r\right)a_k+3a_{k-1}(k+r-1)=0$

- Shift index using $k->k+1$

$3(k+2+r)\left(k+\frac{2}{3}+r\right)a_{k+1}+3a_k(k+r)=0$

- Recursion relation that defines series solution to ODE
  $a_{k+1}=-\frac{3a_k(k+r)}{(k+2+r)(3k+2+3r)}$
- Recursion relation for $r=-1$; series terminates at $k=1$
  $a_{k+1}=-\frac{3a_k(k-1)}{(k+1)(3k-1)}$
- Apply recursion relation for $k=0$
  $a_1=-3a_0$
- Terminating series solution of the ODE for $r=-1$. Use reduction of order to find the second lin
  $y(x)=a_0\cdot(1-3x)$
- Recursion relation for $r=\frac{1}{3}$
  $a_{k+1}=-\frac{3a_k\left(k+\frac{1}{3}\right)}{\left(k+\frac{7}{3}\right)(3k+3)}$
- Solution for $r=\frac{1}{3}$
  $\left[y(x)=\sum_{k=0}^{\infty}a_k x^{k+\frac{1}{3}}, a_{k+1}=-\frac{3a_k\left(k+\frac{1}{3}\right)}{\left(k+\frac{7}{3}\right)(3k+3)}\right]$
- Combine solutions and rename parameters
  $\left[y(x)=a_0\cdot(1-3x)+\left(\sum_{k=0}^{\infty}b_k x^{k+\frac{1}{3}}\right), b_{k+1}=-\frac{3b_k\left(k+\frac{1}{3}\right)}{\left(k+\frac{7}{3}\right)(3k+3)}\right]$

Solve

$$2xy'' - y' + 2y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.201 (sec)

Writing the ode as

$$2xy'' - y' + 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2x \\ B &= -1 \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{5 - 16x}{16x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 5 - 16x \\ t &= 16x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{5 - 16x}{16x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\,e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.601: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s)\\
&= 2 - 1\\
&= 1
\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16x^2$. There is a pole at $x = 0$ of order 2. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [2]$$

Attempting to find a solution using case $n = 2$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{5}{16x^2} - \frac{1}{x}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{5}{16}$. Hence

$$\begin{aligned}
E_c &= \{2, 2 + 2\sqrt{1+4b}, 2 - 2\sqrt{1+4b}\}\\
&= \{-1, 2, 5\}
\end{aligned}$$

Since the order of r at ∞ is $1 < 2$ then

$$E_\infty = \{1\}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ for case 2 of Kovacic algorithm.

pole c location	pole order	E_c
0	2	$\{-1,2,5\}$

Order of r at ∞	E_∞
1	$\{1\}$

Using the family $\{e_1, e_2, \ldots, e_\infty\}$ given by

$$e_1 = -1, \; e_\infty = 1$$

Gives a non negative integer d (the degree of the polynomial $p(x)$), which is generated using

$$\begin{aligned} d &= \frac{1}{2}\left(e_\infty - \sum_{c\in\Gamma} e_c\right) \\ &= \frac{1}{2}(1 - (-1)) \\ &= 1 \end{aligned}$$

We now form the following rational function

$$\begin{aligned} \theta &= \frac{1}{2}\sum_{c\in\Gamma} \frac{e_c}{x-c} \\ &= \frac{1}{2}\left(\frac{-1}{(x-(0))}\right) \\ &= -\frac{1}{2x} \end{aligned}$$

Now we search for a monic polynomial $p(x)$ of degree $d = 1$ such that

$$p''' + 3\theta p'' + \left(3\theta^2 + 3\theta' - 4r\right) p' + \left(\theta'' + 3\theta\theta' + \theta^3 - 4r\theta - 2r'\right) p = 0 \tag{1A}$$

Since $d = 1$, then letting

$$p = x + a_0 \tag{2A}$$

Substituting p and θ into Eq. (1A) gives

$$\frac{1 - 4a_0}{x^2} = 0$$

And solving for p gives

$$p = x + \frac{1}{4}$$

Now that $p(x)$ is found let

$$\begin{aligned} \phi &= \theta + \frac{p'}{p} \\ &= \frac{1}{x+\frac{1}{4}} - \frac{1}{2x} \end{aligned}$$

Let ω be the solution of

$$\omega^2 - \phi\omega + \left(\frac{1}{2}\phi' + \frac{1}{2}\phi^2 - r\right) = 0$$

Substituting the values for ϕ and r into the above equation gives

$$w^2 - \left(\frac{1}{x+\frac{1}{4}} - \frac{1}{2x}\right) w + \frac{64x^2 - 12x + 1}{64x^3 + 16x^2} = 0$$

Solving for ω gives

$$\omega = \frac{16x\sqrt{-x} + 4x - 1}{4\,(4x+1)\,x}$$

Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \frac{16x\sqrt{-x}+4x-1}{4(4x+1)x} dx} \\
&= \frac{\left(2\sqrt{-x}-1\right) \mathrm{e}^{2\sqrt{-x}}}{(-x)^{1/4}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-1}{2x} \, dx} \\
&= z_1 e^{\frac{\ln(x)}{4}} \\
&= z_1 \left(x^{1/4}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{x^{1/4}\left(2\sqrt{-x}-1\right) \mathrm{e}^{2\sqrt{-x}}}{(-x)^{1/4}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-1}{2x} \, dx}}{(y_1)^2} \, dx \\
&= y_1 \int \frac{e^{\frac{\ln(x)}{2}}}{(y_1)^2} \, dx \\
&= y_1 \left(\frac{\mathrm{e}^{-4\sqrt{-x}}}{8} + \frac{\mathrm{e}^{-4\sqrt{-x}}}{8\sqrt{-x}-4}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{x^{1/4}\left(2\sqrt{-x}-1\right) \mathrm{e}^{2\sqrt{-x}}}{(-x)^{1/4}}\right) + c_2 \left(\frac{x^{1/4}\left(2\sqrt{-x}-1\right) \mathrm{e}^{2\sqrt{-x}}}{(-x)^{1/4}} \left(\frac{\mathrm{e}^{-4\sqrt{-x}}}{8} + \frac{\mathrm{e}^{-4\sqrt{-x}}}{8\sqrt{-x}-4}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

