2.1.1 Problem 1

Internal problem ID [9173]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 1
Date solved : `Monday, January 27, 2025 at 05:51:43 PM`
CAS classification : `[_Gegenbauer]`

Solve

$$\left(x^2-1\right) y''-2xy'+2y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.194 (sec)

Writing the ode as

$$\left(x^2-1\right) y''-2xy'+2y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2-1 \\ B &= -2x \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r=\frac{3}{\left(x^2-1\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 3 \\ t &= \left(x^2-1\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{3}{\left(x^2-1\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.1: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 0 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (x^2 - 1)^2$. There is a pole at $x = 1$ of order 2. There is a pole at $x = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{3}{4(x+1)} - \frac{3}{4(x-1)} + \frac{3}{4(x+1)^2} + \frac{3}{4(x-1)^2}$$

For the pole at $x = 1$ let b be the coefficient of $\frac{1}{(x-1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

For the pole at $x = -1$ let b be the coefficient of $\frac{1}{(x+1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $4 > 2$ then

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= 0 \\
\alpha_\infty^{-} &= 1
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{3}{(x^2-1)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
1	2	0	$\frac{3}{2}$	$-\frac{1}{2}$
-1	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = 1$ then

$$\begin{aligned}
d &= \alpha_\infty^{-} - \left(\alpha_{c_1}^{-} + \alpha_{c_2}^{+}\right) \\
&= 1 - (1) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x-c_1}\right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{+}}{x-c_2}\right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{1}{2\,(x-1)} + \frac{3}{2\,(x+1)} + (-)\,(0) \\
&= -\frac{1}{2\,(x-1)} + \frac{3}{2\,(x+1)} \\
&= \frac{x-2}{x^2-1}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(-\frac{1}{2(x-1)}+\frac{3}{2(x+1)}\right)(0)+\left(\left(\frac{1}{2(x-1)^2}-\frac{3}{2(x+1)^2}\right)+\left(-\frac{1}{2(x-1)}+\frac{3}{2(x+1)}\right)^2-\left(\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z''=rz$ is

$$\begin{aligned}
z_1(x) &= pe^{\int \omega\, dx}\\
&= \mathrm{e}^{\int \left(-\frac{1}{2(x-1)}+\frac{3}{2(x+1)}\right)dx}\\
&= \frac{(x+1)^{3/2}}{\sqrt{x-1}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx}\\
&= z_1 e^{-\int \frac{1}{2}\frac{-2x}{x^2-1}\, dx}\\
&= z_1 e^{\frac{\ln(x-1)}{2}+\frac{\ln(x+1)}{2}}\\
&= z_1\left(\sqrt{x-1}\,\sqrt{x+1}\right)
\end{aligned}$$

Which simplifies to

$$y_1=(x+1)^2$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2=y_1\int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1\int \frac{e^{\int -\frac{-2x}{x^2-1}\, dx}}{(y_1)^2}\, dx\\
&= y_1\int \frac{e^{\ln(x-1)+\ln(x+1)}}{(y_1)^2}\, dx\\
&= y_1\left(-\frac{x\,\mathrm{e}^{\ln(x-1)+\ln(x+1)}}{(x+1)^3\,(x-1)}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1y_1+c_2y_2\\
&= c_1\left((x+1)^2\right)+c_2\left((x+1)^2\left(-\frac{x\,\mathrm{e}^{\ln(x-1)+\ln(x+1)}}{(x+1)^3\,(x-1)}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$(x^2-1)\left(\frac{d^2}{dx^2}y(x)\right)-2x\left(\frac{d}{dx}y(x)\right)+2y(x)=0$

- Highest derivative means the order of the ODE is 2

$\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

$\frac{d^2}{dx^2}y(x)=-\frac{2y(x)}{x^2-1}+\frac{2\left(\frac{d}{dx}y(x)\right)x}{x^2-1}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

$\frac{d^2}{dx^2}y(x)-\frac{2\left(\frac{d}{dx}y(x)\right)x}{x^2-1}+\frac{2y(x)}{x^2-1}=0$

□ Check to see if x_0 is a regular singular point

- ◦ Define functions

$\left[P_2(x)=-\frac{2x}{x^2-1}, P_3(x)=\frac{2}{x^2-1}\right]$

- ◦ $(x+1)\cdot P_2(x)$ is analytic at $x=-1$

$\left((x+1)\cdot P_2(x)\right)\Big|_{x=-1}=-1$

- ◦ $(x+1)^2\cdot P_3(x)$ is analytic at $x=-1$

$\left((x+1)^2\cdot P_3(x)\right)\Big|_{x=-1}=0$

- ◦ $x=-1$is a regular singular point

Check to see if x_0 is a regular singular point

$x_0=-1$

- Multiply by denominators

$(x^2-1)\left(\frac{d^2}{dx^2}y(x)\right)-2x\left(\frac{d}{dx}y(x)\right)+2y(x)=0$

- Change variables using $x=u-1$ so that the regular singular point is at $u=0$

$(u^2-2u)\left(\frac{d^2}{du^2}y(u)\right)+(-2u+2)\left(\frac{d}{du}y(u)\right)+2y(u)=0$

- Assume series solution for $y(u)$

$y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

□ Rewrite ODE with series expansions

- ◦ Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$

$u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,u^{k+r-1+m}$

- ◦ Shift index using $k->k+1-m$

$u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,u^{k+r}$

- ◦ Convert $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m=1..2$

$u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)(k+r-1)\,u^{k+r-2+m}$

- ◦ Shift index using $k->k+2-m$

$u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=-2+m}^{\infty}a_{k+2-m}(k+2-m+r)(k+1-m+r)\,u^{k+r}$

Rewrite ODE with series expansions

$-2a_0r(-2+r)\,u^{-1+r}+\left(\sum_{k=0}^{\infty}\left(-2a_{k+1}(k+1+r)(k+r-1)+a_k(k+r-1)(k+r-2)\right)u^{k+r}\right)=$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$-2r(-2+r)=0$

- Values of r that satisfy the indicial equation
$r \in \{0, 2\}$
- Each term in the series must be 0, giving the recursion relation
$(k+r-1)\left((-2k-2r-2)\,a_{k+1}+a_k(k+r-2)\right)=0$
- Recursion relation that defines series solution to ODE
$a_{k+1}=\frac{a_k(k+r-2)}{2(k+1+r)}$
- Recursion relation for $r=0$; series terminates at $k=2$
$a_{k+1}=\frac{a_k(k-2)}{2(k+1)}$
- Apply recursion relation for $k=0$
$a_1=-a_0$
- Apply recursion relation for $k=1$
$a_2=-\frac{a_1}{4}$
- Express in terms of a_0
$a_2=\frac{a_0}{4}$
- Terminating series solution of the ODE for $r=0$. Use reduction of order to find the second li
$y(u)=a_0\cdot\left(1-u+\frac{1}{4}u^2\right)$
- Revert the change of variables $u=x+1$
$\left[y(x)=\frac{a_0(x-1)^2}{4}\right]$
- Recursion relation for $r=2$
$a_{k+1}=\frac{a_k k}{2(k+3)}$
- Solution for $r=2$
$\left[y(u)=\sum_{k=0}^{\infty} a_k u^{k+2}, a_{k+1}=\frac{a_k k}{2(k+3)}\right]$
- Revert the change of variables $u=x+1$
$\left[y(x)=\sum_{k=0}^{\infty} a_k(x+1)^{k+2}, a_{k+1}=\frac{a_k k}{2(k+3)}\right]$
- Combine solutions and rename parameters
$\left[y(x)=\frac{a_0(x-1)^2}{4}+\left(\sum_{k=0}^{\infty} b_k(x+1)^{k+2}\right), b_{k+1}=\frac{b_k k}{2(k+3)}\right]$

2.1.2 Problem 2

Internal problem ID [9174]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 2
Date solved : `Monday, January 27, 2025 at 05:51:43 PM`
CAS classification : `[_Gegenbauer]`

Solve

$$(x^2-1)\,y''-6xy'+12y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.208 (sec)

Writing the ode as

$$(x^2-1)\,y''-6xy'+12y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2-1\\ B &= -6x \\ C &= 12 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{15}{(x^2-1)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 15\\ t &= (x^2-1)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{15}{(x^2-1)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.3: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 0 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (x^2-1)^2$. There is a pole at $x = 1$ of order 2. There is a pole at $x = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{15}{4(x+1)^2} + \frac{15}{4(x+1)} + \frac{15}{4(x-1)^2} - \frac{15}{4(x-1)}$$

For the pole at $x = 1$ let b be the coefficient of $\frac{1}{(x-1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{15}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{2} \end{aligned}$$

For the pole at $x = -1$ let b be the coefficient of $\frac{1}{(x+1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{15}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{2} \end{aligned}$$

Since the order of r at ∞ is $4 > 2$ then

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= 0 \\
\alpha_\infty^{-} &= 1
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{15}{(x^2-1)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
1	2	0	$\frac{5}{2}$	$-\frac{3}{2}$
-1	2	0	$\frac{5}{2}$	$-\frac{3}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = 1$ then

$$\begin{aligned}
d &= \alpha_\infty^{-} - \left(\alpha_{c_1}^{-} + \alpha_{c_2}^{+}\right) \\
&= 1 - (1) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x-c_1} \right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{+}}{x-c_2} \right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{3}{2(x-1)} + \frac{5}{2(x+1)} + (-)(0) \\
&= -\frac{3}{2(x-1)} + \frac{5}{2(x+1)} \\
&= \frac{x-4}{x^2-1}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(-\frac{3}{2(x-1)}+\frac{5}{2(x+1)}\right)(0)+\left(\left(\frac{3}{2(x-1)^2}-\frac{5}{2(x+1)^2}\right)+\left(-\frac{3}{2(x-1)}+\frac{5}{2(x+1)}\right)^2-\left(\frac{}{(x^2}\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z''=rz$ is

$$\begin{aligned} z_1(x) &= pe^{\int \omega\, dx} \\ &= \mathrm{e}^{\int \left(-\frac{3}{2(x-1)}+\frac{5}{2(x+1)}\right)dx} \\ &= \frac{(x+1)^{5/2}}{(x-1)^{3/2}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-6x}{x^2-1}\, dx} \\ &= z_1 e^{\frac{3\ln(x-1)}{2}+\frac{3\ln(x+1)}{2}} \\ &= z_1\left((x-1)^{3/2}(x+1)^{3/2}\right) \end{aligned}$$

Which simplifies to

$$y_1 = (x+1)^4$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-6x}{x^2-1}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{\mathrm{e}^{3\ln(x-1)+3\ln(x+1)}}{(y_1)^2}\, dx \\ &= y_1\left(-\frac{x(x^2+1)\,\mathrm{e}^{3\ln(x-1)+3\ln(x+1)}}{(x+1)^7(x-1)^3}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left((x+1)^4\right) + c_2\left((x+1)^4\left(-\frac{x(x^2+1)\,\mathrm{e}^{3\ln(x-1)+3\ln(x+1)}}{(x+1)^7(x-1)^3}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$(x^2-1)\left(\frac{d^2}{dx^2}y(x)\right)-6x\left(\frac{d}{dx}y(x)\right)+12y(x)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x)=-\frac{12y(x)}{x^2-1}+\frac{6\left(\frac{d}{dx}y(x)\right)x}{x^2-1}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x)-\frac{6\left(\frac{d}{dx}y(x)\right)x}{x^2-1}+\frac{12y(x)}{x^2-1}=0$

□ Check to see if x_0 is a regular singular point

- ○ Define functions

  $\left[P_2(x)=-\frac{6x}{x^2-1}, P_3(x)=\frac{12}{x^2-1}\right]$

- ○ $(x+1)\cdot P_2(x)$ is analytic at $x=-1$

  $\left((x+1)\cdot P_2(x)\right)\Big|_{x=-1}=-3$

- ○ $(x+1)^2\cdot P_3(x)$ is analytic at $x=-1$

  $\left((x+1)^2\cdot P_3(x)\right)\Big|_{x=-1}=0$

- ○ $x=-1$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=-1$

- Multiply by denominators

  $(x^2-1)\left(\frac{d^2}{dx^2}y(x)\right)-6x\left(\frac{d}{dx}y(x)\right)+12y(x)=0$

- Change variables using $x=u-1$ so that the regular singular point is at $u=0$

  $(u^2-2u)\left(\frac{d^2}{du^2}y(u)\right)+(-6u+6)\left(\frac{d}{du}y(u)\right)+12y(u)=0$

- Assume series solution for $y(u)$

  $y(u)=\sum_{k=0}^{\infty} a_k u^{k+r}$

□ Rewrite ODE with series expansions

- ○ Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$

  $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty} a_k(k+r)\,u^{k+r-1+m}$

- ○ Shift index using $k->k+1-m$

  $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,u^{k+r}$

- ○ Convert $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m=1..2$

  $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\,u^{k+r-2+m}$

- ○ Shift index using $k->k+2-m$

  $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\,u^{k+r}$

  Rewrite ODE with series expansions

  $-2a_0r(-4+r)\,u^{-1+r}+\left(\sum_{k=0}^{\infty}\left(-2a_{k+1}(k+1+r)(k+r-3)+a_k(k+r-3)(k+r-4)\right)u^{k+r}\right)$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$-2r(-4+r)=0$

- Values of r that satisfy the indicial equation
  $r \in \{0,4\}$
- Each term in the series must be 0, giving the recursion relation
  $(k+r-3)\left((-2k-2r-2)\,a_{k+1}+a_k(k+r-4)\right)=0$
- Recursion relation that defines series solution to ODE
  $a_{k+1}=\frac{a_k(k+r-4)}{2(k+1+r)}$
- Recursion relation for $r=0$; series terminates at $k=4$
  $a_{k+1}=\frac{a_k(k-4)}{2(k+1)}$
- Apply recursion relation for $k=0$
  $a_1=-2a_0$
- Apply recursion relation for $k=1$
  $a_2=-\frac{3a_1}{4}$
- Express in terms of a_0
  $a_2=\frac{3a_0}{2}$
- Apply recursion relation for $k=2$
  $a_3=-\frac{a_2}{3}$
- Express in terms of a_0
  $a_3=-\frac{a_0}{2}$
- Apply recursion relation for $k=3$
  $a_4=-\frac{a_3}{8}$
- Express in terms of a_0
  $a_4=\frac{a_0}{16}$
- Terminating series solution of the ODE for $r=0$. Use reduction of order to find the second linea
  $y(u)=a_0\cdot\left(1-2u+\frac{3}{2}u^2-\frac{1}{2}u^3+\frac{1}{16}u^4\right)$
- Revert the change of variables $u=x+1$
  $\left[y(x)=\frac{a_0(x-1)^4}{16}\right]$
- Recursion relation for $r=4$
  $a_{k+1}=\frac{a_k k}{2(k+5)}$
- Solution for $r=4$
  $\left[y(u)=\sum_{k=0}^{\infty} a_k u^{k+4}, a_{k+1}=\frac{a_k k}{2(k+5)}\right]$
- Revert the change of variables $u=x+1$
  $\left[y(x)=\sum_{k=0}^{\infty} a_k(x+1)^{k+4}, a_{k+1}=\frac{a_k k}{2(k+5)}\right]$
- Combine solutions and rename parameters
  $\left[y(x)=\frac{a_0(x-1)^4}{16}+\left(\sum_{k=0}^{\infty} b_k(x+1)^{4+k}\right), b_{k+1}=\frac{b_k k}{2(5+k)}\right]$

2.1.3 Problem 3

Internal problem ID [9175]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 3
Date solved : `Monday, January 27, 2025 at 05:51:44 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$\left(x^2+3\right) y''-7xy'+16y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.362 (sec)

Writing the ode as

$$\left(x^2+3\right) y''-7xy'+16y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2+3 \\ B &= -7x \\ C &= 16 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{-x^2-234}{4\left(x^2+3\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -x^2-234 \\ t &= 4\left(x^2+3\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{-x^2-234}{4\left(x^2+3\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.5: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^2+3)^2$. There is a pole at $x = i\sqrt{3}$ of order 2. There is a pole at $x = -i\sqrt{3}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{77}{16\left(x - i\sqrt{3}\right)^2} + \frac{77}{16\left(x + i\sqrt{3}\right)^2} + \frac{79i\sqrt{3}}{48\left(x - i\sqrt{3}\right)} - \frac{79i\sqrt{3}}{48\left(x + i\sqrt{3}\right)}$$

For the pole at $x = i\sqrt{3}$ let b be the coefficient of $\frac{1}{\left(x - i\sqrt{3}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{77}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{11}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{7}{4} \end{aligned}$$

For the pole at $x = -i\sqrt{3}$ let b be the coefficient of $\frac{1}{\left(x + i\sqrt{3}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{77}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{11}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{7}{4} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{-x^2 - 234}{4\left(x^2+3\right)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{1}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{-x^2 - 234}{4\left(x^2+3\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
$i\sqrt{3}$	2	0	$\frac{11}{4}$	$-\frac{7}{4}$
$-i\sqrt{3}$	2	0	$\frac{11}{4}$	$-\frac{7}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^-\right) \\
&= \frac{1}{2} - \left(-\frac{7}{2}\right) \\
&= 4
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2}\right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{7}{4\left(x-i\sqrt{3}\right)} - \frac{7}{4\left(x+i\sqrt{3}\right)} + (-)(0) \\
&= -\frac{7}{4\left(x-i\sqrt{3}\right)} - \frac{7}{4\left(x+i\sqrt{3}\right)} \\
&= -\frac{7x}{2x^2+6}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 4$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x^4 + a_3 x^3 + a_2 x^2 + a_1 x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\left(12x^2 + 6xa_3 + 2a_2\right) + 2\left(-\frac{7}{4\left(x - i\sqrt{3}\right)} - \frac{7}{4\left(x + i\sqrt{3}\right)}\right)\left(4x^3 + 3x^2 a_3 + 2xa_2 + a_1\right) + \left(\left(\frac{7}{4\left(x - i\sqrt{3}\right)^2}\right.\right.$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\left\{a_0 = \frac{27}{8}, a_1 = 0, a_2 = -9, a_3 = 0\right\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^4 - 9x^2 + \frac{27}{8}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \left(x^4 - 9x^2 + \frac{27}{8}\right) e^{\int \left(-\frac{7}{4\left(x - i\sqrt{3}\right)} - \frac{7}{4\left(x + i\sqrt{3}\right)}\right) dx} \\
&= \left(x^4 - 9x^2 + \frac{27}{8}\right) \frac{1}{\left(\left(i\sqrt{3} - x\right)\left(x + i\sqrt{3}\right)\right)^{7/4}} \\
&= \frac{8x^4 - 72x^2 + 27}{8\left(-x^2 - 3\right)^{7/4}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{-7x}{x^2+3} \, dx} \\
&= z_1 e^{\frac{7 \ln\left(x^2+3\right)}{4}} \\
&= z_1 \left(\left(x^2 + 3\right)^{7/4}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \left(\frac{1}{2} + \frac{i}{2}\right)\sqrt{2}\left(x^4 - 9x^2 + \frac{27}{8}\right)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-7x}{x^2+3}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{\frac{7\ln(x^2+3)}{2}}}{(y_1)^2}\,dx \\ &= y_1(\text{Expression too large to display}) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\left(\frac{1}{2}+\frac{i}{2}\right)\sqrt{2}\left(x^4-9x^2+\frac{27}{8}\right)\right) \\ &\quad + c_2\left(\left(\frac{1}{2}+\frac{i}{2}\right)\sqrt{2}\left(x^4-9x^2+\frac{27}{8}\right)(\text{Expression too large to display})\right) \end{aligned}$$

Will add steps showing solving for IC soon.