2.1.320 Problem 327

Internal problem ID [9492]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 327
Date solved : Monday, January 27, 2025 at 06:03:25 PM
CAS classification : [_Laguerre]

Solve

$$2xy'' - (3 + 2x) y' + y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.382 (sec)

Writing the ode as

$$2xy'' + (-3 - 2x) y' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2x \\ B &= -3 - 2x \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{4x^2 + 4x + 21}{16x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 4x^2 + 4x + 21 \\ t &= 16x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{4x^2 + 4x + 21}{16x^2} \right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.603: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} + \frac{1}{4x} + \frac{21}{16x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{21}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{4} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} + \frac{1}{4x} + \frac{5}{4x^2} - \frac{5}{8x^3} - \frac{5}{4x^4} + \frac{35}{16x^5} + \frac{105}{64x^6} - \frac{1005}{128x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $([\sqrt{r}]_\infty)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$([\sqrt{r}]_\infty)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{4x^2 + 4x + 21}{16x^2} \\ &= Q + \frac{R}{16x^2} \\ &= \left(\frac{1}{4}\right) + \left(\frac{4x + 21}{16x^2}\right) \\ &= \frac{1}{4} + \frac{4x + 21}{16x^2} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is 4. Dividing this by leading coefficient in t which is 16 gives $\frac{1}{4}$. Now b can be found.

$$\begin{aligned} b &= \left(\frac{1}{4}\right) - (0) \\ &= \frac{1}{4} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{\frac{1}{4}}{\frac{1}{2}} - 0\right) &&= \frac{1}{4} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{\frac{1}{4}}{\frac{1}{2}} - 0\right) &&= -\frac{1}{4} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{4x^2 + 4x + 21}{16x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{7}{4}$	$-\frac{3}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	$\frac{1}{4}$	$-\frac{1}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{1}{4}$ then

$$\begin{aligned} d &= \alpha_\infty^+ - (\alpha_{c_1}^-) \\ &= \frac{1}{4} - \left(-\frac{3}{4}\right) \\ &= 1 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (+)[\sqrt{r}]_\infty \\ &= -\frac{3}{4x} + \left(\frac{1}{2}\right) \\ &= -\frac{3}{4x} + \frac{1}{2} \\ &= -\frac{3}{4x} + \frac{1}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{3}{4x} + \frac{1}{2}\right)(1) + \left(\left(\frac{3}{4x^2}\right) + \left(-\frac{3}{4x} + \frac{1}{2}\right)^2 - \left(\frac{4x^2+4x+21}{16x^2}\right)\right) = 0$$

$$\frac{-3-2a_0}{2x} = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\left\{a_0 = -\frac{3}{2}\right\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x - \frac{3}{2}$$

Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \left(x - \frac{3}{2}\right) e^{\int \left(-\frac{3}{4x} + \frac{1}{2}\right) dx} \\
&= \left(x - \frac{3}{2}\right) e^{\frac{x}{2} - \frac{3 \ln(x)}{4}} \\
&= \frac{(-3 + 2x) e^{\frac{x}{2}}}{2x^{3/4}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{-3-2x}{2x} \, dx} \\
&= z_1 e^{\frac{x}{2} + \frac{3 \ln(x)}{4}} \\
&= z_1 \left(x^{3/4} e^{\frac{x}{2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{e^{x}(-3 + 2x)}{2}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-3-2x}{2x} \, dx}}{(y_1)^2} \, dx \\
&= y_1 \int \frac{e^{x + \frac{3 \ln(x)}{2}}}{(y_1)^2} \, dx \\
&= y_1 \left(\int \frac{4 e^{x + \frac{3 \ln(x)}{2}} e^{-2x}}{(-3 + 2x)^2} \, dx \right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{e^{x}(-3 + 2x)}{2} \right) + c_2 \left(\frac{e^{x}(-3 + 2x)}{2} \left(\int \frac{4 e^{x + \frac{3 \ln(x)}{2}} e^{-2x}}{(-3 + 2x)^2} \, dx \right) \right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$2\left(\frac{d^2}{dx^2}y(x)\right)x-(2x+3)\left(\frac{d}{dx}y(x)\right)+y(x)=0$

- Highest derivative means the order of the ODE is 2

$\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

$\frac{d^2}{dx^2}y(x)=-\frac{y(x)}{2x}+\frac{(2x+3)\left(\frac{d}{dx}y(x)\right)}{2x}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

$\frac{d^2}{dx^2}y(x)-\frac{(2x+3)\left(\frac{d}{dx}y(x)\right)}{2x}+\frac{y(x)}{2x}=0$

□ Check to see if $x_0=0$ is a regular singular point

  ◦ Define functions

  $\left[P_2(x)=-\frac{2x+3}{2x},P_3(x)=\frac{1}{2x}\right]$

  ◦ $x\cdot P_2(x)$ is analytic at $x=0$

  $\left(x\cdot P_2(x)\right)\Big|_{x=0}=-\frac{3}{2}$

  ◦ $x^2\cdot P_3(x)$ is analytic at $x=0$

  $\left(x^2\cdot P_3(x)\right)\Big|_{x=0}=0$

  ◦ $x=0$is a regular singular point

Check to see if $x_0=0$ is a regular singular point

$x_0=0$

- Multiply by denominators

$2\left(\frac{d^2}{dx^2}y(x)\right)x+(-2x-3)\left(\frac{d}{dx}y(x)\right)+y(x)=0$

- Assume series solution for $y(x)$

$y(x)=\sum_{k=0}^{\infty}a_kx^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $x^m\cdot\left(\frac{d}{dx}y(x)\right)$ to series expansion for $m=0..1$

  $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,x^{k+r-1+m}$

  ◦ Shift index using $k->k+1-m$

  $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,x^{k+r}$

  ◦ Convert $x\cdot\left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

  $x\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,x^{k+r-1}$

  ◦ Shift index using $k->k+1$

  $x\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=-1}^{\infty}a_{k+1}(k+1+r)\,(k+r)\,x^{k+r}$

Rewrite ODE with series expansions

$a_0r(-5+2r)\,x^{-1+r}+\left(\sum_{k=0}^{\infty}\left(a_{k+1}(k+1+r)\,(2k-3+2r)-a_k(2k+2r-1)\right)x^{k+r}\right)=0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$r(-5+2r)=0$

- Values of r that satisfy the indicial equation

$r\in\left\{0,\frac{5}{2}\right\}$

- Each term in the series must be 0, giving the recursion relation
  $2(k+1+r)\left(k+r-\frac{3}{2}\right)a_{k+1}-2\left(k+r-\frac{1}{2}\right)a_k=0$
- Recursion relation that defines series solution to ODE
  $a_{k+1}=\frac{(2k+2r-1)a_k}{(k+1+r)(2k-3+2r)}$
- Recursion relation for $r=0$
  $a_{k+1}=\frac{(2k-1)a_k}{(k+1)(2k-3)}$
- Solution for $r=0$
  $\left[y(x)=\sum_{k=0}^{\infty}a_k x^k, a_{k+1}=\frac{(2k-1)a_k}{(k+1)(2k-3)}\right]$
- Recursion relation for $r=\frac{5}{2}$
  $a_{k+1}=\frac{(2k+4)a_k}{\left(k+\frac{7}{2}\right)(2k+2)}$
- Solution for $r=\frac{5}{2}$
  $\left[y(x)=\sum_{k=0}^{\infty}a_k x^{k+\frac{5}{2}}, a_{k+1}=\frac{(2k+4)a_k}{\left(k+\frac{7}{2}\right)(2k+2)}\right]$
- Combine solutions and rename parameters
  $\left[y(x)=\left(\sum_{k=0}^{\infty}a_k x^k\right)+\left(\sum_{k=0}^{\infty}b_k x^{k+\frac{5}{2}}\right), a_{k+1}=\frac{(2k-1)a_k}{(k+1)(2k-3)}, b_{k+1}=\frac{(2k+4)b_k}{\left(k+\frac{7}{2}\right)(2k+2)}\right]$

2.1.321 Problem 328

Internal problem ID [9493]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 328
Date solved : `Monday, January 27, 2025 at 06:03:26 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$2x^2y''+3xy'+(2x-1)\,y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.207 (sec)

Writing the ode as

$$2x^2y''+3xy'+(2x-1)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A&=2x^2\\ B&=3x\\ C&=2x-1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r&=\frac{s}{t} \\ &=\frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{5-16x}{16x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s&=5-16x\\ t&=16x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{5-16x}{16x^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.605: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 1 \\ &= 1 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16x^2$. There is a pole at $x = 0$ of order 2. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [2]$$

Attempting to find a solution using case $n = 2$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{x} + \frac{5}{16x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{5}{16}$. Hence

$$\begin{aligned} E_c &= \{2, 2 + 2\sqrt{1 + 4b}, 2 - 2\sqrt{1 + 4b}\} \\ &= \{-1, 2, 5\} \end{aligned}$$

Since the order of r at ∞ is $1 < 2$ then

$$E_\infty = \{1\}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ for case 2 of Kovacic algorithm.

pole c location	pole order	E_c
0	2	$\{-1, 2, 5\}$

Order of r at ∞	E_∞
1	$\{1\}$

Using the family $\{e_1, e_2, \dots, e_\infty\}$ given by

$$e_1 = -1,\ e_\infty = 1$$

Gives a non negative integer d (the degree of the polynomial $p(x)$), which is generated using

$$\begin{aligned} d &= \frac{1}{2}\left(e_\infty - \sum_{c\in\Gamma} e_c\right) \\ &= \frac{1}{2}(1-(-1)) \\ &= 1 \end{aligned}$$

We now form the following rational function

$$\begin{aligned} \theta &= \frac{1}{2}\sum_{c\in\Gamma}\frac{e_c}{x-c} \\ &= \frac{1}{2}\left(\frac{-1}{(x-(0))}\right) \\ &= -\frac{1}{2x} \end{aligned}$$

Now we search for a monic polynomial $p(x)$ of degree $d = 1$ such that

$$p''' + 3\theta p'' + \left(3\theta^2 + 3\theta' - 4r\right)p' + \left(\theta'' + 3\theta\theta' + \theta^3 - 4r\theta - 2r'\right)p = 0 \tag{1A}$$

Since $d = 1$, then letting

$$p = x + a_0 \tag{2A}$$

Substituting p and θ into Eq. (1A) gives

$$\frac{1-4a_0}{x^2} = 0$$

And solving for p gives

$$p = x + \frac{1}{4}$$

Now that $p(x)$ is found let

$$\begin{aligned} \phi &= \theta + \frac{p'}{p} \\ &= \frac{1}{x+\frac{1}{4}} - \frac{1}{2x} \end{aligned}$$

Let ω be the solution of

$$\omega^2 - \phi\omega + \left(\frac{1}{2}\phi' + \frac{1}{2}\phi^2 - r\right) = 0$$

Substituting the values for ϕ and r into the above equation gives

$$w^2 - \left(\frac{1}{x+\frac{1}{4}} - \frac{1}{2x}\right)w + \frac{64x^2 - 12x + 1}{64x^3 + 16x^2} = 0$$