2.1.4 Problem 4

Internal problem ID [9176]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 4
Date solved : `Monday, January 27, 2025 at 05:51:45 PM`
CAS classification : `[_Gegenbauer]`

Solve

$$\left(x^{2}-1\right) y''+8 x y'+12 y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.183 (sec)

Writing the ode as

$$\left(x^{2}-1\right) y''+8 x y'+12 y=0 \tag{1}$$
$$A y''+B y'+C y=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^{2}-1 \\ B &= 8 x \\ C &= 12 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=y e^{\int \frac{B}{2 A}\, d x}$$

Then (2) becomes

$$z''(x)=r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2 A B'-2 B A'+B^{2}-4 A C}{4 A^{2}} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r=\frac{8}{\left(x^{2}-1\right)^{2}} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 8 \\ t &= \left(x^{2}-1\right)^{2} \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{8}{\left(x^{2}-1\right)^{2}}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.6: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 0 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (x^2 - 1)^2$. There is a pole at $x = 1$ of order 2. There is a pole at $x = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{2}{(x-1)^2} + \frac{2}{(x+1)^2} - \frac{2}{x-1} + \frac{2}{x+1}$$

For the pole at $x = 1$ let b be the coefficient of $\frac{1}{(x-1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1 \end{aligned}$$

For the pole at $x = -1$ let b be the coefficient of $\frac{1}{(x+1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1 \end{aligned}$$

Since the order of r at ∞ is $4 > 2$ then

$$\begin{aligned}[\sqrt{r}]_\infty &= 0\\ \alpha_\infty^+ &= 0\\ \alpha_\infty^- &= 1\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{8}{(x^2-1)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
1	2	0	2	-1
-1	2	0	2	-1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$ then

$$\begin{aligned}d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^+\right)\\ &= 1 - (1)\\ &= 0\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x-c_2}\right) + (-)[\sqrt{r}]_\infty\\ &= -\frac{1}{x-1} + \frac{2}{x+1} + (-)\,(0)\\ &= -\frac{1}{x-1} + \frac{2}{x+1}\\ &= \frac{x-3}{x^2-1}\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned}(0) + 2\left(-\frac{1}{x-1} + \frac{2}{x+1}\right)(0) + \left(\left(\frac{1}{(x-1)^2} - \frac{2}{(x+1)^2}\right) + \left(-\frac{1}{x-1} + \frac{2}{x+1}\right)^2 - \left(\frac{8}{(x^2-1)^2}\right)\right) &= 0\\ 0 &= 0\end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= pe^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(-\frac{1}{x-1}+\frac{2}{x+1}\right)dx} \\
&= \frac{(x+1)^2}{x-1}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{8x}{x^2-1}\, dx} \\
&= z_1 e^{-2\ln(x-1)-2\ln(x+1)} \\
&= z_1 \left(\frac{1}{(x-1)^2 (x+1)^2}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{1}{(x-1)^3}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2} \, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{8x}{x^2-1}\, dx}}{(y_1)^2} \, dx \\
&= y_1 \int \frac{e^{-4\ln(x-1)-4\ln(x+1)}}{(y_1)^2} \, dx \\
&= y_1 \left(-\frac{(x+1)(3x^2+1)(x-1)^4 \,\mathrm{e}^{-4\ln(x-1)-4\ln(x+1)}}{3}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{1}{(x-1)^3}\right) + c_2 \left(\frac{1}{(x-1)^3} \left(-\frac{(x+1)(3x^2+1)(x-1)^4 \,\mathrm{e}^{-4\ln(x-1)-4\ln(x+1)}}{3}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$(x^2-1)\left(\frac{d^2}{dx^2}y(x)\right)+8x\left(\frac{d}{dx}y(x)\right)+12y(x)=0$

- Highest derivative means the order of the ODE is 2

$\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

$\frac{d^2}{dx^2}y(x)=-\frac{12y(x)}{x^2-1}-\frac{8\left(\frac{d}{dx}y(x)\right)x}{x^2-1}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

$\frac{d^2}{dx^2}y(x)+\frac{8\left(\frac{d}{dx}y(x)\right)x}{x^2-1}+\frac{12y(x)}{x^2-1}=0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

  $\left[P_2(x)=\frac{8x}{x^2-1}, P_3(x)=\frac{12}{x^2-1}\right]$

  ◦ $(x+1)\cdot P_2(x)$ is analytic at $x=-1$

  $\left((x+1)\cdot P_2(x)\right)\Big|_{x=-1}=4$

  ◦ $(x+1)^2\cdot P_3(x)$ is analytic at $x=-1$

  $\left((x+1)^2\cdot P_3(x)\right)\Big|_{x=-1}=0$

  ◦ $x=-1$is a regular singular point

Check to see if x_0 is a regular singular point

$x_0=-1$

- Multiply by denominators

$(x^2-1)\left(\frac{d^2}{dx^2}y(x)\right)+8x\left(\frac{d}{dx}y(x)\right)+12y(x)=0$

- Change variables using $x=u-1$ so that the regular singular point is at $u=0$

$(u^2-2u)\left(\frac{d^2}{du^2}y(u)\right)+(8u-8)\left(\frac{d}{du}y(u)\right)+12y(u)=0$

- Assume series solution for $y(u)$

$y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$

  $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,u^{k+r-1+m}$

  ◦ Shift index using $k->k+1-m$

  $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,u^{k+r}$

  ◦ Convert $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m=1..2$

  $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)(k+r-1)\,u^{k+r-2+m}$

  ◦ Shift index using $k->k+2-m$

  $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=-2+m}^{\infty}a_{k+2-m}(k+2-m+r)(k+1-m+r)\,u^{k+r}$

Rewrite ODE with series expansions

$-2a_0r(3+r)\,u^{-1+r}+\left(\sum_{k=0}^{\infty}\left(-2a_{k+1}(k+1+r)(k+r+4)+a_k(k+r+4)(k+r+3)\right)u^{k+r}\right)=0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$-2r(3+r)=0$

- Values of r that satisfy the indicial equation
  $r \in \{-3, 0\}$
- Each term in the series must be 0, giving the recursion relation
  $(k+r+4)\left((-2k-2r-2)\,a_{k+1}+a_k(k+r+3)\right)=0$
- Recursion relation that defines series solution to ODE
  $a_{k+1}=\frac{a_k(k+r+3)}{2(k+1+r)}$
- Recursion relation for $r=-3$
  $a_{k+1}=\frac{a_k k}{2(k-2)}$
- Series not valid for $r=-3$, division by 0 in the recursion relation at $k=2$
  $a_{k+1}=\frac{a_k k}{2(k-2)}$
- Recursion relation for $r=0$
  $a_{k+1}=\frac{a_k(k+3)}{2(k+1)}$
- Solution for $r=0$
  $\left[y(u)=\sum_{k=0}^{\infty} a_k u^k, a_{k+1}=\frac{a_k(k+3)}{2(k+1)}\right]$
- Revert the change of variables $u=x+1$
  $\left[y(x)=\sum_{k=0}^{\infty} a_k (x+1)^k, a_{k+1}=\frac{a_k(k+3)}{2(k+1)}\right]$

2.1.5 Problem 5

Internal problem ID [9177]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 5
Date solved : `Monday, January 27, 2025 at 05:51:45 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$3y'' + xy' - 4y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.229 (sec)

Writing the ode as

$$3y'' + xy' - 4y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 3 \\ B &= x \\ C &= -4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 + 54}{36} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2 + 54 \\ t &= 36 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2}{36} + \frac{3}{2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1, 2\}$,$\{1, 3\}$,$\{2\}$,$\{3\}$,$\{3, 4\}$,$\{1, 2, 5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.8: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 2 \\ &= -2 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x}{6} + \frac{9}{2x} - \frac{243}{4x^3} + \frac{6561}{4x^5} - \frac{885735}{16x^7} + \frac{33480783}{16x^9} - \frac{2711943423}{32x^{11}} + \frac{115063885233}{32x^{13}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{6}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= \frac{x}{6} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{x^2}{36}$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 + 54}{36} \\ &= Q + \frac{R}{36} \\ &= \left(\frac{x^2}{36} + \frac{3}{2}\right) + (0) \\ &= \frac{x^2}{36} + \frac{3}{2} \end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is $\frac{3}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(\frac{3}{2}\right) - (0) \\ &= \frac{3}{2} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{x}{6} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{\frac{3}{2}}{\frac{1}{6}} - 1\right) &= 4 \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{\frac{3}{2}}{\frac{1}{6}} - 1\right) &= -5 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2}{36} + \frac{3}{2}$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-2	$\frac{x}{6}$	4	-5

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = 4$, and since there are no poles, then

$$\begin{aligned} d &= \alpha_\infty^+ \\ &= 4 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= (+)[\sqrt{r}]_\infty \\ &= 0 + \left(\frac{x}{6}\right) \\ &= \frac{x}{6} \\ &= \frac{x}{6} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 4$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}$$

Let

$$p(x) = x^4 + a_3x^3 + a_2x^2 + a_1x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\left(12x^2 + 6xa_3 + 2a_2\right) + 2\left(\frac{x}{6}\right)\left(4x^3 + 3x^2a_3 + 2xa_2 + a_1\right) + \left(\left(\frac{1}{6}\right) + \left(\frac{x}{6}\right)^2 - \left(\frac{x^2}{36} + \frac{3}{2}\right)\right) = 0$$

$$-\frac{a_3x^3}{3} + \frac{2(18-a_2)\,x^2}{3} + (-a_1 + 6a_3)\,x - \frac{4a_0}{3} + 2a_2 = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 27, a_1 = 0, a_2 = 18, a_3 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^4 + 18x^2 + 27$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= pe^{\int \omega\,dx} \\ &= \left(x^4 + 18x^2 + 27\right)e^{\int \frac{x}{6}dx} \\ &= \left(x^4 + 18x^2 + 27\right)e^{\frac{x^2}{12}} \\ &= \left(x^4 + 18x^2 + 27\right)e^{\frac{x^2}{12}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{x}{3}\,dx} \\ &= z_1 e^{-\frac{x^2}{12}} \\ &= z_1\left(e^{-\frac{x^2}{12}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = x^4 + 18x^2 + 27$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x}{3}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{x^2}{6}}}{(y_1)^2}\,dx \\
&= y_1 \left(\int \frac{\mathrm{e}^{-\frac{x^2}{6}}}{(x^4+18x^2+27)^2}dx\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 (x^4 + 18x^2 + 27) + c_2 \left(x^4 + 18x^2 + 27\left(\int \frac{\mathrm{e}^{-\frac{x^2}{6}}}{(x^4+18x^2+27)^2}dx\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

2.1.6 Problem 6

Internal problem ID [9178]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 6
Date solved : `Monday, January 27, 2025 at 05:51:46 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$5y'' - 2xy' + 10y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.264 (sec)

Writing the ode as

$$5y'' - 2xy' + 10y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 5 \\ B &= -2x \\ C &= 10 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 - 55}{25} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2 - 55 \\ t &= 25 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2}{25} - \frac{11}{5}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.9: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 2 \\ &= -2 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x}{5} - \frac{11}{2x} - \frac{605}{8x^3} - \frac{33275}{16x^5} - \frac{9150625}{128x^7} - \frac{704598125}{256x^9} - \frac{116258690625}{1024x^{11}} - \frac{10048072546875}{2048x^{13}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{5}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= \frac{x}{5} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{x^2}{25}$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 - 55}{25} \\ &= Q + \frac{R}{25} \\ &= \left(\frac{x^2}{25} - \frac{11}{5}\right) + (0) \\ &= \frac{x^2}{25} - \frac{11}{5} \end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is $-\frac{11}{5}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{11}{5}\right) - (0) \\ &= -\frac{11}{5} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{x}{5} \\ \alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{11}{5}}{\frac{1}{5}} - 1\right) &&= -6 \\ \alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{11}{5}}{\frac{1}{5}} - 1\right) &&= 5 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2}{25} - \frac{11}{5}$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
-2	$\frac{x}{5}$	-6	5

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 5$, and since there are no poles then

$$\begin{aligned} d &= \alpha_\infty^- \\ &= 5 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= (-)[\sqrt{r}]_\infty \\ &= 0 + (-)\left(\frac{x}{5}\right) \\ &= -\frac{x}{5} \\ &= -\frac{x}{5} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 5$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}$$

Let

$$p(x) = x^5 + a_4x^4 + a_3x^3 + a_2x^2 + a_1x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\left(20x^3 + 12x^2a_4 + 6xa_3 + 2a_2\right) + 2\left(-\frac{x}{5}\right)\left(5x^4 + 4x^3a_4 + 3x^2a_3 + 2xa_2 + a_1\right) + \left(\left(-\frac{1}{5}\right) + \left(-\frac{x}{5}\right)^2 - \left(\frac{x^2}{25} -\right.\right.$$

$$\frac{2a_4x^4}{5} + \frac{4(25+a_3)\,x^3}{5} + \frac{6(a_2+10a_4)\,x^2}{5} + \frac{2(4a_1+15a_3)\,x}{5} + 2a_0 +$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\left\{a_0 = 0, a_1 = \frac{375}{4}, a_2 = 0, a_3 = -25, a_4 = 0\right\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^5 - 25x^3 + \frac{375}{4}x$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= pe^{\int \omega\, dx} \\ &= \left(x^5 - 25x^3 + \frac{375}{4}x\right)e^{\int -\frac{x}{5}dx} \\ &= \left(x^5 - 25x^3 + \frac{375}{4}x\right)e^{-\frac{x^2}{10}} \\ &= \frac{\left(4x^5 - 100x^3 + 375x\right)e^{-\frac{x^2}{10}}}{4} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-2x}{5}\, dx} \\ &= z_1 e^{\frac{x^2}{10}} \\ &= z_1\left(e^{\frac{x^2}{10}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = x^5 - 25x^3 + \frac{375}{4}x$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-2x}{5}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{\frac{x^2}{5}}}{(y_1)^2}\,dx \\ &= y_1 \left(\int \frac{e^{\frac{x^2}{5}}}{\left(x^5 - 25x^3 + \frac{375}{4}x\right)^2}dx\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(x^5 - 25x^3 + \frac{375}{4}x\right) + c_2\left(x^5 - 25x^3 + \frac{375}{4}x\left(\int \frac{e^{\frac{x^2}{5}}}{\left(x^5 - 25x^3 + \frac{375}{4}x\right)^2}dx\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$5\frac{d^2}{dx^2}y(x) - 2x\left(\frac{d}{dx}y(x)\right) + 10y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = \frac{2x\left(\frac{d}{dx}y(x)\right)}{5} - 2y(x)$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x) - \frac{2x\left(\frac{d}{dx}y(x)\right)}{5} + 2y(x) = 0$

- Multiply by denominators

  $5\frac{d^2}{dx^2}y(x) - 2x\left(\frac{d}{dx}y(x)\right) + 10y(x) = 0$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^k$

- □ Rewrite DE with series expansions

  - Convert $x \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion

    $x \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k k\, x^k$

  - Convert $\frac{d^2}{dx^2}y(x)$ to series expansion

    $\frac{d^2}{dx^2}y(x) = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$

  - Shift index using $k->k+2$

$\frac{d^2}{dx^2}y(x) = \sum_{k=0}^{\infty} a_{k+2}(k+2)(k+1)x^k$

Rewrite DE with series expansions

$\sum_{k=0}^{\infty} (5a_{k+2}(k+2)(k+1) - 2a_k(k-5))x^k = 0$

- Each term in the series must be 0, giving the recursion relation

  $5(k^2+3k+2)a_{k+2} - 2a_k(k-5) = 0$

- Recursion relation that defines the series solution to the ODE

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^k, a_{k+2} = \frac{2a_k(k-5)}{5(k^2+3k+2)}\right]$

Solve

$$y'' - x^2 y' - 3xy = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.308 (sec)

Writing the ode as

$$y'' - x^2 y' - 3xy = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -x^2 \\ C &= -3x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x(x^3+8)}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x(x^3+8) \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x(x^3+8)}{4}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.11: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 4 \\ &= -4 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -4 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -4$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{4}{2} = 2$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{2} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^2$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x^2}{2} + \frac{2}{x} - \frac{4}{x^4} + \frac{16}{x^7} - \frac{80}{x^{10}} + \frac{448}{x^{13}} - \frac{2688}{x^{16}} + \frac{16896}{x^{19}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 2$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{2} a_i x^i \\ &= \frac{x^2}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^1 = x$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{x^4}{4}$$

This shows that the coefficient of x in the above is 0. Now we need to find the coefficient of x in r. How this is done depends on if $v = 0$ or not. Since $v = 2$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of x in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x(x^3+8)}{4} \\ &= Q + \frac{R}{4} \\ &= \left(\frac{1}{4}x^4 + 2x\right) + (0) \\ &= \frac{1}{4}x^4 + 2x \end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is 2. Now b can be found.

$$\begin{aligned} b &= (2) - (0) \\ &= 2 \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{x^2}{2} \\ \alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{2}{\frac{1}{2}} - 2\right) &&= 1 \\ \alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{2}{\frac{1}{2}} - 2\right) &&= -3 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x(x^3+8)}{4}$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
-4	$\frac{x^2}{2}$	1	-3

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = 1$, and since there are no poles, then

$$\begin{aligned} d &= \alpha_\infty^+ \\ &= 1 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= (+)[\sqrt{r}]_\infty \\ &= 0 + \left(\frac{x^2}{2}\right) \\ &= \frac{x^2}{2} \\ &= \frac{x^2}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{x^2}{2}\right)(1) + \left((x) + \left(\frac{x^2}{2}\right)^2 - \left(\frac{x(x^3+8)}{4}\right)\right) = 0$$
$$-xa_0 = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= pe^{\int \omega\, dx} \\ &= (x)\, e^{\int \frac{x^2}{2} dx} \\ &= (x)\, e^{\frac{x^3}{6}} \\ &= x\, e^{\frac{x^3}{6}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-x^2}{1}\, dx} \\ &= z_1 e^{\frac{x^3}{6}} \\ &= z_1\left(e^{\frac{x^3}{6}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{\frac{x^3}{3}} x$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-x^2}{1}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{\frac{x^3}{3}}}{(y_1)^2}\, dx \\
&= y_1 \left(\int \frac{\mathrm{e}^{-\frac{x^3}{3}}}{x^2} dx\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{\frac{x^3}{3}} x\right) + c_2 \left(\mathrm{e}^{\frac{x^3}{3}} x \left(\int \frac{\mathrm{e}^{-\frac{x^3}{3}}}{x^2} dx\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$\frac{d^2}{dx^2} y(x) - x^2 \left(\frac{d}{dx} y(x)\right) - 3xy(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2} y(x)$

2.1.8 Problem 8

Internal problem ID [9180]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 8
Date solved : `Monday, January 27, 2025 at 05:51:48 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$\left(x^2+1\right) y''+2xy'-2y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.280 (sec)

Writing the ode as

$$\left(x^2+1\right) y''+2xy'-2y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2+1 \\ B &= 2x \\ C &= -2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r=\frac{2x^2+3}{\left(x^2+1\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 2x^2+3 \\ t &= \left(x^2+1\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{2x^2+3}{\left(x^2+1\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.13: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (x^2+1)^2$. There is a pole at $x = i$ of order 2. There is a pole at $x = -i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4(x-i)^2} - \frac{1}{4(x+i)^2} - \frac{5i}{4(x-i)} + \frac{5i}{4(x+i)}$$

For the pole at $x = i$ let b be the coefficient of $\frac{1}{(x-i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

For the pole at $x = -i$ let b be the coefficient of $\frac{1}{(x+i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{2x^2+3}{(x^2+1)^2}$$

Since the $\gcd(s,t)=1$. This gives $b=2$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -1
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{2x^2+3}{(x^2+1)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
i	2	0	$\frac{1}{2}$	$\frac{1}{2}$
$-i$	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	2	-1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = 2$ then

$$\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^- + \alpha_{c_2}^-\right) \\
&= 2 - (1) \\
&= 1
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2}\right) + (+)[\sqrt{r}]_\infty \\
&= \frac{1}{2x-2i} + \frac{1}{2x+2i} + (0) \\
&= \frac{1}{2x-2i} + \frac{1}{2x+2i} \\
&= \frac{x}{x^2+1}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{2x-2i} + \frac{1}{2x+2i}\right)(1) + \left(\left(-\frac{1}{2(x-i)^2} - \frac{1}{2(x+i)^2}\right) + \left(\frac{1}{2x-2i} + \frac{1}{2x+2i}\right)^2 - \left(\frac{2x^2+3}{(x^2+1)^2}\right.\right.$$
$$-\frac{2(x^2+1)\,a_0}{(-x+i)^2\,(x+i)^2}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx} \\
&= (x)\, e^{\int \left(\frac{1}{2x-2i} + \frac{1}{2x+2i}\right) dx} \\
&= (x)\sqrt{(-x+i)(x+i)} \\
&= x\sqrt{-x^2-1}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{2x}{x^2+1}\, dx} \\
&= z_1 e^{-\frac{\ln(x^2+1)}{2}} \\
&= z_1\left(\frac{1}{\sqrt{x^2+1}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = ix$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{2x}{x^2+1}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-\ln(x^2+1)}}{(y_1)^2}\, dx \\
&= y_1\left(\arctan(x) + \frac{1}{x}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(ix) + c_2\left(ix\left(\arctan(x) + \frac{1}{x}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

2.1.9 Problem 9

Internal problem ID [9181]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 9
Date solved : `Monday, January 27, 2025 at 05:51:48 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$y'' + xy' - 2y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.227 (sec)

Writing the ode as

$$y'' + xy' - 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= x \\ C &= -2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 + 10}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2 + 10 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2}{4} + \frac{5}{2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.14: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 2 \\ &= -2 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x}{2} + \frac{5}{2x} - \frac{25}{4x^3} + \frac{125}{4x^5} - \frac{3125}{16x^7} + \frac{21875}{16x^9} - \frac{328125}{32x^{11}} + \frac{2578125}{32x^{13}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 1$ gives

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\
&= \frac{x}{2} \qquad (10)
\end{aligned}
$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$
\left([\sqrt{r}]_\infty\right)^2 = \frac{x^2}{4}
$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$
r = Q + \frac{R}{t}
$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{x^2 + 10}{4} \\
&= Q + \frac{R}{4} \\
&= \left(\frac{x^2}{4} + \frac{5}{2}\right) + (0) \\
&= \frac{x^2}{4} + \frac{5}{2}
\end{aligned}
$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is $\frac{5}{2}$. Now b can be found.

$$
\begin{aligned}
b &= \left(\frac{5}{2}\right) - (0) \\
&= \frac{5}{2}
\end{aligned}
$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \frac{x}{2} \\
\alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{\frac{5}{2}}{\frac{1}{2}} - 1\right) &= 2 \\
\alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{\frac{5}{2}}{\frac{1}{2}} - 1\right) &= -3
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{x^2}{4} + \frac{5}{2}
$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
-2	$\frac{x}{2}$	2	-3

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = 2$, and since there are no poles, then

$$\begin{aligned} d &= \alpha_\infty^+ \\ &= 2 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= (+)[\sqrt{r}]_\infty \\ &= 0 + \left(\frac{x}{2}\right) \\ &= \frac{x}{2} \\ &= \frac{x}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 2$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = x^2 + a_1 x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (2) + 2\left(\frac{x}{2}\right)(2x + a_1) + \left(\left(\frac{1}{2}\right) + \left(\frac{x}{2}\right)^2 - \left(\frac{x^2}{4} + \frac{5}{2}\right)\right) &= 0 \\ -a_1 x - 2a_0 + 2 &= 0 \end{aligned}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 1, a_1 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^2 + 1$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega\, dx} \\ &= (x^2 + 1)\, e^{\int \frac{x}{2} dx} \\ &= (x^2 + 1)\, e^{\frac{x^2}{4}} \\ &= (x^2 + 1)\, e^{\frac{x^2}{4}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{x}{1}\, dx} \\ &= z_1 e^{-\frac{x^2}{4}} \\ &= z_1\left(e^{-\frac{x^2}{4}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = x^2 + 1$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{x}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{-\frac{x^2}{2}}}{(y_1)^2}\,dx \\ &= y_1 \left(\int \frac{e^{-\frac{x^2}{2}}}{(x^2+1)^2} dx \right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 (x^2 + 1) + c_2 \left(x^2 + 1 \left(\int \frac{e^{-\frac{x^2}{2}}}{(x^2+1)^2} dx \right) \right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$\frac{d^2}{dx^2}y(x) + x\left(\frac{d}{dx}y(x)\right) - 2y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^k$

- □ Rewrite DE with series expansions
  - Convert $x \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion

    $x \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k k\, x^k$

  - Convert $\frac{d^2}{dx^2}y(x)$ to series expansion

    $\frac{d^2}{dx^2}y(x) = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$

  - Shift index using $k- >k+2$

    $\frac{d^2}{dx^2}y(x) = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$

  Rewrite DE with series expansions

  $\sum_{k=0}^{\infty} \left(a_{k+2}(k+2)\,(k+1) + a_k(k-2)\right) x^k = 0$

- Each term in the series must be 0, giving the recursion relation

  $(k^2 + 3k + 2)\, a_{k+2} + a_k(k-2) = 0$

- Recursion relation; series terminates at $k = 2$

$a_{k+2} = -\frac{a_k(k-2)}{k^2+3k+2}$

- Apply recursion relation for $k = 0$

  $a_2 = a_0$

- Terminating series solution of the ODE. Use reduction of order to find the second linearly indepe