Solving for ω gives

$$\omega = \frac{16x\sqrt{-x} + 4x - 1}{4\left(4x+1\right)x}$$

Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \frac{16x\sqrt{-x}+4x-1}{4(4x+1)x} dx} \\
&= \frac{\left(2\sqrt{-x}-1\right) \mathrm{e}^{2\sqrt{-x}}}{\left(-x\right)^{1/4}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{3x}{2x^2} \, dx} \\
&= z_1 e^{-\frac{3\ln(x)}{4}} \\
&= z_1 \left(\frac{1}{x^{3/4}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{\left(2\sqrt{-x}-1\right) \mathrm{e}^{2\sqrt{-x}}}{x^{3/4} \left(-x\right)^{1/4}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{3x}{2x^2} \, dx}}{\left(y_1\right)^2} \, dx \\
&= y_1 \int \frac{e^{-\frac{3\ln(x)}{2}}}{\left(y_1\right)^2} \, dx \\
&= y_1 \left(\frac{\mathrm{e}^{-4\sqrt{-x}}}{8} + \frac{\mathrm{e}^{-4\sqrt{-x}}}{8\sqrt{-x}-4}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{\left(2\sqrt{-x}-1\right) \mathrm{e}^{2\sqrt{-x}}}{x^{3/4} \left(-x\right)^{1/4}}\right) + c_2 \left(\frac{\left(2\sqrt{-x}-1\right) \mathrm{e}^{2\sqrt{-x}}}{x^{3/4} \left(-x\right)^{1/4}} \left(\frac{\mathrm{e}^{-4\sqrt{-x}}}{8} + \frac{\mathrm{e}^{-4\sqrt{-x}}}{8\sqrt{-x}-4}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$2x^2\left(\frac{d^2}{dx^2}y(x)\right)+3x\left(\frac{d}{dx}y(x)\right)+(2x-1)\,y(x)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x)=-\frac{(2x-1)y(x)}{2x^2}-\frac{3\left(\frac{d}{dx}y(x)\right)}{2x}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d^2}{dx^2}y(x)+\frac{3\left(\frac{d}{dx}y(x)\right)}{2x}+\frac{(2x-1)y(x)}{2x^2}=0$

☐ Check to see if $x_0=0$ is a regular singular point

  ◦ Define functions

  $\left[P_2(x)=\frac{3}{2x},P_3(x)=\frac{2x-1}{2x^2}\right]$

  ◦ $x\cdot P_2(x)$ is analytic at $x=0$

  $\left.(x\cdot P_2(x))\right|_{x=0}=\frac{3}{2}$

  ◦ $x^2\cdot P_3(x)$ is analytic at $x=0$

  $\left.(x^2\cdot P_3(x))\right|_{x=0}=-\frac{1}{2}$

  ◦ $x=0$is a regular singular point

  Check to see if $x_0=0$ is a regular singular point

  $x_0=0$

- Multiply by denominators

  $2x^2\left(\frac{d^2}{dx^2}y(x)\right)+3x\left(\frac{d}{dx}y(x)\right)+(2x-1)\,y(x)=0$

- Assume series solution for $y(x)$

  $y(x)=\sum_{k=0}^{\infty}a_kx^{k+r}$

☐ Rewrite ODE with series expansions

  ◦ Convert $x^m\cdot y(x)$ to series expansion for $m=0..1$

  $x^m\cdot y(x)=\sum_{k=0}^{\infty}a_kx^{k+r+m}$

  ◦ Shift index using $k->k-m$

  $x^m\cdot y(x)=\sum_{k=m}^{\infty}a_{k-m}x^{k+r}$

  ◦ Convert $x\cdot\left(\frac{d}{dx}y(x)\right)$ to series expansion

  $x\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,x^{k+r}$

  ◦ Convert $x^2\cdot\left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

  $x^2\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(1+r)\,(-1+2r)\,x^r+\left(\sum_{k=1}^{\infty}\left(a_k(k+r+1)\,(2k+2r-1)+2a_{k-1}\right)x^{k+r}\right)=0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(1+r)\,(-1+2r)=0$

- Values of r that satisfy the indicial equation

  $r\in\left\{-1,\frac{1}{2}\right\}$

- Each term in the series must be 0, giving the recursion relation
  $2(k+r+1)\left(k+r-\frac{1}{2}\right)a_k+2a_{k-1}=0$
- Shift index using $k->k+1$
  $2(k+2+r)\left(k+\frac{1}{2}+r\right)a_{k+1}+2a_k=0$
- Recursion relation that defines series solution to ODE
  $a_{k+1}=-\frac{2a_k}{(k+2+r)(2k+1+2r)}$
- Recursion relation for $r=-1$
  $a_{k+1}=-\frac{2a_k}{(k+1)(2k-1)}$
- Solution for $r=-1$
  $\left[y(x)=\sum_{k=0}^{\infty}a_k x^{k-1}, a_{k+1}=-\frac{2a_k}{(k+1)(2k-1)}\right]$
- Recursion relation for $r=\frac{1}{2}$
  $a_{k+1}=-\frac{2a_k}{\left(k+\frac{5}{2}\right)(2k+2)}$
- Solution for $r=\frac{1}{2}$
  $\left[y(x)=\sum_{k=0}^{\infty}a_k x^{k+\frac{1}{2}}, a_{k+1}=-\frac{2a_k}{\left(k+\frac{5}{2}\right)(2k+2)}\right]$
- Combine solutions and rename parameters
  $\left[y(x)=\left(\sum_{k=0}^{\infty}a_k x^{k-1}\right)+\left(\sum_{k=0}^{\infty}b_k x^{k+\frac{1}{2}}\right), a_{k+1}=-\frac{2a_k}{(k+1)(2k-1)}, b_{k+1}=-\frac{2b_k}{\left(k+\frac{5}{2}\right)(2k+2)}\right]$

2.1.322 Problem 329

Internal problem ID [9494]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 329
Date solved : `Monday, January 27, 2025 at 06:03:26 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$xy'' + 2y' - xy = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.058 (sec)

Writing the ode as

$$xy'' + 2y' - xy = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x \\ B &= 2 \\ C &= -x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.607: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = e^{-x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{2}{x}\, dx} \\ &= z_1 e^{-\ln(x)} \\ &= z_1 \left(\frac{1}{x}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{e^{-x}}{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{2}{x}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{-2\ln(x)}}{(y_1)^2}\,dx \\ &= y_1 \left(\frac{e^{2x}}{2}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\frac{e^{-x}}{x}\right) + c_2 \left(\frac{e^{-x}}{x}\left(\frac{e^{2x}}{2}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