  $y(x) = A_2x^2 + A_1x + a_0$

2.1.10 Problem 10

Internal problem ID [9182]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 10
Date solved : `Monday, January 27, 2025 at 05:51:49 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$\left(x^{2}-6x+10\right)y''-4(x-3)\,y'+6y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.305 (sec)

Writing the ode as

$$\left(x^{2}-6x+10\right)y''+(-4x+12)\,y'+6y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^{2}-6x+10\\ B &= -4x+12\\ C &= 6 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=y e^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t}\\ &= \frac{2AB'-2BA'+B^{2}-4AC}{4A^{2}} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{-8}{\left(x^{2}-6x+10\right)^{2}} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -8\\ t &= \left(x^{2}-6x+10\right)^{2} \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(-\frac{8}{\left(x^{2}-6x+10\right)^{2}}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.16: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 0 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (x^2 - 6x + 10)^2$. There is a pole at $x = 3 + i$ of order 2. There is a pole at $x = 3 - i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{2}{(x-3-i)^2} + \frac{2}{(x-3+i)^2} + \frac{2i}{x-3-i} - \frac{2i}{x-3+i}$$

For the pole at $x = 3 + i$ let b be the coefficient of $\frac{1}{(x-3-i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1 \end{aligned}$$

For the pole at $x = 3 - i$ let b be the coefficient of $\frac{1}{(x-3+i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1 \end{aligned}$$

Since the order of r at ∞ is $4 > 2$ then

$$\begin{aligned}[\sqrt{r}]_\infty &= 0\\ \alpha_\infty^+ &= 0\\ \alpha_\infty^- &= 1\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = -\frac{8}{(x^2 - 6x + 10)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
$3+i$	2	0	2	-1
$3-i$	2	0	2	-1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$ then

$$\begin{aligned}d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^+\right)\\ &= 1 - (1)\\ &= 0\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x-c_2}\right) + (-)[\sqrt{r}]_\infty\\ &= -\frac{1}{x-3-i} + \frac{2}{x-3+i} + (-)(0)\\ &= -\frac{1}{x-3-i} + \frac{2}{x-3+i}\\ &= \frac{x-3-3i}{x^2-6x+10}\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{x-3-i} + \frac{2}{x-3+i}\right)(0) + \left(\left(\frac{1}{(x-3-i)^2} - \frac{2}{(x-3+i)^2}\right) + \left(-\frac{1}{x-3-i} + \frac{2}{x-3+i}\right)^2\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(-\frac{1}{x-3-i}+\frac{2}{x-3+i}\right) dx} \\
&= \frac{\left(x^2-6x+10\right)^2}{\left(ix-3i+1\right)^3}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-4x+12}{x^2-6x+10}\, dx} \\
&= z_1 e^{\ln\left(x^2-6x+10\right)} \\
&= z_1 \left(x^2-6x+10\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{\left(x^2-6x+10\right)^3}{\left(ix-3i+1\right)^3}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-4x+12}{x^2-6x+10}\, dx}}{\left(y_1\right)^2}\, dx \\
&= y_1 \int \frac{e^{2\ln\left(x^2-6x+10\right)}}{\left(y_1\right)^2}\, dx \\
&= y_1 \left(\frac{x^2-6x+\frac{26}{3}}{\left(x-3+i\right)^3}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{\left(x^2-6x+10\right)^3}{\left(ix-3i+1\right)^3}\right) + c_2 \left(\frac{\left(x^2-6x+10\right)^3}{\left(ix-3i+1\right)^3}\left(\frac{x^2-6x+\frac{26}{3}}{\left(x-3+i\right)^3}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

2.1.11 Problem 11

Internal problem ID [9183]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 11
Date solved : `Monday, January 27, 2025 at 05:51:50 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$\left(x^2+6x\right)y''+(3x+9)\,y'-3y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.206 (sec)

Writing the ode as

$$\left(x^2+6x\right)y''+(3x+9)\,y'-3y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2+6x \\ B &= 3x+9 \\ C &= -3 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r=\frac{15x^2+90x-27}{4\left(x^2+6x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 15x^2+90x-27 \\ t &= 4\left(x^2+6x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{15x^2+90x-27}{4\left(x^2+6x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.17: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^2 + 6x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -6$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{3}{16x^2} + \frac{11}{16x} - \frac{11}{16\,(x+6)} - \frac{3}{16\,(x+6)^2}$$

For the pole at $x = -6$ let b be the coefficient of $\frac{1}{(x+6)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{4} \end{aligned}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{4} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{15x^2 + 90x - 27}{4\left(x^2 + 6x\right)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{15}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{2} \\ \alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{15x^2 + 90x - 27}{4\left(x^2 + 6x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
-6	2	0	$\frac{3}{4}$	$\frac{1}{4}$
0	2	0	$\frac{3}{4}$	$\frac{1}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{5}{2}$	$-\frac{3}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{5}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^+ - \left(\alpha_{c_1}^+ + \alpha_{c_2}^+\right) \\ &= \frac{5}{2} - \left(\frac{3}{2}\right) \\ &= 1 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1} \right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x-c_2} \right) + (+)[\sqrt{r}]_\infty \\ &= \frac{3}{4\left(x+6\right)} + \frac{3}{4x} + (0) \\ &= \frac{3}{4\left(x+6\right)} + \frac{3}{4x} \\ &= \frac{\frac{3x}{2} + \frac{9}{2}}{x\left(x+6\right)} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r) p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{3}{4(x+6)} + \frac{3}{4x}\right)(1) + \left(\left(-\frac{3}{4(x+6)^2} - \frac{3}{4x^2}\right) + \left(\frac{3}{4(x+6)} + \frac{3}{4x}\right)^2 - \left(\frac{15x^2 + 90x - 27}{4(x^2+6x)^2}\right)\right) = \frac{9 - 3a_0}{x(x+6)} = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 3\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x + 3$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= (x+3) \, e^{\int \left(\frac{3}{4(x+6)} + \frac{3}{4x}\right) dx} \\
&= (x+3) \, (x(x+6))^{3/4} \\
&= (x+3) \, (x(x+6))^{3/4}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{3x+9}{x^2+6x} \, dx} \\
&= z_1 e^{-\frac{3\ln(x(x+6))}{4}} \\
&= z_1 \left(\frac{1}{(x(x+6))^{3/4}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = x + 3$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{3x+9}{x^2+6x} \, dx}}{(y_1)^2} \, dx \\
&= y_1 \int \frac{e^{-\frac{3\ln(x(x+6))}{2}}}{(y_1)^2} \, dx \\
&= y_1 \left(-\frac{(x+6) \, x(2x^2 + 12x + 9)}{81 (x+3) (x(x+6))^{3/2}}\right)
\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(x+3) + c_2\left(x + 3\left(-\frac{(x+6)\,x(2x^2+12x+9)}{81\,(x+3)\,(x\,(x+6))^{3/2}}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$(x^2+6x)\left(\frac{d^2}{dx^2}y(x)\right) + (3x+9)\left(\frac{d}{dx}y(x)\right) - 3y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$
- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = \frac{3y(x)}{x(6+x)} - \frac{3(x+3)\left(\frac{d}{dx}y(x)\right)}{x(6+x)}$
- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x) + \frac{3(x+3)\left(\frac{d}{dx}y(x)\right)}{x(6+x)} - \frac{3y(x)}{x(6+x)} = 0$

☐ Check to see if x_0 is a regular singular point

- ○ Define functions

  $\left[P_2(x) = \frac{3(x+3)}{x(6+x)}, P_3(x) = -\frac{3}{x(6+x)}\right]$
- ○ $(6+x)\cdot P_2(x)$ is analytic at $x=-6$

  $\left((6+x)\cdot P_2(x)\right)\Big|_{x=-6} = \frac{3}{2}$
- ○ $(6+x)^2\cdot P_3(x)$ is analytic at $x=-6$

  $\left((6+x)^2\cdot P_3(x)\right)\Big|_{x=-6} = 0$
- ○ $x=-6$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = -6$

- Multiply by denominators

  $x(6+x)\left(\frac{d^2}{dx^2}y(x)\right) + (3x+9)\left(\frac{d}{dx}y(x)\right) - 3y(x) = 0$
- Change variables using $x = u-6$ so that the regular singular point is at $u=0$

  $(u^2-6u)\left(\frac{d^2}{du^2}y(u)\right) + (3u-9)\left(\frac{d}{du}y(u)\right) - 3y(u) = 0$
- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

☐ Rewrite ODE with series expansions

- ○ Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..1$

  $u^m\cdot\left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,u^{k+r-1+m}$
- ○ Shift index using $k->k+1-m$

  $u^m\cdot\left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,u^{k+r}$
- ○ Convert $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m = 1..2$

$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, u^{k+r-2+m}$

- Shift index using $k->k+2-m$

  $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\, u^{k+r}$

  Rewrite ODE with series expansions

  $-3a_0r(1+2r)\, u^{-1+r} + \left(\sum_{k=0}^{\infty} (-3a_{k+1}(k+1+r)(2k+3+2r) + a_k(k+r+3)(k+r-1))\, u^{k+r}\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $-3r(1+2r) = 0$
- Values of r that satisfy the indicial equation

  $r \in \{0, -\frac{1}{2}\}$
- Each term in the series must be 0, giving the recursion relation

  $-6(k+1+r)\left(k+\frac{3}{2}+r\right)a_{k+1} + a_k(k+r+3)(k+r-1) = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+1} = \frac{a_k(k+r+3)(k+r-1)}{3(k+1+r)(2k+3+2r)}$
- Recursion relation for $r=0$; series terminates at $k=1$

  $a_{k+1} = \frac{a_k(k+3)(k-1)}{3(k+1)(2k+3)}$
- Apply recursion relation for $k=0$

  $a_1 = -\frac{a_0}{3}$
- Terminating series solution of the ODE for $r=0$. Use reduction of order to find the second li

  $y(u) = a_0 \cdot \left(1-\frac{u}{3}\right)$
- Revert the change of variables $u = 6+x$

  $\left[y(x) = a_0\left(-\frac{x}{3}-1\right)\right]$
- Recursion relation for $r = -\frac{1}{2}$

  $a_{k+1} = \frac{a_k\left(k+\frac{5}{2}\right)\left(k-\frac{3}{2}\right)}{3\left(k+\frac{1}{2}\right)(2k+2)}$
- Solution for $r = -\frac{1}{2}$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k-\frac{1}{2}}, a_{k+1} = \frac{a_k\left(k+\frac{5}{2}\right)\left(k-\frac{3}{2}\right)}{3\left(k+\frac{1}{2}\right)(2k+2)}\right]$
- Revert the change of variables $u = 6+x$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k(6+x)^{k-\frac{1}{2}}, a_{k+1} = \frac{a_k\left(k+\frac{5}{2}\right)\left(k-\frac{3}{2}\right)}{3\left(k+\frac{1}{2}\right)(2k+2)}\right]$
- Combine solutions and rename parameters

  $\left[y(x) = a_0\left(-\frac{x}{3}-1\right) + \left(\sum_{k=0}^{\infty} b_k(6+x)^{k-\frac{1}{2}}\right), b_{k+1} = \frac{b_k\left(k+\frac{5}{2}\right)\left(k-\frac{3}{2}\right)}{3\left(k+\frac{1}{2}\right)(2k+2)}\right]$

Date solved : `Monday, January 27, 2025 at 05:51:50 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$ty'' + (t^2 - 1)\,y' + t^2 y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.304 (sec)

Writing the ode as

$$ty'' + (t^2 - 1)\,y' + t^2 y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= t \\ B &= t^2 - 1 \\ C &= t^2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(t) = ye^{\int \frac{B}{2A}\,dt}$$

Then (2) becomes

$$z''(t) = rz(t) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{t^4 - 4t^3 + 3}{4t^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= t^4 - 4t^3 + 3 \\ t &= 4t^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(t) = \left(\frac{t^4 - 4t^3 + 3}{4t^2}\right) z(t) \tag{7}$$

Equation (7) is now solved. After finding $z(t)$ then y is found using the inverse transformation

$$y = z(t)\, e^{-\int \frac{B}{2A}\, dt}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.19: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 4 \\ &= -2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4t^2$. There is a pole at $t = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{t^2}{4} - t + \frac{3}{4t^2}$$

For the pole at $t = 0$ let b be the coefficient of $\frac{1}{t^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving t^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i t^i \\ &= \sum_{i=0}^{1} a_i t^i \end{aligned} \tag{8}$$

Let a be the coefficient of $t^v = t^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{t}{2} - 1 - \frac{1}{t} - \frac{2}{t^2} - \frac{17}{4t^3} - \frac{25}{2t^4} - \frac{75}{2t^5} - \frac{117}{t^6} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i t^i \\ &= -1 + \frac{t}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $t^{v-1} = t^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = 1 - t + \frac{1}{4}t^2$$

This shows that the coefficient of 1 in the above is 1. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{t^4 - 4t^3 + 3}{4t^2} \\ &= Q + \frac{R}{4t^2} \\ &= \left(\frac{1}{4}t^2 - t\right) + \left(\frac{3}{4t^2}\right) \\ &= \frac{t^2}{4} - t + \frac{3}{4t^2} \end{aligned}$$

We see that the coefficient of the term t in the quotient is 0. Now b can be found.

$$\begin{aligned} b &= (0) - (1) \\ &= -1 \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= -1 + \frac{t}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-1}{\frac{1}{2}} - 1\right) &&= -\frac{3}{2} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-1}{\frac{1}{2}} - 1\right) &&= \frac{1}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{t^4 - 4t^3 + 3}{4t^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-2	$-1+\frac{t}{2}$	$-\frac{3}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\ &= \frac{1}{2} - \left(-\frac{1}{2}\right) \\ &= 1 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{t-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{t-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= -\frac{1}{2t} + (-)\left(-1+\frac{t}{2}\right) \\ &= -\frac{1}{2t} + 1 - \frac{t}{2} \\ &= -\frac{(t-1)^2}{2t} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(t)$ of degree $d = 1$ to solve the ode. The polynomial $p(t)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(t) = t + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{2t} + 1 - \frac{t}{2}\right)(1) + \left(\left(\frac{1}{2t^2} - \frac{1}{2}\right) + \left(-\frac{1}{2t} + 1 - \frac{t}{2}\right)^2 - \left(\frac{t^4 - 4t^3 + 3}{4t^2}\right) \right) = 0$$

$$\frac{(a_0+1)(t-1)}{t} = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = -1\}$$

Substituting these coefficients in $p(t)$ in eq. (2A) results in

$$p(t) = t - 1$$

Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(t) &= pe^{\int \omega\, dt} \\
&= (t-1)\, e^{\int \left(-\frac{1}{2t}+1-\frac{t}{2}\right)dt} \\
&= (t-1)\, e^{-\frac{t^2}{4}+t-\frac{\ln(t)}{2}} \\
&= \frac{(t-1)\, e^{-\frac{t(t-4)}{4}}}{\sqrt{t}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dt} \\
&= z_1 e^{-\int \frac{1}{2}\frac{t^2-1}{t}\, dt} \\
&= z_1 e^{-\frac{t^2}{4}+\frac{\ln(t)}{2}} \\
&= z_1 \left(\sqrt{t}\, e^{-\frac{t^2}{4}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = (t-1)\, e^{-\frac{t(t-2)}{2}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dt}}{y_1^2}\, dt
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{t^2-1}{t}\, dt}}{(y_1)^2}\, dt \\
&= y_1 \int \frac{e^{-\frac{t^2}{2}+\ln(t)}}{(y_1)^2}\, dt \\
&= y_1 \left(\int \frac{e^{-\frac{t^2}{2}+\ln(t)} e^{t(t-2)}}{(t-1)^2} dt \right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left((t-1)\, e^{-\frac{t(t-2)}{2}} \right) + c_2 \left((t-1)\, e^{-\frac{t(t-2)}{2}} \left(\int \frac{e^{-\frac{t^2}{2}+\ln(t)} e^{t(t-2)}}{(t-1)^2} dt \right) \right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$t\left(\frac{d^2}{dt^2}y(t)\right)+(t^2-1)\left(\frac{d}{dt}y(t)\right)+t^2y(t)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dt^2}y(t)$

- Isolate 2nd derivative

  $\frac{d^2}{dt^2}y(t)=-ty(t)-\frac{(t^2-1)\left(\frac{d}{dt}y(t)\right)}{t}$

- Group terms with $y(t)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d^2}{dt^2}y(t)+\frac{(t^2-1)\left(\frac{d}{dt}y(t)\right)}{t}+ty(t)=0$

☐ Check to see if $t_0=0$ is a regular singular point

  - Define functions

    $\left[P_2(t)=\frac{t^2-1}{t}, P_3(t)=t\right]$

  - $t\cdot P_2(t)$ is analytic at $t=0$

    $\left.(t\cdot P_2(t))\right|_{t=0}=-1$

  - $t^2\cdot P_3(t)$ is analytic at $t=0$

    $\left.(t^2\cdot P_3(t))\right|_{t=0}=0$

  - $t=0$is a regular singular point

  Check to see if $t_0=0$ is a regular singular point

  $t_0=0$

- Multiply by denominators

  $t\left(\frac{d^2}{dt^2}y(t)\right)+(t^2-1)\left(\frac{d}{dt}y(t)\right)+t^2y(t)=0$

- Assume series solution for $y(t)$

  $y(t)=\sum_{k=0}^{\infty}a_k t^{k+r}$

☐ Rewrite ODE with series expansions

  - Convert $t^2\cdot y(t)$ to series expansion

    $t^2\cdot y(t)=\sum_{k=0}^{\infty}a_k t^{k+r+2}$

  - Shift index using $k->k-2$

    $t^2\cdot y(t)=\sum_{k=2}^{\infty}a_{k-2}t^{k+r}$

  - Convert $t^m\cdot\left(\frac{d}{dt}y(t)\right)$ to series expansion for $m=0..2$

    $t^m\cdot\left(\frac{d}{dt}y(t)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,t^{k+r-1+m}$

  - Shift index using $k->k+1-m$

    $t^m\cdot\left(\frac{d}{dt}y(t)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,t^{k+r}$

  - Convert $t\cdot\left(\frac{d^2}{dt^2}y(t)\right)$ to series expansion

    $t\cdot\left(\frac{d^2}{dt^2}y(t)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,t^{k+r-1}$

  - Shift index using $k->k+1$

    $t\cdot\left(\frac{d^2}{dt^2}y(t)\right)=\sum_{k=-1}^{\infty}a_{k+1}(k+1+r)\,(k+r)\,t^{k+r}$

  Rewrite ODE with series expansions

$$a_0 r(-2+r)\, t^{-1+r} + a_1(1+r)\,(-1+r)\, t^r + (a_2(2+r)\, r + a_0 r)\, t^{1+r} + \left(\sum_{k=2}^{\infty} (a_{k+1}(k+1+r)\,(k+$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $r(-2+r) = 0$
- Values of r that satisfy the indicial equation
  $r \in \{0, 2\}$
- The coefficients of each power of t must be 0
  $[a_1(1+r)\,(-1+r) = 0, a_2(2+r)\, r + a_0 r = 0]$
- Solve for the dependent coefficient(s)
  $\left\{a_1 = 0, a_2 = -\frac{a_0}{2+r}\right\}$
- Each term in the series must be 0, giving the recursion relation
  $a_{k+1}(k+1+r)\,(k+r-1) + a_{k-1}(k+r-1) + a_{k-2} = 0$
- Shift index using $k- >k+2$
  $a_{k+3}(k+3+r)\,(k+1+r) + a_{k+1}(k+1+r) + a_k = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+3} = -\frac{k a_{k+1} + r a_{k+1} + a_k + a_{k+1}}{(k+3+r)(k+1+r)}$
- Recursion relation for $r = 0$
  $a_{k+3} = -\frac{k a_{k+1} + a_k + a_{k+1}}{(k+3)(k+1)}$
- Solution for $r = 0$
  $\left[y(t) = \sum_{k=0}^{\infty} a_k t^k, a_{k+3} = -\frac{k a_{k+1} + a_k + a_{k+1}}{(k+3)(k+1)}, a_1 = 0, a_2 = -\frac{a_0}{2}\right]$
- Recursion relation for $r = 2$
  $a_{k+3} = -\frac{k a_{k+1} + a_k + 3a_{k+1}}{(k+5)(k+3)}$
- Solution for $r = 2$
  $\left[y(t) = \sum_{k=0}^{\infty} a_k t^{k+2}, a_{k+3} = -\frac{k a_{k+1} + a_k + 3a_{k+1}}{(k+5)(k+3)}, a_1 = 0, a_2 = -\frac{a_0}{4}\right]$
- Combine solutions and rename parameters
  $\left[y(t) = \left(\sum_{k=0}^{\infty} a_k t^k\right) + \left(\sum_{k=0}^{\infty} b_k t^{k+2}\right), a_{k+3} = -\frac{k a_{k+1} + a_k + a_{k+1}}{(k+3)(k+1)}, a_1 = 0, a_2 = -\frac{a_0}{2}, b_{k+3} = -\frac{k b_{k+1} + b_k +}{(5+k)(k}\right.$

Solve

$$t^2y'' - t(t+2)\,y' + (t+2)\,y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.071 (sec)

Writing the ode as

$$t^2y'' + \left(-t^2-2t\right)y' + (t+2)\,y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= t^2 \\ B &= -t^2-2t \\ C &= t+2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(t) = ye^{\int \frac{B}{2A}\,dt}$$

Then (2) becomes

$$z''(t) = rz(t) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(t) = \frac{z(t)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(t)$ then y is found using the inverse transformation

$$y = z(t)\, e^{-\int \frac{B}{2A}\, dt}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.21: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{1}{4}$ is not a function of t, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(t) = \mathrm{e}^{-\frac{t}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dt} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-t^2-2t}{t^2}\, dt} \\ &= z_1 e^{\frac{t}{2}+\ln(t)} \\ &= z_1 \left(t\, \mathrm{e}^{\frac{t}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = t$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dt}}{y_1^2}\, dt$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-t^2-2t}{t^2} dt}}{(y_1)^2} dt \\ &= y_1 \int \frac{e^{t+2\ln(t)}}{(y_1)^2} dt \\ &= y_1 \left(\frac{e^{t+2\ln(t)}}{t^2} \right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(t) + c_2 \left(t \left(\frac{e^{t+2\ln(t)}}{t^2} \right) \right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$t^2 \left(\frac{d^2}{dt^2} y(t) \right) - t(t+2) \left(\frac{d}{dt} y(t) \right) + (t+2)\, y(t) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dt^2} y(t)$

- Isolate 2nd derivative

  $\frac{d^2}{dt^2} y(t) = -\frac{(t+2)y(t)}{t^2} + \frac{(t+2)\left(\frac{d}{dt} y(t)\right)}{t}$

- Group terms with $y(t)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dt^2} y(t) - \frac{(t+2)\left(\frac{d}{dt} y(t)\right)}{t} + \frac{(t+2)y(t)}{t^2} = 0$

☐ Check to see if $t_0 = 0$ is a regular singular point

- ○ Define functions

  $\left[P_2(t) = -\frac{t+2}{t}, P_3(t) = \frac{t+2}{t^2} \right]$

- ○ $t \cdot P_2(t)$ is analytic at $t = 0$

  $\left(t \cdot P_2(t)\right)\Big|_{t=0} = -2$

- ○ $t^2 \cdot P_3(t)$ is analytic at $t = 0$

  $\left(t^2 \cdot P_3(t)\right)\Big|_{t=0} = 2$

- ○ $t = 0$is a regular singular point

  Check to see if $t_0 = 0$ is a regular singular point

  $t_0 = 0$

- Multiply by denominators

  $t^2 \left(\frac{d^2}{dt^2} y(t) \right) - t(t+2) \left(\frac{d}{dt} y(t) \right) + (t+2)\, y(t) = 0$

- Assume series solution for $y(t)$

  $y(t) = \sum_{k=0}^{\infty} a_k t^{k+r}$

☐ Rewrite ODE with series expansions

- ○ Convert $t^m \cdot y(t)$ to series expansion for $m = 0..1$

  $t^m \cdot y(t) = \sum_{k=0}^{\infty} a_k t^{k+r+m}$

- Shift index using $k->k-m$

  $t^m \cdot y(t) = \sum_{k=m}^{\infty} a_{k-m} t^{k+r}$

- Convert $t^m \cdot \left(\frac{d}{dt}y(t)\right)$ to series expansion for $m = 1..2$

  $t^m \cdot \left(\frac{d}{dt}y(t)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, t^{k+r-1+m}$

- Shift index using $k->k+1-m$

  $t^m \cdot \left(\frac{d}{dt}y(t)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, t^{k+r}$

- Convert $t^2 \cdot \left(\frac{d^2}{dt^2}y(t)\right)$ to series expansion

  $t^2 \cdot \left(\frac{d^2}{dt^2}y(t)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, t^{k+r}$

  Rewrite ODE with series expansions

  $a_0(-1+r)(-2+r)\, t^r + \left(\sum_{k=1}^{\infty} \left(a_k(k+r-1)(k+r-2) - a_{k-1}(k+r-2)\right) t^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-1+r)(-2+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{1, 2\}$

- Each term in the series must be 0, giving the recursion relation

  $(k+r-2)\left(a_k(k+r-1) - a_{k-1}\right) = 0$

- Shift index using $k->k+1$

  $(k+r-1)\left(a_{k+1}(k+r) - a_k\right) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+1} = \frac{a_k}{k+r}$

- Recursion relation for $r = 1$

  $a_{k+1} = \frac{a_k}{k+1}$

- Solution for $r = 1$

  $\left[y(t) = \sum_{k=0}^{\infty} a_k t^{k+1}, a_{k+1} = \frac{a_k}{k+1}\right]$

- Recursion relation for $r = 2$

  $a_{k+1} = \frac{a_k}{k+2}$

- Solution for $r = 2$

  $\left[y(t) = \sum_{k=0}^{\infty} a_k t^{k+2}, a_{k+1} = \frac{a_k}{k+2}\right]$

- Combine solutions and rename parameters

  $\left[y(t) = \left(\sum_{k=0}^{\infty} a_k t^{k+1}\right) + \left(\sum_{k=0}^{\infty} b_k t^{k+2}\right), a_{k+1} = \frac{a_k}{k+1}, b_{k+1} = \frac{b_k}{k+2}\right]$

2.1.14 Problem 14

Internal problem ID [9186]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 14
Date solved : `Monday, January 27, 2025 at 05:51:51 PM`
CAS classification : `[_Laguerre]`

Solve

$$ty'' - (1+t)\,y' + y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.220 (sec)

Writing the ode as

$$ty'' + (-1-t)\,y' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= t \\ B &= -1-t \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(t) = ye^{\int \frac{B}{2A}\,dt}$$

Then (2) becomes

$$z''(t) = rz(t) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{t^2 - 2t + 3}{4t^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= t^2 - 2t + 3 \\ t &= 4t^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(t) = \left(\frac{t^2 - 2t + 3}{4t^2}\right) z(t) \tag{7}$$

Equation (7) is now solved. After finding $z(t)$ then y is found using the inverse transformation

$$y = z(t)\, e^{-\int \frac{B}{2A}\, dt}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.23: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4t^2$. There is a pole at $t = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} + \frac{3}{4t^2} - \frac{1}{2t}$$

For the pole at $t = 0$ let b be the coefficient of $\frac{1}{t^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving t^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i t^i \\ &= \sum_{i=0}^{0} a_i t^i \end{aligned} \tag{8}$$

Let a be the coefficient of $t^v = t^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} - \frac{1}{2t} + \frac{1}{2t^2} + \frac{1}{2t^3} + \frac{1}{4t^4} - \frac{1}{4t^5} - \frac{3}{4t^6} - \frac{3}{4t^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i t^i \\ &= \frac{1}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $t^{v-1} = t^{-1} = \frac{1}{t}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{t}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{t}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{t}$ in r will be the coefficient in R of the term in t of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{t^2 - 2t + 3}{4t^2} \\ &= Q + \frac{R}{4t^2} \\ &= \left(\frac{1}{4}\right) + \left(\frac{-2t + 3}{4t^2}\right) \\ &= \frac{1}{4} + \frac{-2t + 3}{4t^2} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term t in the remainder R is -2. Dividing this by leading coefficient in t which is 4 gives $-\frac{1}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{1}{2}\right) - (0) \\ &= -\frac{1}{2} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &&= -\frac{1}{2} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &&= \frac{1}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{t^2 - 2t + 3}{4t^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	$-\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = -\frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^+ - \left(\alpha_{c_1}^-\right) \\ &= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{t-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{t-c_1} \right) + (+)[\sqrt{r}]_\infty \\ &= -\frac{1}{2t} + \left(\frac{1}{2}\right) \\ &= \frac{1}{2} - \frac{1}{2t} \\ &= \frac{t-1}{2t} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(t)$ of degree $d = 0$ to solve the ode. The polynomial $p(t)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(t) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(\frac{1}{2} - \frac{1}{2t}\right)(0) + \left(\left(\frac{1}{2t^2}\right) + \left(\frac{1}{2} - \frac{1}{2t}\right)^2 - \left(\frac{t^2-2t+3}{4t^2}\right)\right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(t) &= p e^{\int \omega \, dt} \\ &= e^{\int \left(\frac{1}{2} - \frac{1}{2t}\right) dt} \\ &= \frac{e^{\frac{t}{2}}}{\sqrt{t}} \end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dt} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-1-t}{t}\,dt} \\
&= z_1 e^{\frac{t}{2}+\frac{\ln(t)}{2}} \\
&= z_1\left(\sqrt{t}\,\mathrm{e}^{\frac{t}{2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^t
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dt}}{y_1^2}\,dt
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-1-t}{t}\,dt}}{(y_1)^2}\,dt \\
&= y_1 \int \frac{e^{t+\ln(t)}}{(y_1)^2}\,dt \\
&= y_1\left(-\frac{(1+t)\,\mathrm{e}^{t+\ln(t)}\mathrm{e}^{-2t}}{t}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^t\right) + c_2\left(\mathrm{e}^t\left(-\frac{(1+t)\,\mathrm{e}^{t+\ln(t)}\mathrm{e}^{-2t}}{t}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$t\left(\frac{d^2}{dt^2}y(t)\right) - (t+1)\left(\frac{d}{dt}y(t)\right) + y(t) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dt^2}y(t)$
- Isolate 2nd derivative

  $\frac{d^2}{dt^2}y(t) = -\frac{y(t)}{t} + \frac{(t+1)\left(\frac{d}{dt}y(t)\right)}{t}$
- Group terms with $y(t)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d^2}{dt^2}y(t) - \frac{(t+1)\left(\frac{d}{dt}y(t)\right)}{t} + \frac{y(t)}{t} = 0$

☐ Check to see if $t_0 = 0$ is a regular singular point

- Define functions

  $\left[P_2(t) = -\frac{t+1}{t}, P_3(t) = \frac{1}{t}\right]$
- $t \cdot P_2(t)$ is analytic at $t = 0$

$(t \cdot P_2(t))\Big|_{t=0} = -1$

- $t^2 \cdot P_3(t)$ is analytic at $t = 0$

  $(t^2 \cdot P_3(t))\Big|_{t=0} = 0$

- $t = 0$is a regular singular point

  Check to see if $t_0 = 0$ is a regular singular point

  $t_0 = 0$

- Multiply by denominators

  $t\left(\frac{d^2}{dt^2}y(t)\right) + (-t-1)\left(\frac{d}{dt}y(t)\right) + y(t) = 0$

- Assume series solution for $y(t)$

  $y(t) = \sum_{k=0}^{\infty} a_k t^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $t^m \cdot \left(\frac{d}{dt}y(t)\right)$ to series expansion for $m = 0..1$

  $t^m \cdot \left(\frac{d}{dt}y(t)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, t^{k+r-1+m}$

- Shift index using $k- >k+1-m$

  $t^m \cdot \left(\frac{d}{dt}y(t)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, t^{k+r}$

- Convert $t \cdot \left(\frac{d^2}{dt^2}y(t)\right)$ to series expansion

  $t \cdot \left(\frac{d^2}{dt^2}y(t)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, t^{k+r-1}$

- Shift index using $k- >k+1$

  $t \cdot \left(\frac{d^2}{dt^2}y(t)\right) = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)(k+r)\, t^{k+r}$

  Rewrite ODE with series expansions

  $a_0 r(-2+r)\, t^{-1+r} + \left(\sum_{k=0}^{\infty} \left(a_{k+1}(k+1+r)(k+r-1) - a_k(k+r-1)\right) t^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r(-2+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{0, 2\}$

- Each term in the series must be 0, giving the recursion relation

  $(k+r-1)\left(a_{k+1}(k+1+r) - a_k\right) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+1} = \frac{a_k}{k+1+r}$