2.1.323 Problem 330

Internal problem ID [9495]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 330
Date solved : `Monday, January 27, 2025 at 06:03:27 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' + xy' + \left(x^2 - \frac{1}{4}\right) y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.141 (sec)

Writing the ode as

$$x^2y'' + xy' + \left(x^2 - \frac{1}{4}\right) y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= x \\ C &= x^2 - \frac{1}{4} \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.609: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{x}{x^2}\, dx} \\ &= z_1 e^{-\frac{\ln(x)}{2}} \\ &= z_1 \left(\frac{1}{\sqrt{x}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{\cos(x)}{\sqrt{x}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{x}{x^2}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-\ln(x)}}{(y_1)^2}\, dx \\ &= y_1(\tan(x)) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\frac{\cos(x)}{\sqrt{x}}\right) + c_2\left(\frac{\cos(x)}{\sqrt{x}}(\tan(x))\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2\left(\frac{d^2}{dx^2}y(x)\right) + x\left(\frac{d}{dx}y(x)\right) + \left(x^2 - \frac{1}{4}\right)y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{(4x^2-1)y(x)}{4x^2} - \frac{\frac{d}{dx}y(x)}{x}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x) + \frac{\frac{d}{dx}y(x)}{x} + \frac{(4x^2-1)y(x)}{4x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

  $\left[P_2(x) = \frac{1}{x}, P_3(x) = \frac{4x^2-1}{4x^2}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

  $\left.(x \cdot P_2(x))\right|_{x=0} = 1$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $\left.(x^2 \cdot P_3(x))\right|_{x=0} = -\frac{1}{4}$

  ◦ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

2.1.324 Problem 331

Internal problem ID [9496]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 331
Date solved : `Monday, January 27, 2025 at 06:03:27 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$xy'' + (x-6)\,y' - 3y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.264 (sec)

Writing the ode as

$$xy'' + (x-6)\,y' - 3y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x \\ B &= x-6 \\ C &= -3 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2+48}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2 + 48 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2+48}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.611: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1,2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} + \frac{12}{x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = 12$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 4 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -3 \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} + \frac{12}{x^2} - \frac{144}{x^4} + \frac{3456}{x^6} - \frac{103680}{x^8} + \frac{3483648}{x^{10}} - \frac{125411328}{x^{12}} + \frac{4729798656}{x^{14}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{2}\end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 + 48}{4x^2} \\ &= Q + \frac{R}{4x^2} \\ &= \left(\frac{1}{4}\right) + \left(\frac{12}{x^2}\right) \\ &= \frac{1}{4} + \frac{12}{x^2} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is 0. Dividing this by leading coefficient in t which is 4 gives 0. Now b can be found.

$$\begin{aligned} b &= (0) - (0) \\ &= 0 \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{0}{\frac{1}{2}} - 0\right) &= 0 \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{0}{\frac{1}{2}} - 0\right) &= 0 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2 + 48}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	4	-3

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	0	0

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 0$ then

$$\begin{aligned} d &= \alpha_\infty^- - (\alpha_{c_1}^-) \\ &= 0 - (-3) \\ &= 3 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + (-)[\sqrt{r}]_\infty \\ &= -\frac{3}{x} + (-)\left(\frac{1}{2}\right) \\ &= -\frac{3}{x} - \frac{1}{2} \\ &= -\frac{6+x}{2x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 3$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = x^3 + a_2x^2 + a_1x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(6x + 2a_2) + 2\left(-\frac{3}{x} - \frac{1}{2}\right)(3x^2 + 2a_2x + a_1) + \left(\left(\frac{3}{x^2}\right) + \left(-\frac{3}{x} - \frac{1}{2}\right)^2 - \left(\frac{x^2+48}{4x^2}\right)\right) = 0$$

$$\frac{(a_2 - 12)\, x^2 + 2(a_1 - 5a_2)\, x + 3a_0 - 6a_1}{x} = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 120, a_1 = 60, a_2 = 12\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^3 + 12x^2 + 60x + 120$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= \left(x^3 + 12x^2 + 60x + 120\right) \mathrm{e}^{\int \left(-\frac{3}{x} - \frac{1}{2}\right) dx} \\ &= \left(x^3 + 12x^2 + 60x + 120\right) \mathrm{e}^{-\frac{x}{2} - 3\ln(x)} \\ &= \frac{\left(x^3 + 12x^2 + 60x + 120\right) \mathrm{e}^{-\frac{x}{2}}}{x^3} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2} \frac{x-6}{x} \, dx} \\ &= z_1 e^{-\frac{x}{2} + 3\ln(x)} \\ &= z_1 \left(x^3 \mathrm{e}^{-\frac{x}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-x} \left(x^3 + 12x^2 + 60x + 120\right)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{x-6}{x} \, dx}}{(y_1)^2} \, dx \\ &= y_1 \int \frac{e^{-x + 6\ln(x)}}{(y_1)^2} \, dx \\ &= y_1 \left(\frac{\left(x^3 - 12x^2 + 60x - 120\right) \mathrm{e}^{-x + 6\ln(x)} \mathrm{e}^{2x}}{\left(x^3 + 12x^2 + 60x + 120\right) x^6} \right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\mathrm{e}^{-x} \left(x^3 + 12x^2 + 60x + 120\right)\right) \\ &\quad + c_2 \left(\mathrm{e}^{-x} \left(x^3 + 12x^2 + 60x + 120\right) \left(\frac{\left(x^3 - 12x^2 + 60x - 120\right) \mathrm{e}^{-x + 6\ln(x)} \mathrm{e}^{2x}}{\left(x^3 + 12x^2 + 60x + 120\right) x^6} \right) \right) \end{aligned}$$

Will add steps showing solving for IC soon.