- Recursion relation for $r = 0$

  $a_{k+1} = \frac{a_k}{k+1}$

- Solution for $r = 0$

  $\left[y(t) = \sum_{k=0}^{\infty} a_k t^k, a_{k+1} = \frac{a_k}{k+1}\right]$

- Recursion relation for $r = 2$

  $a_{k+1} = \frac{a_k}{k+3}$

- Solution for $r = 2$

  $\left[y(t) = \sum_{k=0}^{\infty} a_k t^{k+2}, a_{k+1} = \frac{a_k}{k+3}\right]$

- Combine solutions and rename parameters

$$\left[y(t) = \left(\sum_{k=0}^{\infty} a_k t^k\right) + \left(\sum_{k=0}^{\infty} b_k t^{k+2}\right), a_{k+1} = \frac{a_k}{k+1}, b_{k+1} = \frac{b_k}{k+3}\right]$$

```

$$y(t) \to \sqrt{t} \exp\left(\frac{1}{2}\left(2\int_1^t \frac{K[1]-1}{2K[1]} dK[1] + t + 1\right)\right)\left(c_2 \int_1^t \exp\left(-2\int_1^{K[2]} \frac{K[1]-1}{2K[1]} dK[1]\right) dK[2] + c_1\right)$$

2.1.15 Problem 15

Internal problem ID [9187]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 15
Date solved : `Monday, January 27, 2025 at 05:51:52 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$(1-t)\,y''+ty'-y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.232 (sec)

Writing the ode as

$$(1-t)\,y''+ty'-y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=1-t\\B&=t\\C&=-1\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(t)=ye^{\int \frac{B}{2A}\,dt}$$

Then (2) becomes

$$z''(t)=rz(t) \tag{4}$$

Where r is given by

$$\begin{aligned}r&=\frac{s}{t} \\ &=\frac{2AB'-2BA'+B^2-4AC}{4A^2}\end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{t^2-4t+6}{4\,(-1+t)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned}s&=t^2-4t+6\\t&=4(-1+t)^2\end{aligned}$$

Therefore eq. (4) becomes

$$z''(t)=\left(\frac{t^2-4t+6}{4\,(-1+t)^2}\right)z(t) \tag{7}$$

Equation (7) is now solved. After finding $z(t)$ then y is found using the inverse transformation

$$y = z(t)\, e^{-\int \frac{B}{2A}\, dt}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.25: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(-1+t)^2$. There is a pole at $t = 1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} + \frac{3}{4\,(-1+t)^2} - \frac{1}{2\,(-1+t)}$$

For the pole at $t = 1$ let b be the coefficient of $\frac{1}{(-1+t)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving t^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i t^i \\ &= \sum_{i=0}^{0} a_i t^i \end{aligned} \tag{8}$$

Let a be the coefficient of $t^v = t^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} - \frac{1}{2t} + \frac{1}{t^3} + \frac{11}{4t^4} + \frac{21}{4t^5} + \frac{15}{2t^6} + \frac{6}{t^7} - \frac{117}{16t^8} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i t^i \\ &= \frac{1}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $t^{v-1} = t^{-1} = \frac{1}{t}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{t}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{t}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{t}$ in r will be the coefficient in R of the term in t of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{t^2 - 4t + 6}{4t^2 - 8t + 4} \\ &= Q + \frac{R}{4t^2 - 8t + 4} \\ &= \left(\frac{1}{4}\right) + \left(\frac{-2t + 5}{4t^2 - 8t + 4}\right) \\ &= \frac{1}{4} + \frac{-2t + 5}{4t^2 - 8t + 4} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term t in the remainder R is -2. Dividing this by leading coefficient in t which is 4 gives $-\frac{1}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{1}{2}\right) - (0) \\ &= -\frac{1}{2} \end{aligned}$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \frac{1}{2} \\
\alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &= -\frac{1}{2} \\
\alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &= \frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{t^2 - 4t + 6}{4\left(-1+t\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
1	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	$-\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = -\frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^-\right) \\
&= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{t-c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

Substituting the above values in the above results in

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{t-c_1} \right) + (+)[\sqrt{r}]_\infty \\
&= -\frac{1}{2\left(-1+t\right)} + \left(\frac{1}{2}\right) \\
&= -\frac{1}{2\left(-1+t\right)} + \frac{1}{2} \\
&= \frac{t-2}{2t-2}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(t)$ of degree $d = 0$ to solve the ode. The polynomial $p(t)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(t) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(-\frac{1}{2(-1+t)}+\frac{1}{2}\right)(0)+\left(\left(\frac{1}{2(-1+t)^{2}}\right)+\left(-\frac{1}{2(-1+t)}+\frac{1}{2}\right)^{2}-\left(\frac{t^{2}-4t+6}{4(-1+t)^{2}}\right)\right)=0$$
$$0=0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z''=rz$ is

$$\begin{aligned}
z_1(t) &= p e^{\int \omega\,dt} \\
&= \mathrm{e}^{\int \left(-\frac{1}{2(-1+t)}+\frac{1}{2}\right)dt} \\
&= \frac{\mathrm{e}^{\frac{t}{2}}}{\sqrt{-1+t}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dt} \\
&= z_1 e^{-\int \frac{1}{2}\frac{t}{1-t}\,dt} \\
&= z_1 e^{\frac{t}{2}+\frac{\ln(-1+t)}{2}} \\
&= z_1\left(\sqrt{-1+t}\,\mathrm{e}^{\frac{t}{2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1=\mathrm{e}^{t}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2=y_1\int \frac{e^{\int -\frac{B}{A}\,dt}}{y_1^2}\,dt$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1\int \frac{e^{\int -\frac{t}{1-t}\,dt}}{(y_1)^2}\,dt \\
&= y_1\int \frac{e^{t+\ln(-1+t)}}{(y_1)^2}\,dt \\
&= y_1\left(-\frac{t\,\mathrm{e}^{t+\ln(-1+t)}\mathrm{e}^{-2t}}{-1+t}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1y_1+c_2y_2 \\
&= c_1\left(\mathrm{e}^{t}\right)+c_2\left(\mathrm{e}^{t}\left(-\frac{t\,\mathrm{e}^{t+\ln(-1+t)}\mathrm{e}^{-2t}}{-1+t}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$(1-t)\left(\frac{d^2}{dt^2}y(t)\right)+t\left(\frac{d}{dt}y(t)\right)-y(t)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dt^2}y(t)$
- Isolate 2nd derivative

  $\frac{d^2}{dt^2}y(t)=-\frac{y(t)}{t-1}+\frac{t\left(\frac{d}{dt}y(t)\right)}{t-1}$
- Group terms with $y(t)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d^2}{dt^2}y(t)-\frac{t\left(\frac{d}{dt}y(t)\right)}{t-1}+\frac{y(t)}{t-1}=0$

□ Check to see if $t_0=1$ is a regular singular point
  - Define functions

    $\left[P_2(t)=-\frac{t}{t-1}, P_3(t)=\frac{1}{t-1}\right]$
  - $(t-1)\cdot P_2(t)$ is analytic at $t=1$

    $\left((t-1)\cdot P_2(t)\right)\bigg|_{t=1}=-1$
  - $(t-1)^2\cdot P_3(t)$ is analytic at $t=1$

    $\left((t-1)^2\cdot P_3(t)\right)\bigg|_{t=1}=0$
  - $t=1$is a regular singular point

  Check to see if $t_0=1$ is a regular singular point

  $t_0=1$

- Multiply by denominators

  $(t-1)\left(\frac{d^2}{dt^2}y(t)\right)-t\left(\frac{d}{dt}y(t)\right)+y(t)=0$
- Change variables using $t=u+1$ so that the regular singular point is at $u=0$

  $u\left(\frac{d^2}{du^2}y(u)\right)+(-u-1)\left(\frac{d}{du}y(u)\right)+y(u)=0$
- Assume series solution for $y(u)$

  $y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

□ Rewrite ODE with series expansions
  - Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$

    $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,u^{k+r-1+m}$
  - Shift index using $k->k+1-m$

    $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,u^{k+r}$
  - Convert $u\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion

    $u\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)(k+r-1)\,u^{k+r-1}$
  - Shift index using $k->k+1$

    $u\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=-1}^{\infty}a_{k+1}(k+1+r)(k+r)\,u^{k+r}$

  Rewrite ODE with series expansions

  $a_0r(-2+r)\,u^{-1+r}+\left(\sum_{k=0}^{\infty}\left(a_{k+1}(k+1+r)(k+r-1)-a_k(k+r-1)\right)u^{k+r}\right)=0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$r(-2+r) = 0$

- Values of r that satisfy the indicial equation
  $r \in \{0, 2\}$
- Each term in the series must be 0, giving the recursion relation
  $(k+r-1)\left(a_{k+1}(k+1+r) - a_k\right) = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+1} = \frac{a_k}{k+1+r}$
- Recursion relation for $r = 0$
  $a_{k+1} = \frac{a_k}{k+1}$
- Solution for $r = 0$
  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+1} = \frac{a_k}{k+1}\right]$
- Revert the change of variables $u = t-1$
  $\left[y(t) = \sum_{k=0}^{\infty} a_k (t-1)^k, a_{k+1} = \frac{a_k}{k+1}\right]$
- Recursion relation for $r = 2$
  $a_{k+1} = \frac{a_k}{k+3}$
- Solution for $r = 2$
  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+2}, a_{k+1} = \frac{a_k}{k+3}\right]$
- Revert the change of variables $u = t-1$
  $\left[y(t) = \sum_{k=0}^{\infty} a_k (t-1)^{k+2}, a_{k+1} = \frac{a_k}{k+3}\right]$
- Combine solutions and rename parameters
  $\left[y(t) = \left(\sum_{k=0}^{\infty} a_k (t-1)^k\right) + \left(\sum_{k=0}^{\infty} b_k (t-1)^{k+2}\right), a_{k+1} = \frac{a_k}{k+1}, b_{k+1} = \frac{b_k}{k+3}\right]$

2.1.16 Problem 16

Internal problem ID [9188]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 16
Date solved : `Monday, January 27, 2025 at 05:51:53 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' + xy' + \left(x^2 - \frac{1}{4}\right)y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.148 (sec)

Writing the ode as

$$x^2y'' + xy' + \left(x^2 - \frac{1}{4}\right)y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= x \\ C &= x^2 - \frac{1}{4} \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.27: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{x}{x^2}\, dx} \\ &= z_1 e^{-\frac{\ln(x)}{2}} \\ &= z_1 \left(\frac{1}{\sqrt{x}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{\cos(x)}{\sqrt{x}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{x}{x^2}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{-\ln(x)}}{(y_1)^2}\,dx \\ &= y_1(\tan(x)) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\frac{\cos(x)}{\sqrt{x}}\right) + c_2\left(\frac{\cos(x)}{\sqrt{x}}(\tan(x))\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve
$x^2\left(\frac{d^2}{dx^2}y(x)\right) + x\left(\frac{d}{dx}y(x)\right) + \left(x^2 - \frac{1}{4}\right)y(x) = 0$

- Highest derivative means the order of the ODE is 2
  $\frac{d^2}{dx^2}y(x)$
- Isolate 2nd derivative
  $\frac{d^2}{dx^2}y(x) = -\frac{(4x^2-1)y(x)}{4x^2} - \frac{\frac{d}{dx}y(x)}{x}$
- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin
  $\frac{d^2}{dx^2}y(x) + \frac{\frac{d}{dx}y(x)}{x} + \frac{(4x^2-1)y(x)}{4x^2} = 0$

☐ Check to see if $x_0 = 0$ is a regular singular point
  - Define functions
    $\left[P_2(x) = \frac{1}{x}, P_3(x) = \frac{4x^2-1}{4x^2}\right]$
  - $x \cdot P_2(x)$ is analytic at $x = 0$
    $\left.(x \cdot P_2(x))\right|_{x=0} = 1$
  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$
    $\left.(x^2 \cdot P_3(x))\right|_{x=0} = -\frac{1}{4}$
  - $x = 0$is a regular singular point
    Check to see if $x_0 = 0$ is a regular singular point
    $x_0 = 0$

- Multiply by denominators
  $4x^2\left(\frac{d^2}{dx^2}y(x)\right) + 4x\left(\frac{d}{dx}y(x)\right) + (4x^2 - 1)y(x) = 0$
- Assume series solution for $y(x)$
  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $x^m \cdot y(x)$ to series expansion for $m = 0..2$

  $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- Shift index using $k- >k - m$

  $x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- Convert $x \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion

  $x \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r}$

- Convert $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

  $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(1+2r)\,(-1+2r)\, x^r + a_1(3+2r)\,(1+2r)\, x^{1+r} + \left(\sum_{k=2}^{\infty} (a_k(2k+2r+1)\,(2k+2r-1) + 4a_{k-2})\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(1+2r)\,(-1+2r) = 0$
- Values of r that satisfy the indicial equation

  $r \in \left\{-\frac{1}{2}, \frac{1}{2}\right\}$
- Each term must be 0

  $a_1(3+2r)\,(1+2r) = 0$
- Solve for the dependent coefficient(s)

  $a_1 = 0$
- Each term in the series must be 0, giving the recursion relation

  $a_k(4k^2 + 8kr + 4r^2 - 1) + 4a_{k-2} = 0$
- Shift index using $k- >k + 2$

  $a_{k+2}\left(4(k+2)^2 + 8(k+2)\, r + 4r^2 - 1\right) + 4a_k = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{4a_k}{4k^2+8kr+4r^2+16k+16r+15}$
- Recursion relation for $r = -\frac{1}{2}$

  $a_{k+2} = -\frac{4a_k}{4k^2+12k+8}$
- Solution for $r = -\frac{1}{2}$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k-\frac{1}{2}}, a_{k+2} = -\frac{4a_k}{4k^2+12k+8}, a_1 = 0\right]$
- Recursion relation for $r = \frac{1}{2}$

  $a_{k+2} = -\frac{4a_k}{4k^2+20k+24}$
- Solution for $r = \frac{1}{2}$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}, a_{k+2} = -\frac{4a_k}{4k^2+20k+24}, a_1 = 0\right]$
- Combine solutions and rename parameters

  $\left[y(x) = \left(\sum_{k=0}^{\infty} a_k x^{k-\frac{1}{2}}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{2}}\right), a_{k+2} = -\frac{4a_k}{4k^2+12k+8}, a_1 = 0, b_{k+2} = -\frac{4b_k}{4k^2+20k+24}, b_1 = 0\right]$

2.1.17 Problem 17

Internal problem ID [9189]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 17
Date solved : `Monday, January 27, 2025 at 05:51:53 PM`
CAS classification : `[_Laguerre]`

Solve

$$
ty'' - (1+t)\,y' + y = 0
$$

Solved as second order ode using Kovacic algorithm

Time used: 0.229 (sec)

Writing the ode as

$$
\begin{align*}
ty'' + (-1-t)\,y' + y &= 0 \tag{1}\\
Ay'' + By' + Cy &= 0 \tag{2}
\end{align*}
$$

Comparing (1) and (2) shows that

$$
\begin{align*}
A &= t \\
B &= -1-t \tag{3}\\
C &= 1
\end{align*}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(t) = ye^{\int \frac{B}{2A}\,dt}
$$

Then (2) becomes

$$
z''(t) = rz(t) \tag{4}
$$

Where r is given by

$$
\begin{align*}
r &= \frac{s}{t} \tag{5}\\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{align*}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{t^2-2t+3}{4t^2} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{align*}
s &= t^2-2t+3\\
t &= 4t^2
\end{align*}
$$

Therefore eq. (4) becomes

$$
z''(t) = \left(\frac{t^2-2t+3}{4t^2}\right) z(t) \tag{7}
$$

Equation (7) is now solved. After finding $z(t)$ then y is found using the inverse transformation

$$y = z(t)\, e^{-\int \frac{B}{2A}\, dt}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.29: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4t^2$. There is a pole at $t = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} + \frac{3}{4t^2} - \frac{1}{2t}$$

For the pole at $t = 0$ let b be the coefficient of $\frac{1}{t^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving t^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i t^i \\ &= \sum_{i=0}^{0} a_i t^i \end{aligned} \tag{8}$$

Let a be the coefficient of $t^v = t^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} - \frac{1}{2t} + \frac{1}{2t^2} + \frac{1}{2t^3} + \frac{1}{4t^4} - \frac{1}{4t^5} - \frac{3}{4t^6} - \frac{3}{4t^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i t^i \\ &= \frac{1}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $t^{v-1} = t^{-1} = \frac{1}{t}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{t}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{t}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{t}$ in r will be the coefficient in R of the term in t of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{t^2 - 2t + 3}{4t^2} \\ &= Q + \frac{R}{4t^2} \\ &= \left(\frac{1}{4}\right) + \left(\frac{-2t + 3}{4t^2}\right) \\ &= \frac{1}{4} + \frac{-2t + 3}{4t^2} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term t in the remainder R is -2. Dividing this by leading coefficient in t which is 4 gives $-\frac{1}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{1}{2}\right) - (0) \\ &= -\frac{1}{2} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &&= -\frac{1}{2} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &&= \frac{1}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{t^2 - 2t + 3}{4t^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	$-\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = -\frac{1}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^-\right) \\
&= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{t-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{t-c_1} \right) + (+)[\sqrt{r}]_\infty \\
&= -\frac{1}{2t} + \left(\frac{1}{2}\right) \\
&= \frac{1}{2} - \frac{1}{2t} \\
&= \frac{t-1}{2t}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(t)$ of degree $d = 0$ to solve the ode. The polynomial $p(t)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(t) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned}
(0) + 2\left(\frac{1}{2} - \frac{1}{2t}\right)(0) + \left(\left(\frac{1}{2t^2}\right) + \left(\frac{1}{2} - \frac{1}{2t}\right)^2 - \left(\frac{t^2 - 2t + 3}{4t^2}\right) \right) &= 0 \\
0 &= 0
\end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(t) &= p e^{\int \omega \, dt} \\
&= e^{\int \left(\frac{1}{2} - \frac{1}{2t}\right) dt} \\
&= \frac{e^{\frac{t}{2}}}{\sqrt{t}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dt} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-1-t}{t}\,dt} \\ &= z_1 e^{\frac{t}{2}+\frac{\ln(t)}{2}} \\ &= z_1\left(\sqrt{t}\,\mathrm{e}^{\frac{t}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{t}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dt}}{y_1^2}\,dt$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-1-t}{t}\,dt}}{(y_1)^2}\,dt \\ &= y_1 \int \frac{e^{t+\ln(t)}}{(y_1)^2}\,dt \\ &= y_1\left(-\frac{(1+t)\,\mathrm{e}^{t+\ln(t)}\mathrm{e}^{-2t}}{t}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\mathrm{e}^{t}\right) + c_2\left(\mathrm{e}^{t}\left(-\frac{(1+t)\,\mathrm{e}^{t+\ln(t)}\mathrm{e}^{-2t}}{t}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$t\left(\frac{d^2}{dt^2}y(t)\right) - (t+1)\left(\frac{d}{dt}y(t)\right) + y(t) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dt^2}y(t)$

- Isolate 2nd derivative

  $\frac{d^2}{dt^2}y(t) = -\frac{y(t)}{t} + \frac{(t+1)\left(\frac{d}{dt}y(t)\right)}{t}$

- Group terms with $y(t)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d^2}{dt^2}y(t) - \frac{(t+1)\left(\frac{d}{dt}y(t)\right)}{t} + \frac{y(t)}{t} = 0$

- ☐ Check to see if $t_0 = 0$ is a regular singular point
  - ◦ Define functions

    $\left[P_2(t) = -\frac{t+1}{t}, P_3(t) = \frac{1}{t}\right]$
  - ◦ $t \cdot P_2(t)$ is analytic at $t = 0$

$\left(t \cdot P_2(t)\right)\bigg|_{t=0} = -1$

- ◦ $t^2 \cdot P_3(t)$ is analytic at $t = 0$

  $\left(t^2 \cdot P_3(t)\right)\bigg|_{t=0} = 0$

- ◦ $t = 0$is a regular singular point

  Check to see if $t_0 = 0$ is a regular singular point

  $t_0 = 0$

- Multiply by denominators

  $t\left(\frac{d^2}{dt^2}y(t)\right) + (-t-1)\left(\frac{d}{dt}y(t)\right) + y(t) = 0$

- Assume series solution for $y(t)$

  $y(t) = \sum_{k=0}^{\infty} a_k t^{k+r}$

- □ Rewrite ODE with series expansions

  - ◦ Convert $t^m \cdot \left(\frac{d}{dt}y(t)\right)$ to series expansion for $m = 0..1$

    $t^m \cdot \left(\frac{d}{dt}y(t)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, t^{k+r-1+m}$

  - ◦ Shift index using $k- >k+1-m$

    $t^m \cdot \left(\frac{d}{dt}y(t)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, t^{k+r}$

  - ◦ Convert $t \cdot \left(\frac{d^2}{dt^2}y(t)\right)$ to series expansion

    $t \cdot \left(\frac{d^2}{dt^2}y(t)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, t^{k+r-1}$

  - ◦ Shift index using $k- >k+1$

    $t \cdot \left(\frac{d^2}{dt^2}y(t)\right) = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)(k+r)\, t^{k+r}$

  Rewrite ODE with series expansions

  $a_0 r(-2+r)\, t^{-1+r} + \left(\sum_{k=0}^{\infty} \left(a_{k+1}(k+1+r)(k+r-1) - a_k(k+r-1)\right) t^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r(-2+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{0, 2\}$

- Each term in the series must be 0, giving the recursion relation

  $(k+r-1)\left(a_{k+1}(k+1+r) - a_k\right) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+1} = \frac{a_k}{k+1+r}$

- Recursion relation for $r = 0$

  $a_{k+1} = \frac{a_k}{k+1}$

- Solution for $r = 0$

  $\left[y(t) = \sum_{k=0}^{\infty} a_k t^k, a_{k+1} = \frac{a_k}{k+1}\right]$

- Recursion relation for $r = 2$

  $a_{k+1} = \frac{a_k}{k+3}$

- Solution for $r = 2$

  $\left[y(t) = \sum_{k=0}^{\infty} a_k t^{k+2}, a_{k+1} = \frac{a_k}{k+3}\right]$

- Combine solutions and rename parameters

$$\left[y(t)=\left(\sum_{k=0}^{\infty} a_k t^k\right)+\left(\sum_{k=0}^{\infty} b_k t^{k+2}\right), a_{k+1}=\frac{a_k}{k+1}, b_{k+1}=\frac{b_k}{k+3}\right]$$

2.1.18 Problem 18

Internal problem ID [9190]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 18
Date solved : `Monday, January 27, 2025 at 05:51:54 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$(1-t)\,y''+ty'-y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.223 (sec)

Writing the ode as

$$(1-t)\,y''+ty'-y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=1-t\\B&=t\\C&=-1\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(t)=ye^{\int \frac{B}{2A}\,dt}$$

Then (2) becomes

$$z''(t)=rz(t) \tag{4}$$

Where r is given by

$$\begin{aligned}r&=\frac{s}{t}\\&=\frac{2AB'-2BA'+B^2-4AC}{4A^2}\end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{t^2-4t+6}{4\left(-1+t\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned}s&=t^2-4t+6\\t&=4(-1+t)^2\end{aligned}$$

Therefore eq. (4) becomes

$$z''(t)=\left(\frac{t^2-4t+6}{4\left(-1+t\right)^2}\right)z(t) \tag{7}$$

Equation (7) is now solved. After finding $z(t)$ then y is found using the inverse transformation

$$y = z(t)\, e^{-\int \frac{B}{2A}\, dt}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.31: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(-1+t)^2$. There is a pole at $t = 1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} + \frac{3}{4\,(-1+t)^2} - \frac{1}{2\,(-1+t)}$$

For the pole at $t = 1$ let b be the coefficient of $\frac{1}{(-1+t)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving t^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i t^i \\ &= \sum_{i=0}^{0} a_i t^i \end{aligned} \tag{8}$$

Let a be the coefficient of $t^v = t^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} - \frac{1}{2t} + \frac{1}{t^3} + \frac{11}{4t^4} + \frac{21}{4t^5} + \frac{15}{2t^6} + \frac{6}{t^7} - \frac{117}{16t^8} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i t^i \\ &= \frac{1}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $t^{v-1} = t^{-1} = \frac{1}{t}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{t}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{t}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{t}$ in r will be the coefficient in R of the term in t of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{t^2 - 4t + 6}{4t^2 - 8t + 4} \\ &= Q + \frac{R}{4t^2 - 8t + 4} \\ &= \left(\frac{1}{4}\right) + \left(\frac{-2t + 5}{4t^2 - 8t + 4}\right) \\ &= \frac{1}{4} + \frac{-2t + 5}{4t^2 - 8t + 4} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term t in the remainder R is -2. Dividing this by leading coefficient in t which is 4 gives $-\frac{1}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{1}{2}\right) - (0) \\ &= -\frac{1}{2} \end{aligned}$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \frac{1}{2} \\
\alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &= -\frac{1}{2} \\
\alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &= \frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{t^2 - 4t + 6}{4(-1+t)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