Problem number : 332
Date solved : `Monday, January 27, 2025 at 06:03:28 PM`
CAS classification : `[[_Emden, _Fowler]]`

Solve

$$x^4y'' + \lambda y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.237 (sec)

Writing the ode as

$$x^4y'' + \lambda y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^4 \\ B &= 0 \\ C &= \lambda \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-\lambda}{x^4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -\lambda \\ t &= x^4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{\lambda}{x^4}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.613: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 0 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = x^4$. There is a pole at $x = 0$ of order 4. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Looking at higher order poles of order $2v \geq 4$ (must be even order for case one).Then for each pole c, $[\sqrt{r}]_c$ is the sum of terms $\frac{1}{(x-c)^i}$ for $2 \leq i \leq v$ in the Laurent series expansion of $\sqrt{r}$ expanded around each pole c. Hence

$$[\sqrt{r}]_c = \sum_{2}^{v} \frac{a_i}{(x-c)^i} \tag{1B}$$

Let a be the coefficient of the term $\frac{1}{(x-c)^v}$ in the above where v is the pole order divided by 2. Let b be the coefficient of $\frac{1}{(x-c)^{v+1}}$ in r minus the coefficient of $\frac{1}{(x-c)^{v+1}}$ in $[\sqrt{r}]_c$. Then

$$\begin{aligned} \alpha_c^+ &= \frac{1}{2}\left(\frac{b}{a} + v\right) \\ \alpha_c^- &= \frac{1}{2}\left(-\frac{b}{a} + v\right) \end{aligned}$$

The partial fraction decomposition of r is

$$r = -\frac{\lambda}{x^4}$$

There is pole in r at $x = 0$ of order 4, hence $v = 2$. Expanding $\sqrt{r}$ as Laurent series about this pole $c = 0$ gives

$$[\sqrt{r}]_c \approx \frac{i\sqrt{\lambda}}{x^2} + \dots \tag{2B}$$

Using eq. (1B), taking the sum up to $v = 2$ the above becomes

$$[\sqrt{r}]_c = \frac{i\sqrt{\lambda}}{x^2} \tag{3B}$$

The above shows that the coefficient of $\frac{1}{(x-0)^2}$ is

$$a = i\sqrt{\lambda}$$

Now we need to find b. let b be the coefficient of the term $\frac{1}{(x-c)^{v+1}}$ in r minus the coefficient of the same term but in the sum $[\sqrt{r}]_c$ found in eq. (3B). Here c is current pole which is $c = 0$. This term becomes $\frac{1}{x^3}$. The coefficient of this term in the sum $[\sqrt{r}]_c$ is seen to be 0 and the coefficient of this term r is found from the partial fraction decomposition from above to be 0. Therefore

$$\begin{aligned} b &= (0) - (0) \\ &= 0 \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_c &= \frac{i\sqrt{\lambda}}{x^2} \\ \alpha_c^+ &= \frac{1}{2}\left(\frac{b}{a} + v\right) &&= \frac{1}{2}\left(\frac{0}{i\sqrt{\lambda}} + 2\right) &&= 1 \\ \alpha_c^- &= \frac{1}{2}\left(-\frac{b}{a} + v\right) &&= \frac{1}{2}\left(-\frac{0}{i\sqrt{\lambda}} + 2\right) &&= 1 \end{aligned}$$

Since the order of r at ∞ is $4 > 2$ then

$$\begin{aligned} [\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^+ &= 0 \\ \alpha_\infty^- &= 1 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = -\frac{\lambda}{x^4}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	4	$\frac{i\sqrt{\lambda}}{x^2}$	1	1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\ &= 1 - (1) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{i\sqrt{\lambda}}{x^2} + \frac{1}{x} + (-)\,(0) \\
&= -\frac{i\sqrt{\lambda}}{x^2} + \frac{1}{x} \\
&= \frac{-i\sqrt{\lambda} + x}{x^2}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{i\sqrt{\lambda}}{x^2} + \frac{1}{x}\right)(0) + \left(\left(\frac{2i\sqrt{\lambda}}{x^3} - \frac{1}{x^2}\right) + \left(-\frac{i\sqrt{\lambda}}{x^2} + \frac{1}{x}\right)^2 - \left(-\frac{\lambda}{x^4}\right)\right) = 0$$

$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx} \\
&= \mathrm{e}^{\int \left(-\frac{i\sqrt{\lambda}}{x^2} + \frac{1}{x}\right) dx} \\
&= x\, \mathrm{e}^{\frac{i\sqrt{\lambda}}{x}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned}
y_1 &= z_1 \\
&= x\, \mathrm{e}^{\frac{i\sqrt{\lambda}}{x}}
\end{aligned}$$

Which simplifies to

$$y_1 = x\, \mathrm{e}^{\frac{i\sqrt{\lambda}}{x}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Since $B = 0$ then the above becomes

$$
\begin{aligned}
y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\
&= x\, \mathrm{e}^{\frac{i\sqrt{\lambda}}{x}} \int \frac{1}{x^2 \mathrm{e}^{\frac{2i\sqrt{\lambda}}{x}}}\, dx \\
&= x\, \mathrm{e}^{\frac{i\sqrt{\lambda}}{x}} \left(-\frac{i\mathrm{e}^{-\frac{2i\sqrt{\lambda}}{x}}}{2\sqrt{\lambda}}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(x\, \mathrm{e}^{\frac{i\sqrt{\lambda}}{x}}\right) + c_2 \left(x\, \mathrm{e}^{\frac{i\sqrt{\lambda}}{x}} \left(-\frac{i\mathrm{e}^{-\frac{2i\sqrt{\lambda}}{x}}}{2\sqrt{\lambda}}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

2.1.326 Problem 333

Internal problem ID [9498]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 333
Date solved : `Monday, January 27, 2025 at 06:03:29 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$4x^2y'' + 4xy' + \left(4x^2 - 25\right) y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.287 (sec)

Writing the ode as

$$4x^2y'' + 4xy' + \left(4x^2 - 25\right) y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4x^2 \\ B &= 4x \\ C &= 4x^2 - 25 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-x^2 + 6}{x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -x^2 + 6 \\ t &= x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{-x^2 + 6}{x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.614: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s)\\
&= 2 - 2\\
&= 0
\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1,2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -1 + \frac{6}{x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = 6$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0\\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 3\\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -2
\end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i\\
&= \sum_{i=0}^{0} a_i x^i
\end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx i - \frac{3i}{x^2} - \frac{9i}{2x^4} - \frac{27i}{2x^6} - \frac{405i}{8x^8} - \frac{1701i}{8x^{10}} - \frac{15309i}{16x^{12}} - \frac{72171i}{16x^{14}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = i$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= i \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = -1$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{-x^2 + 6}{x^2} \\ &= Q + \frac{R}{x^2} \\ &= (-1) + \left(\frac{6}{x^2}\right) \\ &= -1 + \frac{6}{x^2} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is 0. Dividing this by leading coefficient in t which is 1 gives 0. Now b can be found.

$$\begin{aligned} b &= (0) - (0) \\ &= 0 \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= i \\ \alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{0}{i} - 0\right) &&= 0 \\ \alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{0}{i} - 0\right) &&= 0 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{-x^2 + 6}{x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	3	-2

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	i	0	0

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 0$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\ &= 0 - (-2) \\ &= 2 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= -\frac{2}{x} + (-)(i) \\ &= -\frac{2}{x} - i \\ &= -\frac{2}{x} - i \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 2$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x^2 + a_1 x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(2) + 2\left(-\frac{2}{x} - i\right)(2x + a_1) + \left(\left(\frac{2}{x^2}\right) + \left(-\frac{2}{x} - i\right)^2 - \left(\frac{-x^2+6}{x^2}\right) \right) = 0$$

$$\frac{2ixa_1 + 4ia_0 - 6x - 4a_1}{x} = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = -3, a_1 = -3i\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^2 - 3ix - 3$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega\, dx} \\ &= \left(x^2 - 3ix - 3\right) e^{\int \left(-\frac{2}{x} - i\right) dx} \\ &= \left(x^2 - 3ix - 3\right) e^{-2\ln(x) - ix} \\ &= \frac{\left(x^2 - 3ix - 3\right) e^{-ix}}{x^2} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{4x}{4x^2}\,dx} \\
&= z_1 e^{-\frac{\ln(x)}{2}} \\
&= z_1\left(\frac{1}{\sqrt{x}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{(x^2 - 3ix - 3)\,\mathrm{e}^{-ix}}{x^{5/2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{4x}{4x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\ln(x)}}{(y_1)^2}\,dx \\
&= y_1\left(\frac{(ix^2 - 3x - 3i)\,\mathrm{e}^{2ix}}{-2x^2 + 6ix + 6}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{(x^2 - 3ix - 3)\,\mathrm{e}^{-ix}}{x^{5/2}}\right) + c_2\left(\frac{(x^2 - 3ix - 3)\,\mathrm{e}^{-ix}}{x^{5/2}}\left(\frac{(ix^2 - 3x - 3i)\,\mathrm{e}^{2ix}}{-2x^2 + 6ix + 6}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$4x^2\left(\frac{d^2}{dx^2}y(x)\right) + 4x\left(\frac{d}{dx}y(x)\right) + (4x^2 - 25)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{(4x^2-25)y(x)}{4x^2} - \frac{\frac{d}{dx}y(x)}{x}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x) + \frac{\frac{d}{dx}y(x)}{x} + \frac{(4x^2-25)y(x)}{4x^2} = 0$

- ☐ Check to see if $x_0 = 0$ is a regular singular point
  - ○ Define functions

    $\left[P_2(x) = \frac{1}{x}, P_3(x) = \frac{4x^2-25}{4x^2}\right]$

  - ○ $x \cdot P_2(x)$ is analytic at $x = 0$

$$\left(x \cdot P_2(x)\right)\bigg|_{x=0} = 1$$

- $x^2 \cdot P_3(x)$ is analytic at $x = 0$

$$\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = -\frac{25}{4}$$

- $x = 0$is a regular singular point

Check to see if $x_0 = 0$ is a regular singular point

$x_0 = 0$

- Multiply by denominators

$$4x^2\left(\frac{d^2}{dx^2}y(x)\right) + 4x\left(\frac{d}{dx}y(x)\right) + (4x^2 - 25)\, y(x) = 0$$

- Assume series solution for $y(x)$

$$y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$$

☐ Rewrite ODE with series expansions

- Convert $x^m \cdot y(x)$ to series expansion for $m = 0..2$

$$x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$$

- Shift index using $k- >k - m$

$$x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$$

- Convert $x \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion

$$x \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r}$$

- Convert $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

$$x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0(5+2r)\,(-5+2r)\, x^r + a_1(7+2r)\,(-3+2r)\, x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(2k+2r+5)\,(2k+2r-5) + 4a\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$(5+2r)\,(-5+2r) = 0$

- Values of r that satisfy the indicial equation

$r \in \left\{-\frac{5}{2}, \frac{5}{2}\right\}$

- Each term must be 0

$a_1(7+2r)\,(-3+2r) = 0$

- Solve for the dependent coefficient(s)

$a_1 = 0$

- Each term in the series must be 0, giving the recursion relation

$a_k(2k+2r+5)\,(2k+2r-5) + 4a_{k-2} = 0$

- Shift index using $k- >k + 2$

$a_{k+2}(2k+9+2r)\,(2k-1+2r) + 4a_k = 0$

- Recursion relation that defines series solution to ODE

$a_{k+2} = -\frac{4a_k}{(2k+9+2r)(2k-1+2r)}$

- Recursion relation for $r = -\frac{5}{2}$

$a_{k+2} = -\frac{4a_k}{(2k+4)(2k-6)}$

- Solution for $r = -\frac{5}{2}$

$$\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k-\frac{5}{2}}, a_{k+2} = -\frac{4a_k}{(2k+4)(2k-6)}, a_1 = 0\right]$$

- Recursion relation for $r = \frac{5}{2}$

  $a_{k+2} = -\frac{4a_k}{(2k+14)(2k+4)}$
- Solution for $r = \frac{5}{2}$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+\frac{5}{2}}, a_{k+2} = -\frac{4a_k}{(2k+14)(2k+4)}, a_1 = 0\right]$
- Combine solutions and rename parameters