1	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	$-\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = -\frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^+ - (\alpha_{c_1}^-) \\
&= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{t-c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

Substituting the above values in the above results in

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{t-c_1} \right) + (+)[\sqrt{r}]_\infty \\
&= -\frac{1}{2(-1+t)} + \left(\frac{1}{2}\right) \\
&= -\frac{1}{2(-1+t)} + \frac{1}{2} \\
&= \frac{t-2}{2t-2}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(t)$ of degree $d = 0$ to solve the ode. The polynomial $p(t)$ needs to satisfy the equation

$$
p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}
$$

Let

$$
p(t) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{2(-1+t)} + \frac{1}{2}\right)(0) + \left(\left(\frac{1}{2(-1+t)^2}\right) + \left(-\frac{1}{2(-1+t)} + \frac{1}{2}\right)^2 - \left(\frac{t^2-4t+6}{4(-1+t)^2}\right)\right) = 0$$
$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(t) &= pe^{\int \omega\, dt} \\ &= \mathrm{e}^{\int \left(-\frac{1}{2(-1+t)} + \frac{1}{2}\right) dt} \\ &= \frac{\mathrm{e}^{\frac{t}{2}}}{\sqrt{-1+t}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dt} \\ &= z_1 e^{-\int \frac{1}{2}\frac{t}{1-t}\, dt} \\ &= z_1 e^{\frac{t}{2} + \frac{\ln(-1+t)}{2}} \\ &= z_1 \left(\sqrt{-1+t}\, \mathrm{e}^{\frac{t}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^t$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dt}}{y_1^2}\, dt$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{t}{1-t}\, dt}}{(y_1)^2}\, dt \\ &= y_1 \int \frac{e^{t+\ln(-1+t)}}{(y_1)^2}\, dt \\ &= y_1 \left(-\frac{t\,\mathrm{e}^{t+\ln(-1+t)}\mathrm{e}^{-2t}}{-1+t}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\mathrm{e}^t\right) + c_2\left(\mathrm{e}^t\left(-\frac{t\,\mathrm{e}^{t+\ln(-1+t)}\mathrm{e}^{-2t}}{-1+t}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$(1-t)\left(\frac{d^2}{dt^2}y(t)\right)+t\left(\frac{d}{dt}y(t)\right)-y(t)=0$

- Highest derivative means the order of the ODE is 2

$\frac{d^2}{dt^2}y(t)$

- Isolate 2nd derivative

$\frac{d^2}{dt^2}y(t)=-\frac{y(t)}{t-1}+\frac{t\left(\frac{d}{dt}y(t)\right)}{t-1}$

- Group terms with $y(t)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$\frac{d^2}{dt^2}y(t)-\frac{t\left(\frac{d}{dt}y(t)\right)}{t-1}+\frac{y(t)}{t-1}=0$

□ Check to see if $t_0=1$ is a regular singular point

  ◦ Define functions

  $\left[P_2(t)=-\frac{t}{t-1}, P_3(t)=\frac{1}{t-1}\right]$

  ◦ $(t-1)\cdot P_2(t)$ is analytic at $t=1$

  $\left((t-1)\cdot P_2(t)\right)\Big|_{t=1}=-1$

  ◦ $(t-1)^2\cdot P_3(t)$ is analytic at $t=1$

  $\left((t-1)^2\cdot P_3(t)\right)\Big|_{t=1}=0$

  ◦ $t=1$is a regular singular point

  Check to see if $t_0=1$ is a regular singular point

  $t_0=1$

- Multiply by denominators

$(t-1)\left(\frac{d^2}{dt^2}y(t)\right)-t\left(\frac{d}{dt}y(t)\right)+y(t)=0$

- Change variables using $t=u+1$ so that the regular singular point is at $u=0$

$u\left(\frac{d^2}{du^2}y(u)\right)+(-u-1)\left(\frac{d}{du}y(u)\right)+y(u)=0$

- Assume series solution for $y(u)$

$y(u)=\sum_{k=0}^{\infty} a_k u^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$

  $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty} a_k(k+r)\,u^{k+r-1+m}$

  ◦ Shift index using $k->k+1-m$

  $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,u^{k+r}$

  ◦ Convert $u\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion

  $u\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\,u^{k+r-1}$

  ◦ Shift index using $k->k+1$

  $u\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=-1}^{\infty} a_{k+1}(k+1+r)(k+r)\,u^{k+r}$

  Rewrite ODE with series expansions

  $a_0r(-2+r)\,u^{-1+r}+\left(\sum_{k=0}^{\infty}\left(a_{k+1}(k+1+r)(k+r-1)-a_k(k+r-1)\right)u^{k+r}\right)=0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$r(-2+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{0, 2\}$

- Each term in the series must be 0, giving the recursion relation

  $(k+r-1)\left(a_{k+1}(k+1+r) - a_k\right) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+1} = \frac{a_k}{k+1+r}$

- Recursion relation for $r = 0$

  $a_{k+1} = \frac{a_k}{k+1}$

- Solution for $r = 0$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+1} = \frac{a_k}{k+1}\right]$

- Revert the change of variables $u = t-1$

  $\left[y(t) = \sum_{k=0}^{\infty} a_k (t-1)^k, a_{k+1} = \frac{a_k}{k+1}\right]$

- Recursion relation for $r = 2$

  $a_{k+1} = \frac{a_k}{k+3}$

- Solution for $r = 2$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+2}, a_{k+1} = \frac{a_k}{k+3}\right]$

- Revert the change of variables $u = t-1$

  $\left[y(t) = \sum_{k=0}^{\infty} a_k (t-1)^{k+2}, a_{k+1} = \frac{a_k}{k+3}\right]$

- Combine solutions and rename parameters

  $\left[y(t) = \left(\sum_{k=0}^{\infty} a_k (t-1)^k\right) + \left(\sum_{k=0}^{\infty} b_k (t-1)^{k+2}\right), a_{k+1} = \frac{a_k}{k+1}, b_{k+1} = \frac{b_k}{k+3}\right]$

Solve

$$y'' + xy' + 2y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.217 (sec)

Writing the ode as

$$y'' + xy' + 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= x \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 - 6}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2 - 6 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2}{4} - \frac{3}{2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.33: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 2 \\ &= -2 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x}{2} - \frac{3}{2x} - \frac{9}{4x^3} - \frac{27}{4x^5} - \frac{405}{16x^7} - \frac{1701}{16x^9} - \frac{15309}{32x^{11}} - \frac{72171}{32x^{13}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v=1$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= \frac{x}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1}=x^0=1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{x^2}{4}$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v=0$ or not. Since $v=1$ which is not zero, then starting $r=\frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2-6}{4} \\ &= Q + \frac{R}{4} \\ &= \left(\frac{x^2}{4} - \frac{3}{2}\right) + (0) \\ &= \frac{x^2}{4} - \frac{3}{2} \end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is $-\frac{3}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{3}{2}\right) - (0) \\ &= -\frac{3}{2} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{x}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-\frac{3}{2}}{\frac{1}{2}} - 1\right) &= -2 \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-\frac{3}{2}}{\frac{1}{2}} - 1\right) &= 1 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2}{4} - \frac{3}{2}$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-2	$\frac{x}{2}$	-2	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$, and since there are no poles then

$$\begin{aligned} d &= \alpha_\infty^- \\ &= 1 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= (-)[\sqrt{r}]_\infty \\ &= 0 + (-)\left(\frac{x}{2}\right) \\ &= -\frac{x}{2} \\ &= -\frac{x}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(-\frac{x}{2}\right)(1) + \left(\left(-\frac{1}{2}\right) + \left(-\frac{x}{2}\right)^2 - \left(\frac{x^2}{4} - \frac{3}{2}\right)\right) &= 0 \\ a_0 &= 0 \end{aligned}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega\, dx} \\ &= (x)\, e^{\int -\frac{x}{2} dx} \\ &= (x)\, e^{-\frac{x^2}{4}} \\ &= x\, e^{-\frac{x^2}{4}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{x}{1}\, dx} \\ &= z_1 e^{-\frac{x^2}{4}} \\ &= z_1\left(e^{-\frac{x^2}{4}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-\frac{x^2}{2}} x$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{x}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{-\frac{x^2}{2}}}{(y_1)^2}\,dx \\ &= y_1 \left(-\frac{\mathrm{e}^{\frac{x^2}{2}}}{x} - \frac{i\sqrt{\pi}\,\sqrt{2}\,\mathrm{erf}\left(\frac{i\sqrt{2}\,x}{2}\right)}{2} \right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\mathrm{e}^{-\frac{x^2}{2}} x\right) + c_2 \left(\mathrm{e}^{-\frac{x^2}{2}} x \left(-\frac{\mathrm{e}^{\frac{x^2}{2}}}{x} - \frac{i\sqrt{\pi}\,\sqrt{2}\,\mathrm{erf}\left(\frac{i\sqrt{2}\,x}{2}\right)}{2} \right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$\frac{d^2}{dx^2}y(x) + x\left(\frac{d}{dx}y(x)\right) + 2y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite DE with series expansions

  ◦ Convert $x \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion

  $x \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k k\, x^k$

  ◦ Convert $\frac{d^2}{dx^2}y(x)$ to series expansion

  $\frac{d^2}{dx^2}y(x) = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$

  ◦ Shift index using $k- >k+2$

  $\frac{d^2}{dx^2}y(x) = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$

  Rewrite DE with series expansions

  $\sum_{k=0}^{\infty} \left(a_{k+2}(k+2)\,(k+1) + a_k(k+2)\right) x^k = 0$

- Each term in the series must be 0, giving the recursion relation

$$(k+2)(ka_{k+2} + a_k + a_{k+2}) = 0$$

- Recursion relation that defines the series solution to the ODE

$$\left[y(x) = \sum_{k=0}^{\infty} a_k x^k, a_{k+2} = -\frac{a_k}{k+1}\right]$$

2.1.20 Problem 20

Internal problem ID [9192]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 20
Date solved : `Monday, January 27, 2025 at 05:51:55 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$\left(x^2+1\right) y''-4xy'+6y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.249 (sec)

Writing the ode as

$$\left(x^2+1\right) y''-4xy'+6y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2+1 \\ B &= -4x \\ C &= 6 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r=\frac{-8}{\left(x^2+1\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -8 \\ t &= \left(x^2+1\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(-\frac{8}{\left(x^2+1\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.35: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 0 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (x^2+1)^2$. There is a pole at $x = i$ of order 2. There is a pole at $x = -i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{2}{(x-i)^2} + \frac{2}{(x+i)^2} + \frac{2i}{x-i} - \frac{2i}{x+i}$$

For the pole at $x = i$ let b be the coefficient of $\frac{1}{(x-i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1 \end{aligned}$$

For the pole at $x = -i$ let b be the coefficient of $\frac{1}{(x+i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1 \end{aligned}$$

Since the order of r at ∞ is $4 > 2$ then

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= 0 \\
\alpha_\infty^{-} &= 1
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = -\frac{8}{\left(x^2+1\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
i	2	0	2	-1
$-i$	2	0	2	-1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = 1$ then

$$
\begin{aligned}
d &= \alpha_\infty^{-} - \left(\alpha_{c_1}^{-} + \alpha_{c_2}^{+}\right) \\
&= 1 - (1) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x-c_1} \right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{+}}{x-c_2} \right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{1}{x-i} + \frac{2}{x+i} + (-)\,(0) \\
&= -\frac{1}{x-i} + \frac{2}{x+i} \\
&= \frac{x-3i}{x^2+1}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
\begin{aligned}
(0) + 2\left(-\frac{1}{x-i} + \frac{2}{x+i}\right)(0) + \left(\left(\frac{1}{(x-i)^2} - \frac{2}{(x+i)^2} \right) + \left(-\frac{1}{x-i} + \frac{2}{x+i} \right)^2 - \left(-\frac{8}{(x^2+1)^2} \right) \right) &= 0 \\
0 &= 0
\end{aligned}
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= pe^{\int \omega\,dx} \\
&= \mathrm{e}^{\int \left(-\frac{1}{x-i}+\frac{2}{x+i}\right)dx} \\
&= \frac{\left(x^2+1\right)^2}{\left(ix+1\right)^3}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-4x}{x^2+1}\,dx} \\
&= z_1 e^{\ln(x^2+1)} \\
&= z_1\left(x^2+1\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{\left(x^2+1\right)^3}{\left(ix+1\right)^3}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-4x}{x^2+1}\,dx}}{\left(y_1\right)^2}\,dx \\
&= y_1 \int \frac{e^{2\ln(x^2+1)}}{\left(y_1\right)^2}\,dx \\
&= y_1 \left(\frac{x^2-\frac{1}{3}}{\left(x+i\right)^3}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{\left(x^2+1\right)^3}{\left(ix+1\right)^3}\right) + c_2\left(\frac{\left(x^2+1\right)^3}{\left(ix+1\right)^3}\left(\frac{x^2-\frac{1}{3}}{\left(x+i\right)^3}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

2.1.21 Problem 21

Internal problem ID [9193]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 21
Date solved : `Monday, January 27, 2025 at 05:51:56 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$(1-x)\,y''+xy'-y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.231 (sec)

Writing the ode as

$$(1-x)\,y''+xy'-y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1-x \\ B &= x \\ C &= -1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{x^2-4x+6}{4\left(-1+x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2-4x+6 \\ t &= 4(-1+x)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{x^2-4x+6}{4\left(-1+x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.36: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(-1 + x)^2$. There is a pole at $x = 1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} - \frac{1}{2\,(-1 + x)} + \frac{3}{4\,(-1 + x)^2}$$

For the pole at $x = 1$ let b be the coefficient of $\frac{1}{(-1+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\
&= \sum_{i=0}^{0} a_i x^i
\end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} - \frac{1}{2x} + \frac{1}{x^3} + \frac{11}{4x^4} + \frac{21}{4x^5} + \frac{15}{2x^6} + \frac{6}{x^7} - \frac{117}{16x^8} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\
&= \frac{1}{2}
\end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{x^2 - 4x + 6}{4x^2 - 8x + 4} \\
&= Q + \frac{R}{4x^2 - 8x + 4} \\
&= \left(\frac{1}{4}\right) + \left(\frac{-2x + 5}{4x^2 - 8x + 4}\right) \\
&= \frac{1}{4} + \frac{-2x + 5}{4x^2 - 8x + 4}
\end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is -2. Dividing this by leading coefficient in t which is 4 gives $-\frac{1}{2}$. Now b can be found.

$$\begin{aligned}
b &= \left(-\frac{1}{2}\right) - (0) \\
&= -\frac{1}{2}
\end{aligned}$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \frac{1}{2} \\
\alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &&= -\frac{1}{2} \\
\alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &&= \frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{x^2 - 4x + 6}{4\left(-1 + x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
1	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	$-\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{+} = -\frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^{+} - \left(\alpha_{c_1}^{-}\right) \\
&= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

Substituting the above values in the above results in

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1} \right) + (+)[\sqrt{r}]_\infty \\
&= -\frac{1}{2\left(-1 + x\right)} + \left(\frac{1}{2}\right) \\
&= -\frac{1}{2\left(-1 + x\right)} + \frac{1}{2} \\
&= \frac{x - 2}{2x - 2}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{2(-1+x)} + \frac{1}{2}\right)(0) + \left(\left(\frac{1}{2(-1+x)^2}\right) + \left(-\frac{1}{2(-1+x)} + \frac{1}{2}\right)^2 - \left(\frac{x^2-4x+6}{4(-1+x)^2}\right)\right) = 0$$
$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega\, dx} \\ &= \mathrm{e}^{\int \left(-\frac{1}{2(-1+x)} + \frac{1}{2}\right) dx} \\ &= \frac{\mathrm{e}^{\frac{x}{2}}}{\sqrt{-1+x}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{x}{1-x}\, dx} \\ &= z_1 e^{\frac{x}{2} + \frac{\ln(-1+x)}{2}} \\ &= z_1\left(\sqrt{-1+x}\, \mathrm{e}^{\frac{x}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^x$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{x}{1-x}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{x+\ln(-1+x)}}{(y_1)^2}\, dx \\ &= y_1 \left(-\frac{x\, \mathrm{e}^{x+\ln(-1+x)} \mathrm{e}^{-2x}}{-1+x}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(\mathrm{e}^x) + c_2\left(\mathrm{e}^x\left(-\frac{x\, \mathrm{e}^{x+\ln(-1+x)} \mathrm{e}^{-2x}}{-1+x}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$(1-x)\left(\frac{d^2}{dx^2}y(x)\right)+x\left(\frac{d}{dx}y(x)\right)-y(x)=0$

- Highest derivative means the order of the ODE is 2

$\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

$\frac{d^2}{dx^2}y(x)=-\frac{y(x)}{x-1}+\frac{\left(\frac{d}{dx}y(x)\right)x}{x-1}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

$\frac{d^2}{dx^2}y(x)-\frac{\left(\frac{d}{dx}y(x)\right)x}{x-1}+\frac{y(x)}{x-1}=0$

☐ Check to see if $x_0=1$ is a regular singular point

- ◦ Define functions

  $\left[P_2(x)=-\frac{x}{x-1},P_3(x)=\frac{1}{x-1}\right]$

- ◦ $(x-1)\cdot P_2(x)$ is analytic at $x=1$

  $\left((x-1)\cdot P_2(x)\right)\bigg|_{x=1}=-1$

- ◦ $(x-1)^2\cdot P_3(x)$ is analytic at $x=1$

  $\left((x-1)^2\cdot P_3(x)\right)\bigg|_{x=1}=0$

- ◦ $x=1$is a regular singular point

  Check to see if $x_0=1$ is a regular singular point

  $x_0=1$

- Multiply by denominators

$(x-1)\left(\frac{d^2}{dx^2}y(x)\right)-x\left(\frac{d}{dx}y(x)\right)+y(x)=0$

- Change variables using $x=u+1$ so that the regular singular point is at $u=0$

$u\left(\frac{d^2}{du^2}y(u)\right)+(-u-1)\left(\frac{d}{du}y(u)\right)+y(u)=0$

- Assume series solution for $y(u)$

$y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

☐ Rewrite ODE with series expansions

- ◦ Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$

  $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,u^{k+r-1+m}$

- ◦ Shift index using $k->k+1-m$

  $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,u^{k+r}$

- ◦ Convert $u\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion

  $u\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,u^{k+r-1}$

- ◦ Shift index using $k->k+1$

  $u\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=-1}^{\infty}a_{k+1}(k+1+r)\,(k+r)\,u^{k+r}$

  Rewrite ODE with series expansions

  $a_0r(-2+r)\,u^{-1+r}+\left(\sum_{k=0}^{\infty}\left(a_{k+1}(k+1+r)\,(k+r-1)-a_k(k+r-1)\right)u^{k+r}\right)=0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$r(-2+r)=0$

- Values of r that satisfy the indicial equation
  $r \in \{0,2\}$
- Each term in the series must be 0, giving the recursion relation
  $(k+r-1)\left(a_{k+1}(k+1+r)-a_k\right)=0$
- Recursion relation that defines series solution to ODE
  $a_{k+1}=\frac{a_k}{k+1+r}$
- Recursion relation for $r=0$
  $a_{k+1}=\frac{a_k}{k+1}$
- Solution for $r=0$
  $\left[y(u)=\sum_{k=0}^{\infty} a_k u^k, a_{k+1}=\frac{a_k}{k+1}\right]$
- Revert the change of variables $u=x-1$
  $\left[y(x)=\sum_{k=0}^{\infty} a_k (x-1)^k, a_{k+1}=\frac{a_k}{k+1}\right]$
- Recursion relation for $r=2$
  $a_{k+1}=\frac{a_k}{k+3}$
- Solution for $r=2$
  $\left[y(u)=\sum_{k=0}^{\infty} a_k u^{k+2}, a_{k+1}=\frac{a_k}{k+3}\right]$
- Revert the change of variables $u=x-1$
  $\left[y(x)=\sum_{k=0}^{\infty} a_k (x-1)^{k+2}, a_{k+1}=\frac{a_k}{k+3}\right]$
- Combine solutions and rename parameters
  $\left[y(x)=\left(\sum_{k=0}^{\infty} a_k (x-1)^k\right)+\left(\sum_{k=0}^{\infty} b_k (x-1)^{k+2}\right), a_{k+1}=\frac{a_k}{k+1}, b_{k+1}=\frac{b_k}{k+3}\right]$

2.1.22 Problem 22

Internal problem ID [9194]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 22
Date solved : `Monday, January 27, 2025 at 05:51:56 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$2y'' + xy' + 3y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.244 (sec)

Writing the ode as

$$2y'' + xy' + 3y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2 \\ B &= x \\ C &= 3 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 - 20}{16} \tag{6}$$

Comparing the above to (5) shows that

$$s = x^2 - 20$$
$$t = 16$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2}{16} - \frac{5}{4}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.38: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 2 \\ &= -2 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \qquad (8) \end{aligned}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x}{4} - \frac{5}{2x} - \frac{25}{2x^3} - \frac{125}{x^5} - \frac{3125}{2x^7} - \frac{21875}{x^9} - \frac{328125}{x^{11}} - \frac{5156250}{x^{13}} + \dots \qquad (9)$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{4}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= \frac{x}{4} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{x^2}{16}$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 - 20}{16} \\ &= Q + \frac{R}{16} \\ &= \left(\frac{x^2}{16} - \frac{5}{4}\right) + (0) \\ &= \frac{x^2}{16} - \frac{5}{4} \end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is $-\frac{5}{4}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{5}{4}\right) - (0) \\ &= -\frac{5}{4} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{x}{4} \\ \alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-\frac{5}{4}}{\frac{1}{4}} - 1\right) &= -3 \\ \alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-\frac{5}{4}}{\frac{1}{4}} - 1\right) &= 2 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2}{16} - \frac{5}{4}$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
-2	$\frac{x}{4}$	-3	2

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 2$, and since there are no poles then

$$\begin{aligned} d &= \alpha_\infty^- \\ &= 2 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= (-)[\sqrt{r}]_\infty \\ &= 0 + (-)\left(\frac{x}{4}\right) \\ &= -\frac{x}{4} \\ &= -\frac{x}{4} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 2$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x^2 + a_1 x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{gathered} (2) + 2\left(-\frac{x}{4}\right)(2x + a_1) + \left(\left(-\frac{1}{4}\right) + \left(-\frac{x}{4}\right)^2 - \left(\frac{x^2}{16} - \frac{5}{4}\right)\right) = 0 \\ 2 + \frac{a_1 x}{2} + a_0 = 0 \end{gathered}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = -2, a_1 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^2 - 2$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= \left(x^2 - 2\right) e^{\int -\frac{x}{4} dx} \\ &= \left(x^2 - 2\right) e^{-\frac{x^2}{8}} \\ &= \left(x^2 - 2\right) e^{-\frac{x^2}{8}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2} \frac{x}{2} \, dx} \\ &= z_1 e^{-\frac{x^2}{8}} \\ &= z_1 \left(e^{-\frac{x^2}{8}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = e^{-\frac{x^2}{4}}\left(x^2-2\right)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x}{2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{x^2}{4}}}{(y_1)^2}\,dx \\
&= y_1 \left(\int \frac{e^{\frac{x^2}{4}}}{(x^2-2)^2}dx\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(e^{-\frac{x^2}{4}}\left(x^2-2\right)\right) + c_2\left(e^{-\frac{x^2}{4}}\left(x^2-2\right)\left(\int \frac{e^{\frac{x^2}{4}}}{(x^2-2)^2}dx\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve
$2\frac{d^2}{dx^2}y(x) + x\left(\frac{d}{dx}y(x)\right) + 3y(x) = 0$

- Highest derivative means the order of the ODE is 2
  $\frac{d^2}{dx^2}y(x)$
- Isolate 2nd derivative
  $\frac{d^2}{dx^2}y(x) = -\frac{x\left(\frac{d}{dx}y(x)\right)}{2} - \frac{3y(x)}{2}$
- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea
  $\frac{d^2}{dx^2}y(x) + \frac{x\left(\frac{d}{dx}y(x)\right)}{2} + \frac{3y(x)}{2} = 0$
- Multiply by denominators