  $\left[y(x) = \left(\sum_{k=0}^{\infty} a_k x^{k-\frac{5}{2}}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{5}{2}}\right), a_{k+2} = -\frac{4a_k}{(2k+4)(2k-6)}, a_1 = 0, b_{k+2} = -\frac{4b_k}{(2k+14)(2k+4)}, b_1 = 0\right]$

CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' + xy' + \left(36x^2 - \frac{1}{4}\right) y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.155 (sec)

Writing the ode as

$$x^2y'' + xy' + \left(36x^2 - \frac{1}{4}\right) y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= x \\ C &= 36x^2 - \frac{1}{4} \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-36}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -36 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -36z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.616: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -36$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(6x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{x}{x^2}\, dx} \\ &= z_1 e^{-\frac{\ln(x)}{2}} \\ &= z_1 \left(\frac{1}{\sqrt{x}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{\cos(6x)}{\sqrt{x}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{x}{x^2}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{-\ln(x)}}{(y_1)^2}\,dx \\ &= y_1 \left(\frac{\tan(6x)}{6}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\frac{\cos(6x)}{\sqrt{x}}\right) + c_2\left(\frac{\cos(6x)}{\sqrt{x}}\left(\frac{\tan(6x)}{6}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2\left(\frac{d^2}{dx^2}y(x)\right) + x\left(\frac{d}{dx}y(x)\right) + \left(36x^2 - \frac{1}{4}\right)y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{(144x^2-1)y(x)}{4x^2} - \frac{\frac{d}{dx}y(x)}{x}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x) + \frac{\frac{d}{dx}y(x)}{x} + \frac{(144x^2-1)y(x)}{4x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

  $\left[P_2(x) = \frac{1}{x}, P_3(x) = \frac{144x^2-1}{4x^2}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

  $\left.(x \cdot P_2(x))\right|_{x=0} = 1$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $\left.(x^2 \cdot P_3(x))\right|_{x=0} = -\frac{1}{4}$

  ◦ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $4x^2\left(\frac{d^2}{dx^2}y(x)\right) + 4x\left(\frac{d}{dx}y(x)\right) + (144x^2 - 1)y(x) = 0$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

- □ Rewrite ODE with series expansions
  - ◦ Convert $x^m \cdot y(x)$ to series expansion for $m = 0..2$

    $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$
  - ◦ Shift index using $k- >k - m$

    $x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$
  - ◦ Convert $x \cdot \left(\frac{d}{dx} y(x)\right)$ to series expansion

    $x \cdot \left(\frac{d}{dx} y(x)\right) = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r}$
  - ◦ Convert $x^2 \cdot \left(\frac{d^2}{dx^2} y(x)\right)$ to series expansion

    $x^2 \cdot \left(\frac{d^2}{dx^2} y(x)\right) = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(1+2r)\,(-1+2r)\, x^r + a_1(3+2r)\,(1+2r)\, x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(2k+2r+1)\,(2k+2r-1) + 144a_{k-2}\right.\right.$
- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(1+2r)\,(-1+2r) = 0$
- Values of r that satisfy the indicial equation

  $r \in \left\{-\frac{1}{2}, \frac{1}{2}\right\}$
- Each term must be 0

  $a_1(3+2r)\,(1+2r) = 0$
- Solve for the dependent coefficient(s)

  $a_1 = 0$
- Each term in the series must be 0, giving the recursion relation

  $a_k(4k^2 + 8kr + 4r^2 - 1) + 144a_{k-2} = 0$
- Shift index using $k- >k + 2$

  $a_{k+2}\left(4(k+2)^2 + 8(k+2)\, r + 4r^2 - 1\right) + 144a_k = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{144a_k}{4k^2+8kr+4r^2+16k+16r+15}$
- Recursion relation for $r = -\frac{1}{2}$

  $a_{k+2} = -\frac{144a_k}{4k^2+12k+8}$
- Solution for $r = -\frac{1}{2}$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k-\frac{1}{2}}, a_{k+2} = -\frac{144a_k}{4k^2+12k+8}, a_1 = 0\right]$
- Recursion relation for $r = \frac{1}{2}$

  $a_{k+2} = -\frac{144a_k}{4k^2+20k+24}$
- Solution for $r = \frac{1}{2}$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}, a_{k+2} = -\frac{144a_k}{4k^2+20k+24}, a_1 = 0\right]$
- Combine solutions and rename parameters

  $\left[y(x) = \left(\sum_{k=0}^{\infty} a_k x^{k-\frac{1}{2}}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{2}}\right), a_{k+2} = -\frac{144a_k}{4k^2+12k+8}, a_1 = 0, b_{k+2} = -\frac{144b_k}{4k^2+20k+24}, b_1 = 0\right]$

2.1.328 Problem 335

Internal problem ID [9500]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 335
Date solved : `Monday, January 27, 2025 at 06:03:30 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' + (x^2-2)\, y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.261 (sec)

Writing the ode as

$$x^2y'' + (x^2-2)\, y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= 0 \\ C &= x^2-2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-x^2+2}{x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -x^2+2 \\ t &= x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{-x^2+2}{x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.618: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -1 + \frac{2}{x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1 \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx i - \frac{i}{x^2} - \frac{i}{2x^4} - \frac{i}{2x^6} - \frac{5i}{8x^8} - \frac{7i}{8x^{10}} - \frac{21i}{16x^{12}} - \frac{33i}{16x^{14}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = i$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= i \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = -1$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{-x^2 + 2}{x^2} \\ &= Q + \frac{R}{x^2} \\ &= (-1) + \left(\frac{2}{x^2}\right) \\ &= -1 + \frac{2}{x^2} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is 0. Dividing this by leading coefficient in t which is 1 gives 0. Now b can be found.

$$\begin{aligned} b &= (0) - (0) \\ &= 0 \end{aligned}$$

Hence