  $2\frac{d^2}{dx^2}y(x) + x\left(\frac{d}{dx}y(x)\right) + 3y(x) = 0$
- Assume series solution for $y(x)$
  $y(x) = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite DE with series expansions

  - Convert $x\cdot\left(\frac{d}{dx}y(x)\right)$ to series expansion
    $x\cdot\left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k k\, x^k$
  - Convert $\frac{d^2}{dx^2}y(x)$ to series expansion
    $\frac{d^2}{dx^2}y(x) = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$
  - Shift index using $k- >k+2$

$\frac{d^2}{dx^2}y(x) = \sum_{k=0}^{\infty} a_{k+2}(k+2)(k+1)\, x^k$

Rewrite DE with series expansions

$\sum_{k=0}^{\infty} \left(2a_{k+2}(k+2)(k+1) + a_k(k+3)\right) x^k = 0$

- Each term in the series must be 0, giving the recursion relation

  $(2k^2 + 6k + 4)\, a_{k+2} + a_k(k+3) = 0$

- Recursion relation that defines the series solution to the ODE

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^k, a_{k+2} = -\frac{a_k(k+3)}{2(k^2+3k+2)}\right]$

Solve

$$y'' + xy' + 2y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.210 (sec)

Writing the ode as

$$y'' + xy' + 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= x \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A} dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 - 6}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2 - 6 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2}{4} - \frac{3}{2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.40: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 2 \\ &= -2 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x}{2} - \frac{3}{2x} - \frac{9}{4x^3} - \frac{27}{4x^5} - \frac{405}{16x^7} - \frac{1701}{16x^9} - \frac{15309}{32x^{11}} - \frac{72171}{32x^{13}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 1$ gives

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\
&= \frac{x}{2} \qquad (10)
\end{aligned}
$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$
\left([\sqrt{r}]_\infty\right)^2 = \frac{x^2}{4}
$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$
r = Q + \frac{R}{t}
$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{x^2 - 6}{4} \\
&= Q + \frac{R}{4} \\
&= \left(\frac{x^2}{4} - \frac{3}{2}\right) + (0) \\
&= \frac{x^2}{4} - \frac{3}{2}
\end{aligned}
$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is $-\frac{3}{2}$. Now b can be found.

$$
\begin{aligned}
b &= \left(-\frac{3}{2}\right) - (0) \\
&= -\frac{3}{2}
\end{aligned}
$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \frac{x}{2} \\
\alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-\frac{3}{2}}{\frac{1}{2}} - 1\right) &= -2 \\
\alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-\frac{3}{2}}{\frac{1}{2}} - 1\right) &= 1
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{x^2}{4} - \frac{3}{2}
$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
-2	$\frac{x}{2}$	-2	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$, and since there are no poles then

$$\begin{aligned} d &= \alpha_\infty^- \\ &= 1 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= (-)[\sqrt{r}]_\infty \\ &= 0 + (-)\left(\frac{x}{2}\right) \\ &= -\frac{x}{2} \\ &= -\frac{x}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(-\frac{x}{2}\right)(1) + \left(\left(-\frac{1}{2}\right) + \left(-\frac{x}{2}\right)^2 - \left(\frac{x^2}{4} - \frac{3}{2}\right)\right) &= 0 \\ a_0 &= 0 \end{aligned}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= pe^{\int \omega\, dx} \\ &= (x)\,e^{\int -\frac{x}{2}dx} \\ &= (x)\,e^{-\frac{x^2}{4}} \\ &= x\,e^{-\frac{x^2}{4}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{x}{1}\, dx} \\ &= z_1 e^{-\frac{x^2}{4}} \\ &= z_1\left(e^{-\frac{x^2}{4}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-\frac{x^2}{2}} x$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{x}{1}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-\frac{x^2}{2}}}{(y_1)^2}\, dx \\ &= y_1 \left(-\frac{\mathrm{e}^{\frac{x^2}{2}}}{x} - \frac{i\sqrt{\pi}\,\sqrt{2}\,\mathrm{erf}\left(\frac{i\sqrt{2}\,x}{2}\right)}{2} \right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\mathrm{e}^{-\frac{x^2}{2}} x\right) + c_2 \left(\mathrm{e}^{-\frac{x^2}{2}} x \left(-\frac{\mathrm{e}^{\frac{x^2}{2}}}{x} - \frac{i\sqrt{\pi}\,\sqrt{2}\,\mathrm{erf}\left(\frac{i\sqrt{2}\,x}{2}\right)}{2} \right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$\frac{d^2}{dx^2}y(x) + x\left(\frac{d}{dx}y(x)\right) + 2y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^k$

- ☐ Rewrite DE with series expansions

  - Convert $x \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion

    $x \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k k\, x^k$

  - Convert $\frac{d^2}{dx^2}y(x)$ to series expansion

    $\frac{d^2}{dx^2}y(x) = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$

  - Shift index using $k- >k+2$

    $\frac{d^2}{dx^2}y(x) = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$

  Rewrite DE with series expansions

  $\sum_{k=0}^{\infty} \left(a_{k+2}(k+2)\,(k+1) + a_k(k+2)\right) x^k = 0$

- Each term in the series must be 0, giving the recursion relation

$$(k+2)\left(k a_{k+2}+a_k+a_{k+2}\right)=0$$

- Recursion relation that defines the series solution to the ODE

$$\left[y(x)=\sum_{k=0}^{\infty} a_k x^k, a_{k+2}=-\frac{a_k}{k+1}\right]$$

2.1.24 Problem 24

Internal problem ID [9196]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 24
Date solved : `Monday, January 27, 2025 at 05:51:58 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$(1-x)\,y''+xy'-y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.242 (sec)

Writing the ode as

$$(1-x)\,y''+xy'-y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A&=1-x\\ B&=x\\ C&=-1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r&=\frac{s}{t} \\ &=\frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{x^2-4x+6}{4\left(-1+x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s&=x^2-4x+6\\ t&=4(-1+x)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{x^2-4x+6}{4\left(-1+x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.42: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(-1 + x)^2$. There is a pole at $x = 1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} + \frac{3}{4\,(-1+x)^2} - \frac{1}{2\,(-1+x)}$$

For the pole at $x = 1$ let b be the coefficient of $\frac{1}{(-1+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} - \frac{1}{2x} + \frac{1}{x^3} + \frac{11}{4x^4} + \frac{21}{4x^5} + \frac{15}{2x^6} + \frac{6}{x^7} - \frac{117}{16x^8} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 - 4x + 6}{4x^2 - 8x + 4} \\ &= Q + \frac{R}{4x^2 - 8x + 4} \\ &= \left(\frac{1}{4}\right) + \left(\frac{-2x + 5}{4x^2 - 8x + 4}\right) \\ &= \frac{1}{4} + \frac{-2x + 5}{4x^2 - 8x + 4} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is -2. Dividing this by leading coefficient in t which is 4 gives $-\frac{1}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{1}{2}\right) - (0) \\ &= -\frac{1}{2} \end{aligned}$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \frac{1}{2} \\
\alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &&= -\frac{1}{2} \\
\alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &&= \frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{x^2 - 4x + 6}{4(-1+x)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
1	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	$-\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = -\frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^-\right) \\
&= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty
$$

Substituting the above values in the above results in

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + (+)[\sqrt{r}]_\infty \\
&= -\frac{1}{2(-1+x)} + \left(\frac{1}{2}\right) \\
&= -\frac{1}{2(-1+x)} + \frac{1}{2} \\
&= \frac{x-2}{2x-2}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(-\frac{1}{2(-1+x)}+\frac{1}{2}\right)(0)+\left(\left(\frac{1}{2(-1+x)^2}\right)+\left(-\frac{1}{2(-1+x)}+\frac{1}{2}\right)^2-\left(\frac{x^2-4x+6}{4(-1+x)^2}\right)\right)=0$$
$$0=0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z''=rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx} \\
&= \mathrm{e}^{\int \left(-\frac{1}{2(-1+x)}+\frac{1}{2}\right)dx} \\
&= \frac{\mathrm{e}^{\frac{x}{2}}}{\sqrt{-1+x}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{x}{1-x}\, dx} \\
&= z_1 e^{\frac{x}{2}+\frac{\ln(-1+x)}{2}} \\
&= z_1\left(\sqrt{-1+x}\,\mathrm{e}^{\frac{x}{2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x}{1-x}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{x+\ln(-1+x)}}{(y_1)^2}\, dx \\
&= y_1\left(-\frac{x\,\mathrm{e}^{x+\ln(-1+x)}\mathrm{e}^{-2x}}{-1+x}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(\mathrm{e}^{x}) + c_2\left(\mathrm{e}^{x}\left(-\frac{x\,\mathrm{e}^{x+\ln(-1+x)}\mathrm{e}^{-2x}}{-1+x}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$(1-x)\left(\frac{d^2}{dx^2}y(x)\right)+x\left(\frac{d}{dx}y(x)\right)-y(x)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x)=-\frac{y(x)}{x-1}+\frac{\left(\frac{d}{dx}y(x)\right)x}{x-1}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x)-\frac{\left(\frac{d}{dx}y(x)\right)x}{x-1}+\frac{y(x)}{x-1}=0$

□ Check to see if $x_0=1$ is a regular singular point

  ◦ Define functions

    $\left[P_2(x)=-\frac{x}{x-1}, P_3(x)=\frac{1}{x-1}\right]$

  ◦ $(x-1)\cdot P_2(x)$ is analytic at $x=1$

    $\left.((x-1)\cdot P_2(x))\right|_{x=1}=-1$

  ◦ $(x-1)^2\cdot P_3(x)$ is analytic at $x=1$

    $\left.((x-1)^2\cdot P_3(x))\right|_{x=1}=0$

  ◦ $x=1$is a regular singular point

  Check to see if $x_0=1$ is a regular singular point

  $x_0=1$

- Multiply by denominators

  $(x-1)\left(\frac{d^2}{dx^2}y(x)\right)-x\left(\frac{d}{dx}y(x)\right)+y(x)=0$

- Change variables using $x=u+1$ so that the regular singular point is at $u=0$

  $u\left(\frac{d^2}{du^2}y(u)\right)+(-u-1)\left(\frac{d}{du}y(u)\right)+y(u)=0$

- Assume series solution for $y(u)$

  $y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$

    $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,u^{k+r-1+m}$

  ◦ Shift index using $k->k+1-m$

    $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,u^{k+r}$

  ◦ Convert $u\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion

    $u\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,u^{k+r-1}$

  ◦ Shift index using $k->k+1$

    $u\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=-1}^{\infty}a_{k+1}(k+1+r)\,(k+r)\,u^{k+r}$

  Rewrite ODE with series expansions

  $a_0r(-2+r)\,u^{-1+r}+\left(\sum_{k=0}^{\infty}\left(a_{k+1}(k+1+r)\,(k+r-1)-a_k(k+r-1)\right)u^{k+r}\right)=0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$r(-2+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{0, 2\}$

- Each term in the series must be 0, giving the recursion relation

  $(k+r-1)\left(a_{k+1}(k+1+r) - a_k\right) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+1} = \frac{a_k}{k+1+r}$

- Recursion relation for $r = 0$

  $a_{k+1} = \frac{a_k}{k+1}$

- Solution for $r = 0$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+1} = \frac{a_k}{k+1}\right]$

- Revert the change of variables $u = x - 1$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k (x-1)^k, a_{k+1} = \frac{a_k}{k+1}\right]$

- Recursion relation for $r = 2$

  $a_{k+1} = \frac{a_k}{k+3}$

- Solution for $r = 2$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+2}, a_{k+1} = \frac{a_k}{k+3}\right]$

- Revert the change of variables $u = x - 1$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k (x-1)^{k+2}, a_{k+1} = \frac{a_k}{k+3}\right]$

- Combine solutions and rename parameters

  $\left[y(x) = \left(\sum_{k=0}^{\infty} a_k (x-1)^k\right) + \left(\sum_{k=0}^{\infty} b_k (x-1)^{k+2}\right), a_{k+1} = \frac{a_k}{k+1}, b_{k+1} = \frac{b_k}{k+3}\right]$

Solve

$$y'' + xy' + 2y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.218 (sec)

Writing the ode as

$$y'' + xy' + 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= x \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 - 6}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2 - 6 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2}{4} - \frac{3}{2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.44: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 2 \\ &= -2 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x}{2} - \frac{3}{2x} - \frac{9}{4x^3} - \frac{27}{4x^5} - \frac{405}{16x^7} - \frac{1701}{16x^9} - \frac{15309}{32x^{11}} - \frac{72171}{32x^{13}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= \frac{x}{2}\end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{x^2}{4}$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned}r &= \frac{s}{t} \\ &= \frac{x^2 - 6}{4} \\ &= Q + \frac{R}{4} \\ &= \left(\frac{x^2}{4} - \frac{3}{2}\right) + (0) \\ &= \frac{x^2}{4} - \frac{3}{2}\end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is $-\frac{3}{2}$. Now b can be found.

$$\begin{aligned}b &= \left(-\frac{3}{2}\right) - (0) \\ &= -\frac{3}{2}\end{aligned}$$

Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= \frac{x}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{3}{2}}{\frac{1}{2}} - 1\right) &&= -2 \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{3}{2}}{\frac{1}{2}} - 1\right) &&= 1\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2}{4} - \frac{3}{2}$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-2	$\frac{x}{2}$	-2	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$, and since there are no poles then

$$\begin{aligned} d &= \alpha_\infty^- \\ &= 1 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= (-)[\sqrt{r}]_\infty \\ &= 0 + (-)\left(\frac{x}{2}\right) \\ &= -\frac{x}{2} \\ &= -\frac{x}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(-\frac{x}{2}\right)(1) + \left(\left(-\frac{1}{2}\right) + \left(-\frac{x}{2}\right)^2 - \left(\frac{x^2}{4} - \frac{3}{2}\right)\right) &= 0 \\ a_0 &= 0 \end{aligned}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= (x)\, \mathrm{e}^{\int -\frac{x}{2} dx} \\ &= (x)\, \mathrm{e}^{-\frac{x^2}{4}} \\ &= x\, \mathrm{e}^{-\frac{x^2}{4}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{x}{1} \, dx} \\ &= z_1 e^{-\frac{x^2}{4}} \\ &= z_1\left(\mathrm{e}^{-\frac{x^2}{4}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = e^{-\frac{x^2}{2}} x$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{x}{1}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-\frac{x^2}{2}}}{(y_1)^2}\, dx \\ &= y_1 \left(-\frac{e^{\frac{x^2}{2}}}{x} - \frac{i\sqrt{\pi}\,\sqrt{2}\,\mathrm{erf}\left(\frac{i\sqrt{2}\,x}{2}\right)}{2} \right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(e^{-\frac{x^2}{2}} x \right) + c_2 \left(e^{-\frac{x^2}{2}} x \left(-\frac{e^{\frac{x^2}{2}}}{x} - \frac{i\sqrt{\pi}\,\sqrt{2}\,\mathrm{erf}\left(\frac{i\sqrt{2}\,x}{2}\right)}{2} \right) \right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$\frac{d^2}{dx^2}y(x) + x\left(\frac{d}{dx}y(x)\right) + 2y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite DE with series expansions

  ◦ Convert $x \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion

  $x \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k k\, x^k$

  ◦ Convert $\frac{d^2}{dx^2}y(x)$ to series expansion

  $\frac{d^2}{dx^2}y(x) = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$

  ◦ Shift index using $k- >k+2$

  $\frac{d^2}{dx^2}y(x) = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$

  Rewrite DE with series expansions

  $\sum_{k=0}^{\infty} \left(a_{k+2}(k+2)\,(k+1) + a_k(k+2)\right) x^k = 0$

- Each term in the series must be 0, giving the recursion relation

$$(k+2)\left(k a_{k+2}+a_k+a_{k+2}\right)=0$$

- Recursion relation that defines the series solution to the ODE

$$\left[y(x)=\sum_{k=0}^{\infty} a_k x^k, a_{k+2}=-\frac{a_k}{k+1}\right]$$

Book : Collection of Kovacic problems
Section : section 1
Problem number : 26
Date solved : `Monday, January 27, 2025 at 05:51:59 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$\left(-x^2+4\right) y''+x y'+2 y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 1.058 (sec)

Writing the ode as

$$\left(-x^2+4\right) y''+x y'+2 y=0 \tag{1}$$

$$A y''+B y'+C y=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= -x^2+4 \\ B &= x \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=y e^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r=\frac{11x^2-24}{4\left(x^2-4\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 11x^2-24 \\ t &= 4\left(x^2-4\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{11x^2-24}{4\left(x^2-4\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.46: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^2-4)^2$. There is a pole at $x = 2$ of order 2. There is a pole at $x = -2$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Unable to find solution using case one

Attempting to find a solution using case $n = 2$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{17}{32\,(x-2)} - \frac{17}{32\,(x+2)} + \frac{5}{16\,(x+2)^2} + \frac{5}{16\,(x-2)^2}$$

For the pole at $x = 2$ let b be the coefficient of $\frac{1}{(x-2)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{5}{16}$. Hence

$$\begin{aligned} E_c &= \{2, 2+2\sqrt{1+4b}, 2-2\sqrt{1+4b}\} \\ &= \{-1, 2, 5\} \end{aligned}$$

For the pole at $x = -2$ let b be the coefficient of $\frac{1}{(x+2)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{5}{16}$. Hence

$$\begin{aligned} E_c &= \{2, 2+2\sqrt{1+4b}, 2-2\sqrt{1+4b}\} \\ &= \{-1, 2, 5\} \end{aligned}$$

Since the order of r at ∞ is 2 then let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{11x^2 - 24}{4\left(x^2-4\right)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{11}{4}$. Hence

$$\begin{aligned} E_\infty &= \{2, 2 + 2\sqrt{1+4b}, 2 - 2\sqrt{1+4b}\} \\ &= \{2\} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ for case 2 of Kovacic algorithm.

pole c location	pole order	E_c
2	2	$\{-1, 2, 5\}$
-2	2	$\{-1, 2, 5\}$

Order of r at ∞	E_∞
2	$\{2\}$

Using the family $\{e_1, e_2, \ldots, e_\infty\}$ given by

$$e_1 = -1,\ e_2 = -1,\ e_\infty = 2$$

Gives a non negative integer d (the degree of the polynomial $p(x)$), which is generated using

$$\begin{aligned} d &= \frac{1}{2}\left(e_\infty - \sum_{c\in\Gamma} e_c\right) \\ &= \frac{1}{2}(2 - (-1 + (-1))) \\ &= 2 \end{aligned}$$

We now form the following rational function

$$\begin{aligned} \theta &= \frac{1}{2}\sum_{c\in\Gamma} \frac{e_c}{x-c} \\ &= \frac{1}{2}\left(\frac{-1}{(x-(2))} + \frac{-1}{(x-(-2))}\right) \\ &= -\frac{1}{2(x-2)} - \frac{1}{2(x+2)} \end{aligned}$$

Now we search for a monic polynomial $p(x)$ of degree $d = 2$ such that

$$p''' + 3\theta p'' + \left(3\theta^2 + 3\theta' - 4r\right)p' + \left(\theta'' + 3\theta\theta' + \theta^3 - 4r\theta - 2r'\right)p = 0 \tag{1A}$$

Since $d = 2$, then letting

$$p = x^2 + a_1 x + a_0 \tag{2A}$$

Substituting p and θ into Eq. (1A) gives

$$\frac{11x^2 a_1 + 16(6 + a_0)\,x + 36a_1}{\left(x^2-4\right)^2} = 0$$

And solving for p gives

$$p = x^2 - 6$$

Now that $p(x)$ is found let

$$\begin{aligned}\phi &= \theta + \frac{p'}{p}\\ &= \frac{2x}{x^2-6} - \frac{1}{2(x-2)} - \frac{1}{2(x+2)}\end{aligned}$$

Let ω be the solution of

$$\omega^2 - \phi\omega + \left(\frac{1}{2}\phi' + \frac{1}{2}\phi^2 - r\right) = 0$$

Substituting the values for ϕ and r into the above equation gives

$$w^2 - \left(\frac{2x}{x^2-6} - \frac{1}{2(x-2)} - \frac{1}{2(x+2)}\right)w + \frac{-11x^4+74x^2-128}{4x^6-56x^4+256x^2-384} = 0$$

Solving for ω gives

$$\omega = \frac{2\sqrt{3}\,x^2\sqrt{x^2-4} + x^3 - 8\sqrt{3}\,\sqrt{x^2-4} - 2x}{2(x^2-6)(x-2)(x+2)}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}z_1(x) &= e^{\int \omega\,dx}\\ &= e^{\int \frac{2\sqrt{3}\,x^2\sqrt{x^2-4}+x^3-8\sqrt{3}\,\sqrt{x^2-4}-2x}{2\left(x^2-6\right)(x-2)(x+2)}dx}\\ &= \frac{\sqrt{x^2-6}\left(x+\sqrt{x^2-4}\right)^{\sqrt{3}} \mathrm{e}^{-\frac{\operatorname{arctanh}\left(\frac{\left(\sqrt{2}\,\sqrt{3}\,x-4\right)\sqrt{2}}{2\sqrt{x^2-4}}\right)}{2} - \frac{\operatorname{arctanh}\left(\frac{\left(4+\sqrt{2}\,\sqrt{3}\,x\right)\sqrt{2}}{2\sqrt{x^2-4}}\right)}{2}}}{(x-2)^{1/4}(x+2)^{1/4}}\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}\\ &= z_1 e^{-\int \frac{1}{2}\frac{x}{-x^2+4}\,dx}\\ &= z_1 e^{\frac{\ln\left(x^2-4\right)}{4}}\\ &= z_1\left(\left(x^2-4\right)^{1/4}\right)\end{aligned}$$

Which simplifies to

$$y_1 = \sqrt{x^2-6}\left(x+\sqrt{x^2-4}\right)^{\sqrt{3}} \mathrm{e}^{-\frac{\operatorname{arctanh}\left(\frac{x\sqrt{6}-4}{\sqrt{2x^2-8}}\right)}{2} - \frac{\operatorname{arctanh}\left(\frac{4+x\sqrt{6}}{\sqrt{2x^2-8}}\right)}{2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1\int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}y_2 &= y_1\int \frac{e^{\int -\frac{x}{-x^2+4}\,dx}}{(y_1)^2}\,dx\\ &= y_1\int \frac{e^{\frac{\ln\left(x^2-4\right)}{2}}}{(y_1)^2}\,dx\\ &= y_1\left(\int \frac{\sqrt{x^2-4}\left(x+\sqrt{x^2-4}\right)^{-2\sqrt{3}} \mathrm{e}^{\operatorname{arctanh}\left(\frac{x\sqrt{6}-4}{\sqrt{2x^2-8}}\right)+\operatorname{arctanh}\left(\frac{4+x\sqrt{6}}{\sqrt{2x^2-8}}\right)}}{x^2-6}dx\right)\end{aligned}$$

Therefore the solution is

$$y = c_1y_1 + c_2y_2$$

$$= c_1\left(\sqrt{x^2-6}\left(x+\sqrt{x^2-4}\right)^{\sqrt{3}} e^{-\frac{\operatorname{arctanh}\left(\frac{x\sqrt{6}-4}{\sqrt{2x^2-8}}\right)}{2}-\frac{\operatorname{arctanh}\left(\frac{4+x\sqrt{6}}{\sqrt{2x^2-8}}\right)}{2}}\right) + c_2\left(\sqrt{x^2-6}\left(x\right.\right.$$

$$\left.+\sqrt{x^2-4}\right)^{\sqrt{3}} e^{-\frac{\operatorname{arctanh}\left(\frac{x\sqrt{6}-4}{\sqrt{2x^2-8}}\right)}{2}-\frac{\operatorname{arctanh}\left(\frac{4+x\sqrt{6}}{\sqrt{2x^2-8}}\right)}{2}}\left(\int \frac{\sqrt{x^2-4}\left(x+\sqrt{x^2-4}\right)^{-2\sqrt{3}} e^{\operatorname{arctanh}\left(\frac{x\sqrt{6}-4}{\sqrt{2x^2-8}}\right)+\operatorname{arctanh}\left(\frac{4}{\sqrt{}}\right.}}{x^2-6}\right.$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$(-x^2+4)\left(\frac{d^2}{dx^2}y(x)\right)+x\left(\frac{d}{dx}y(x)\right)+2y(x)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$
- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x)=\frac{2y(x)}{x^2-4}+\frac{\left(\frac{d}{dx}y(x)\right)x}{x^2-4}$
- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x)-\frac{\left(\frac{d}{dx}y(x)\right)x}{x^2-4}-\frac{2y(x)}{x^2-4}=0$
- □ Check to see if x_0 is a regular singular point
  - Define functions

    $\left[P_2(x)=-\frac{x}{x^2-4}, P_3(x)=-\frac{2}{x^2-4}\right]$
  - $(x+2)\cdot P_2(x)$ is analytic at $x=-2$

    $\left((x+2)\cdot P_2(x)\right)\Big|_{x=-2}=-\frac{1}{2}$
  - $(x+2)^2\cdot P_3(x)$ is analytic at $x=-2$

    $\left((x+2)^2\cdot P_3(x)\right)\Big|_{x=-2}=0$
  - $x=-2$is a regular singular point

    Check to see if x_0 is a regular singular point

    $x_0=-2$
- Multiply by denominators

  $(x^2-4)\left(\frac{d^2}{dx^2}y(x)\right)-x\left(\frac{d}{dx}y(x)\right)-2y(x)=0$
- Change variables using $x=u-2$ so that the regular singular point is at $u=0$

  $(u^2-4u)\left(\frac{d^2}{du^2}y(u)\right)+(-u+2)\left(\frac{d}{du}y(u)\right)-2y(u)=0$
- Assume series solution for $y(u)$

  $y(u)=\sum_{k=0}^{\infty} a_k u^{k+r}$
- □ Rewrite ODE with series expansions
  - Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$

    $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty} a_k(k+r)\,u^{k+r-1+m}$
  - Shift index using $k->k+1-m$

$$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$$

- ◦ Convert $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m = 1..2$

$$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, u^{k+r-2+m}$$

- ◦ Shift index using $k- >k+2-m$

$$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, u^{k+r}$$

Rewrite ODE with series expansions

$$-2a_0r(-3+2r)\, u^{-1+r} + \left(\sum_{k=0}^{\infty} \left(-2a_{k+1}(k+1+r)\,(2k-1+2r) + a_k(k^2+2kr+r^2-2k-2r-\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
$-2r(-3+2r) = 0$
- Values of r that satisfy the indicial equation
$r \in \left\{0, \frac{3}{2}\right\}$
- Each term in the series must be 0, giving the recursion relation
$-4\left(k+r-\frac{1}{2}\right)(k+1+r)\, a_{k+1} + \left(k^2+(2r-2)\, k+r^2-2r-2\right) a_k = 0$
- Recursion relation that defines series solution to ODE
$a_{k+1} = \frac{(k^2+2kr+r^2-2k-2r-2)a_k}{2(2k-1+2r)(k+1+r)}$
- Recursion relation for $r = 0$
$a_{k+1} = \frac{(k^2-2k-2)a_k}{2(2k-1)(k+1)}$
- Solution for $r = 0$
$\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+1} = \frac{(k^2-2k-2)a_k}{2(2k-1)(k+1)}\right]$
- Revert the change of variables $u = x+2$
$\left[y(x) = \sum_{k=0}^{\infty} a_k(x+2)^k, a_{k+1} = \frac{(k^2-2k-2)a_k}{2(2k-1)(k+1)}\right]$
- Recursion relation for $r = \frac{3}{2}$
$a_{k+1} = \frac{(k^2+k-\frac{11}{4})a_k}{2(2k+2)(k+\frac{5}{2})}$
- Solution for $r = \frac{3}{2}$
$\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+\frac{3}{2}}, a_{k+1} = \frac{(k^2+k-\frac{11}{4})a_k}{2(2k+2)(k+\frac{5}{2})}\right]$
- Revert the change of variables $u = x+2$
$\left[y(x) = \sum_{k=0}^{\infty} a_k(x+2)^{k+\frac{3}{2}}, a_{k+1} = \frac{(k^2+k-\frac{11}{4})a_k}{2(2k+2)(k+\frac{5}{2})}\right]$
- Combine solutions and rename parameters
$\left[y(x) = \left(\sum_{k=0}^{\infty} a_k(x+2)^k\right) + \left(\sum_{k=0}^{\infty} b_k(x+2)^{k+\frac{3}{2}}\right), a_{k+1} = \frac{(k^2-2k-2)a_k}{2(2k-1)(k+1)}, b_{k+1} = \frac{(k^2+k-\frac{11}{4})b_k}{2(2k+2)(k+\frac{5}{2})}\right]$

2.1.27 Problem 27

Internal problem ID [9199]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 27
Date solved : `Monday, January 27, 2025 at 05:52:00 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$4x^2y'' - 4xy' + \left(-16x^2+3\right)y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.087 (sec)

Writing the ode as

$$4x^2y'' - 4xy' + \left(-16x^2+3\right)y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4x^2 \\ B &= -4x \\ C &= -16x^2+3 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{4}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 4 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 4z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.48: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 4$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-2x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-4x}{4x^2}\, dx} \\ &= z_1 e^{\frac{\ln(x)}{2}} \\ &= z_1\left(\sqrt{x}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \sqrt{x}\, \mathrm{e}^{-2x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-4x}{4x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{\ln(x)}}{(y_1)^2}\,dx \\
&= y_1 \left(\frac{e^{4x}}{4}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\sqrt{x}\,e^{-2x}\right) + c_2 \left(\sqrt{x}\,e^{-2x}\left(\frac{e^{4x}}{4}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$4x^2\left(\frac{d^2}{dx^2}y(x)\right) - 4x\left(\frac{d}{dx}y(x)\right) + (-16x^2+3)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = \frac{(16x^2-3)y(x)}{4x^2} + \frac{\frac{d}{dx}y(x)}{x}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x) - \frac{\frac{d}{dx}y(x)}{x} - \frac{(16x^2-3)y(x)}{4x^2} = 0$

- □ Check to see if $x_0 = 0$ is a regular singular point
  - Define functions

    $\left[P_2(x) = -\frac{1}{x}, P_3(x) = -\frac{16x^2-3}{4x^2}\right]$

  - $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left.(x \cdot P_2(x))\right|_{x=0} = -1$

  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $\left.(x^2 \cdot P_3(x))\right|_{x=0} = \frac{3}{4}$

  - $x = 0$is a regular singular point

    Check to see if $x_0 = 0$ is a regular singular point

    $x_0 = 0$

- Multiply by denominators

  $4x^2\left(\frac{d^2}{dx^2}y(x)\right) - 4x\left(\frac{d}{dx}y(x)\right) + (-16x^2+3)\,y(x) = 0$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

- □ Rewrite ODE with series expansions
  - Convert $x^m \cdot y(x)$ to series expansion for $m = 0..2$

    $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- ∘ Shift index using $k- >k-m$

  $x^{m}\cdot y(x)=\sum_{k=m}^{\infty}a_{k-m}x^{k+r}$

- ∘ Convert $x\cdot\left(\frac{d}{dx}y(x)\right)$ to series expansion

  $x\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=0}^{\infty}a_{k}(k+r)\,x^{k+r}$

- ∘ Convert $x^{2}\cdot\left(\frac{d^{2}}{dx^{2}}y(x)\right)$ to series expansion

  $x^{2}\cdot\left(\frac{d^{2}}{dx^{2}}y(x)\right)=\sum_{k=0}^{\infty}a_{k}(k+r)\,(k+r-1)\,x^{k+r}$

  Rewrite ODE with series expansions

  $a_{0}(-1+2r)\,(-3+2r)\,x^{r}+a_{1}(1+2r)\,(-1+2r)\,x^{1+r}+\left(\sum_{k=2}^{\infty}(a_{k}(2k+2r-1)\,(2k+2r-3)-16a$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-1+2r)\,(-3+2r)=0$

- Values of r that satisfy the indicial equation

  $r\in\left\{\frac{1}{2},\frac{3}{2}\right\}$

- Each term must be 0

  $a_{1}(1+2r)\,(-1+2r)=0$

- Solve for the dependent coefficient(s)

  $a_{1}=0$

- Each term in the series must be 0, giving the recursion relation

  $4\left(k+r-\frac{1}{2}\right)\left(k+r-\frac{3}{2}\right)a_{k}-16a_{k-2}=0$

- Shift index using $k- >k+2$

  $4\left(k+\frac{3}{2}+r\right)\left(k+\frac{1}{2}+r\right)a_{k+2}-16a_{k}=0$

- Recursion relation that defines series solution to ODE

  $a_{k+2}=\frac{16a_{k}}{(2k+3+2r)(2k+1+2r)}$

- Recursion relation for $r=\frac{1}{2}$

  $a_{k+2}=\frac{16a_{k}}{(2k+4)(2k+2)}$

- Solution for $r=\frac{1}{2}$

  $\left[y(x)=\sum_{k=0}^{\infty}a_{k}x^{k+\frac{1}{2}},a_{k+2}=\frac{16a_{k}}{(2k+4)(2k+2)},a_{1}=0\right]$

- Recursion relation for $r=\frac{3}{2}$

  $a_{k+2}=\frac{16a_{k}}{(2k+6)(2k+4)}$

- Solution for $r=\frac{3}{2}$

  $\left[y(x)=\sum_{k=0}^{\infty}a_{k}x^{k+\frac{3}{2}},a_{k+2}=\frac{16a_{k}}{(2k+6)(2k+4)},a_{1}=0\right]$

- Combine solutions and rename parameters

  $\left[y(x)=\left(\sum_{k=0}^{\infty}a_{k}x^{k+\frac{1}{2}}\right)+\left(\sum_{k=0}^{\infty}b_{k}x^{k+\frac{3}{2}}\right),a_{k+2}=\frac{16a_{k}}{(2k+4)(2k+2)},a_{1}=0,b_{k+2}=\frac{16b_{k}}{(2k+6)(2k+4)},b_{1}=0\right]$

2.1.28 Problem 28

Internal problem ID [9200]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 28
Date solved : `Monday, January 27, 2025 at 05:52:01 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$(x-1)\, y'' - x y' + y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.228 (sec)

Writing the ode as

$$(x-1)\, y'' - x y' + y = 0 \tag{1}$$
$$A y'' + B y' + C y = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x-1 \\ B &= -x \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 - 4x + 6}{4\,(x-1)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2 - 4x + 6 \\ t &= 4(x-1)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2 - 4x + 6}{4\,(x-1)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.50: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x-1)^2$. There is a pole at $x = 1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} + \frac{3}{4(x-1)^2} - \frac{1}{2(x-1)}$$

For the pole at $x = 1$ let b be the coefficient of $\frac{1}{(x-1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} - \frac{1}{2x} + \frac{1}{x^3} + \frac{11}{4x^4} + \frac{21}{4x^5} + \frac{15}{2x^6} + \frac{6}{x^7} - \frac{117}{16x^8} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 - 4x + 6}{4x^2 - 8x + 4} \\ &= Q + \frac{R}{4x^2 - 8x + 4} \\ &= \left(\frac{1}{4}\right) + \left(\frac{-2x + 5}{4x^2 - 8x + 4}\right) \\ &= \frac{1}{4} + \frac{-2x + 5}{4x^2 - 8x + 4} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is -2. Dividing this by leading coefficient in t which is 4 gives $-\frac{1}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{1}{2}\right) - (0) \\ &= -\frac{1}{2} \end{aligned}$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \frac{1}{2} \\
\alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &= -\frac{1}{2} \\
\alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &= \frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{x^2 - 4x + 6}{4(x-1)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
1	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	$-\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = -\frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^-\right) \\
&= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty
$$

Substituting the above values in the above results in

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + (+)[\sqrt{r}]_\infty \\
&= -\frac{1}{2(x-1)} + \left(\frac{1}{2}\right) \\
&= -\frac{1}{2(x-1)} + \frac{1}{2} \\
&= \frac{x-2}{2x-2}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{2(x-1)} + \frac{1}{2}\right)(0) + \left(\left(\frac{1}{2(x-1)^2}\right) + \left(-\frac{1}{2(x-1)} + \frac{1}{2}\right)^2 - \left(\frac{x^2-4x+6}{4(x-1)^2}\right)\right) = 0$$

$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= e^{\int \left(-\frac{1}{2(x-1)} + \frac{1}{2}\right) dx} \\
&= \frac{e^{\frac{x}{2}}}{\sqrt{x-1}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-x}{x-1} \, dx} \\
&= z_1 e^{\frac{x}{2} + \frac{\ln(x-1)}{2}} \\
&= z_1 \left(\sqrt{x-1}\, e^{\frac{x}{2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = e^x$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-x}{x-1} \, dx}}{(y_1)^2} \, dx \\
&= y_1 \int \frac{e^{x+\ln(x-1)}}{(y_1)^2} \, dx \\
&= y_1 \left(-\frac{x\, e^{x+\ln(x-1)} e^{-2x}}{x-1}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 (e^x) + c_2 \left(e^x \left(-\frac{x\, e^{x+\ln(x-1)} e^{-2x}}{x-1}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$(x-1)\left(\frac{d^2}{dx^2}y(x)\right)-x\left(\frac{d}{dx}y(x)\right)+y(x)=0$

- Highest derivative means the order of the ODE is 2

$\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

$\frac{d^2}{dx^2}y(x)=-\frac{y(x)}{x-1}+\frac{\left(\frac{d}{dx}y(x)\right)x}{x-1}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

$\frac{d^2}{dx^2}y(x)-\frac{\left(\frac{d}{dx}y(x)\right)x}{x-1}+\frac{y(x)}{x-1}=0$

□ Check to see if $x_0=1$ is a regular singular point

- Define functions

$\left[P_2(x)=-\frac{x}{x-1},P_3(x)=\frac{1}{x-1}\right]$

- $(x-1)\cdot P_2(x)$ is analytic at $x=1$

$\left((x-1)\cdot P_2(x)\right)\Big|_{x=1}=-1$

- $(x-1)^2\cdot P_3(x)$ is analytic at $x=1$

$\left((x-1)^2\cdot P_3(x)\right)\Big|_{x=1}=0$

- $x=1$is a regular singular point

Check to see if $x_0=1$ is a regular singular point

$x_0=1$

- Multiply by denominators

$(x-1)\left(\frac{d^2}{dx^2}y(x)\right)-x\left(\frac{d}{dx}y(x)\right)+y(x)=0$

- Change variables using $x=u+1$ so that the regular singular point is at $u=0$

$u\left(\frac{d^2}{du^2}y(u)\right)+(-u-1)\left(\frac{d}{du}y(u)\right)+y(u)=0$

- Assume series solution for $y(u)$

$y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

□ Rewrite ODE with series expansions

- Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$

$u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,u^{k+r-1+m}$

- Shift index using $k->k+1-m$

$u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,u^{k+r}$

- Convert $u\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion

$u\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,u^{k+r-1}$

- Shift index using $k->k+1$

$u\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=-1}^{\infty}a_{k+1}(k+1+r)\,(k+r)\,u^{k+r}$

Rewrite ODE with series expansions

$a_0r(-2+r)\,u^{-1+r}+\left(\sum_{k=0}^{\infty}\left(a_{k+1}(k+1+r)\,(k+r-1)-a_k(k+r-1)\right)u^{k+r}\right)=0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$r(-2+r) = 0$

- Values of r that satisfy the indicial equation
  $r \in \{0, 2\}$
- Each term in the series must be 0, giving the recursion relation
  $(k+r-1)\left(a_{k+1}(k+1+r) - a_k\right) = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+1} = \frac{a_k}{k+1+r}$
- Recursion relation for $r = 0$
  $a_{k+1} = \frac{a_k}{k+1}$
- Solution for $r = 0$
  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+1} = \frac{a_k}{k+1}\right]$
- Revert the change of variables $u = x - 1$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k (x-1)^k, a_{k+1} = \frac{a_k}{k+1}\right]$
- Recursion relation for $r = 2$
  $a_{k+1} = \frac{a_k}{k+3}$
- Solution for $r = 2$
  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+2}, a_{k+1} = \frac{a_k}{k+3}\right]$
- Revert the change of variables $u = x - 1$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k (x-1)^{k+2}, a_{k+1} = \frac{a_k}{k+3}\right]$
- Combine solutions and rename parameters
  $\left[y(x) = \left(\sum_{k=0}^{\infty} a_k (x-1)^k\right) + \left(\sum_{k=0}^{\infty} b_k (x-1)^{k+2}\right), a_{k+1} = \frac{a_k}{k+1}, b_{k+1} = \frac{b_k}{k+3}\right]$

2.1.29 Problem 29

Internal problem ID [9201]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 29
Date solved : `Monday, January 27, 2025 at 05:52:02 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' - 2xy' + \left(x^2+2\right) y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.125 (sec)

Writing the ode as

$$x^2y'' - 2xy' + \left(x^2+2\right) y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -2x \\ C &= x^2+2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.52: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-2x}{x^2}\, dx} \\ &= z_1 e^{\ln(x)} \\ &= z_1(x) \end{aligned}$$

Which simplifies to

$$y_1 = x\cos(x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-2x}{x^2} dx}}{(y_1)^2} dx \\
&= y_1 \int \frac{e^{2\ln(x)}}{(y_1)^2} dx \\
&= y_1(\tan(x))
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(x\cos(x)) + c_2(x\cos(x)(\tan(x)))
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve
$x^2\left(\frac{d^2}{dx^2}y(x)\right) - 2x\left(\frac{d}{dx}y(x)\right) + (x^2+2)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2
  $\frac{d^2}{dx^2}y(x)$
- Isolate 2nd derivative
  $\frac{d^2}{dx^2}y(x) = -\frac{(x^2+2)y(x)}{x^2} + \frac{2\left(\frac{d}{dx}y(x)\right)}{x}$
- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear
  $\frac{d^2}{dx^2}y(x) - \frac{2\left(\frac{d}{dx}y(x)\right)}{x} + \frac{(x^2+2)y(x)}{x^2} = 0$
- □ Check to see if $x_0 = 0$ is a regular singular point
  - Define functions
    $\left[P_2(x) = -\frac{2}{x}, P_3(x) = \frac{x^2+2}{x^2}\right]$
  - $x \cdot P_2(x)$ is analytic at $x = 0$
    $\left.(x \cdot P_2(x))\right|_{x=0} = -2$
  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$
    $\left.(x^2 \cdot P_3(x))\right|_{x=0} = 2$
  - $x = 0$is a regular singular point
    Check to see if $x_0 = 0$ is a regular singular point
    $x_0 = 0$
- Multiply by denominators
  $x^2\left(\frac{d^2}{dx^2}y(x)\right) - 2x\left(\frac{d}{dx}y(x)\right) + (x^2+2)\,y(x) = 0$
- Assume series solution for $y(x)$
  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$
- □ Rewrite ODE with series expansions
  - Convert $x^m \cdot y(x)$ to series expansion for $m = 0..2$
    $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$
  - Shift index using $k- > k - m$

$$x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$$

- Convert $x \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion

$$x \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r}$$

- Convert $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

$$x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0(-1+r)\,(-2+r)\, x^r + a_1 r(-1+r)\, x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(k+r-1)\,(k+r-2) + a_{k-2}\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$(-1+r)\,(-2+r) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \{1, 2\}$$

- Each term must be 0

$$a_1 r(-1+r) = 0$$

- Solve for the dependent coefficient(s)

$$a_1 = 0$$

- Each term in the series must be 0, giving the recursion relation

$$a_k(k+r-1)\,(k+r-2) + a_{k-2} = 0$$

- Shift index using $k- >k+2$

$$a_{k+2}(k+1+r)\,(k+r) + a_k = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+2} = -\frac{a_k}{(k+1+r)(k+r)}$$

- Recursion relation for $r = 1$

$$a_{k+2} = -\frac{a_k}{(k+2)(k+1)}$$

- Solution for $r = 1$

$$\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+1}, a_{k+2} = -\frac{a_k}{(k+2)(k+1)}, a_1 = 0\right]$$

- Recursion relation for $r = 2$

$$a_{k+2} = -\frac{a_k}{(k+3)(k+2)}$$

- Solution for $r = 2$

$$\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+2}, a_{k+2} = -\frac{a_k}{(k+3)(k+2)}, a_1 = 0\right]$$

- Combine solutions and rename parameters

$$\left[y(x) = \left(\sum_{k=0}^{\infty} a_k x^{k+1}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+2}\right), a_{k+2} = -\frac{a_k}{(k+2)(k+1)}, a_1 = 0, b_{k+2} = -\frac{b_k}{(k+3)(k+2)}, b_1 = 0\right]$$

2.1.30 Problem 31

Internal problem ID [9202]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 31
Date solved : `Monday, January 27, 2025 at 05:52:02 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$\left(x^2-2x\right)y''+\left(-x^2+2\right)y'+(2x-2)\,y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.314 (sec)

Writing the ode as

$$\left(x^2-2x\right)y''+\left(-x^2+2\right)y'+(2x-2)\,y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=x^2-2x\\B&=-x^2+2\\C&=2x-2\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned}r&=\frac{s}{t}\\&=\frac{2AB'-2BA'+B^2-4AC}{4A^2}\end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{x^4-8x^3+24x^2-24x+12}{4\left(x^2-2x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned}s&=x^4-8x^3+24x^2-24x+12\\t&=4\left(x^2-2x\right)^2\end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{x^4-8x^3+24x^2-24x+12}{4\left(x^2-2x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.54: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 4 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^2 - 2x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = 2$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} - \frac{3}{4x} - \frac{1}{4(x-2)} + \frac{3}{4x^2} + \frac{3}{4(x-2)^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

For the pole at $x = 2$ let b be the coefficient of $\frac{1}{(x-2)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\
&= \sum_{i=0}^{0} a_i x^i
\end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} - \frac{1}{x} + \frac{2}{x^3} + \frac{11}{x^4} + \frac{42}{x^5} + \frac{132}{x^6} + \frac{348}{x^7} + \frac{711}{x^8} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\
&= \frac{1}{2}
\end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{x^4 - 8x^3 + 24x^2 - 24x + 12}{4x^4 - 16x^3 + 16x^2} \\
&= Q + \frac{R}{4x^4 - 16x^3 + 16x^2} \\
&= \left(\frac{1}{4}\right) + \left(\frac{-4x^3 + 20x^2 - 24x + 12}{4x^4 - 16x^3 + 16x^2}\right) \\
&= \frac{1}{4} + \frac{-4x^3 + 20x^2 - 24x + 12}{4x^4 - 16x^3 + 16x^2}
\end{aligned}$$

Since the degree of t is 4, then we see that the coefficient of the term x^3 in the remainder R is -4. Dividing this by leading coefficient in t which is 4 gives -1. Now b can be found.

$$\begin{aligned}
b &= (-1) - (0) \\
&= -1
\end{aligned}$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \frac{1}{2} \\
\alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-1}{\frac{1}{2}} - 0\right) &&= -1 \\
\alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-1}{\frac{1}{2}} - 0\right) &&= 1
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{x^4 - 8x^3 + 24x^2 - 24x + 12}{4\left(x^2 - 2x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{3}{2}$	$-\frac{1}{2}$
2	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
0	$\frac{1}{2}$	-1	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{+} = -1$ then

$$
\begin{aligned}
d &= \alpha_\infty^{+} - \left(\alpha_{c_1}^{-} + \alpha_{c_2}^{-}\right) \\
&= -1 - (-1) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

Substituting the above values in the above results in

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{-}}{x - c_2} \right) + (+)[\sqrt{r}]_\infty \\
&= -\frac{1}{2x} - \frac{1}{2\left(x - 2\right)} + \left(\frac{1}{2}\right) \\
&= -\frac{1}{2x} - \frac{1}{2\left(x - 2\right)} + \frac{1}{2} \\
&= -\frac{1}{2x} - \frac{1}{2x - 4} + \frac{1}{2}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{2x} - \frac{1}{2(x-2)} + \frac{1}{2}\right)(0) + \left(\left(\frac{1}{2x^2} + \frac{1}{2(x-2)^2}\right) + \left(-\frac{1}{2x} - \frac{1}{2(x-2)} + \frac{1}{2}\right)^2 - \left(\frac{x^4 - 8x^3 +}{4(}\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= \mathrm{e}^{\int \left(-\frac{1}{2x} - \frac{1}{2(x-2)} + \frac{1}{2}\right) dx} \\ &= \frac{\mathrm{e}^{\frac{x}{2}}}{\sqrt{x-2}\,\sqrt{x}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-x^2+2}{x^2-2x} \, dx} \\ &= z_1 e^{\frac{x}{2} + \frac{\ln(x-2)}{2} + \frac{\ln(x)}{2}} \\ &= z_1 \left(\sqrt{x-2}\,\sqrt{x}\,\mathrm{e}^{\frac{x}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{\sqrt{x-2}\,\sqrt{x}\,\mathrm{e}^{x}}{\sqrt{x(x-2)}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-x^2+2}{x^2-2x} \, dx}}{(y_1)^2} \, dx \\ &= y_1 \int \frac{e^{x+\ln(x-2)+\ln(x)}}{(y_1)^2} \, dx \\ &= y_1 \left(-\frac{x\,\mathrm{e}^{x+\ln(x-2)+\ln(x)}\,\mathrm{e}^{-2x}}{x-2}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\frac{\sqrt{x-2}\,\sqrt{x}\,\mathrm{e}^{x}}{\sqrt{x(x-2)}}\right) + c_2 \left(\frac{\sqrt{x-2}\,\sqrt{x}\,\mathrm{e}^{x}}{\sqrt{x(x-2)}} \left(-\frac{x\,\mathrm{e}^{x+\ln(x-2)+\ln(x)}\,\mathrm{e}^{-2x}}{x-2}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$(x^2-2x)\left(\frac{d^2}{dx^2}y(x)\right)+(-x^2+2)\left(\frac{d}{dx}y(x)\right)+(2x-2)\,y(x)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x)=-\frac{2(x-1)y(x)}{x(x-2)}+\frac{(x^2-2)\left(\frac{d}{dx}y(x)\right)}{x(x-2)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x)-\frac{(x^2-2)\left(\frac{d}{dx}y(x)\right)}{x(x-2)}+\frac{2(x-1)y(x)}{x(x-2)}=0$

☐ Check to see if x_0 is a regular singular point

- ∘ Define functions

  $\left[P_2(x)=-\frac{x^2-2}{x(x-2)},P_3(x)=\frac{2(x-1)}{x(x-2)}\right]$

- ∘ $x\cdot P_2(x)$ is analytic at $x=0$

  $\left(x\cdot P_2(x)\right)\Big|_{x=0}=-1$

- ∘ $x^2\cdot P_3(x)$ is analytic at $x=0$

  $\left(x^2\cdot P_3(x)\right)\Big|_{x=0}=0$

- ∘ $x=0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=0$

- Multiply by denominators

  $x(x-2)\left(\frac{d^2}{dx^2}y(x)\right)+(-x^2+2)\left(\frac{d}{dx}y(x)\right)+(2x-2)\,y(x)=0$

- Assume series solution for $y(x)$

  $y(x)=\sum_{k=0}^{\infty}a_kx^{k+r}$

☐ Rewrite ODE with series expansions

- ∘ Convert $x^m\cdot y(x)$ to series expansion for $m=0..1$

  $x^m\cdot y(x)=\sum_{k=0}^{\infty}a_kx^{k+r+m}$

- ∘ Shift index using $k->k-m$

  $x^m\cdot y(x)=\sum_{k=m}^{\infty}a_{k-m}x^{k+r}$

- ∘ Convert $x^m\cdot\left(\frac{d}{dx}y(x)\right)$ to series expansion for $m=0..2$

  $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,x^{k+r-1+m}$

- ∘ Shift index using $k->k+1-m$

  $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,x^{k+r}$

- ∘ Convert $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m=1..2$

  $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,x^{k+r-2+m}$

- ∘ Shift index using $k->k+2-m$

  $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=-2+m}^{\infty}a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$

  Rewrite ODE with series expansions

$$-2a_0r(-2+r)\,x^{-1+r}+(-2a_1(1+r)\,(-1+r)+a_0(1+r)\,(-2+r))\,x^r+\left(\sum_{k=1}^{\infty}(-2a_{k+1}(k+r+\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $-2r(-2+r)=0$
- Values of r that satisfy the indicial equation
  $r\in\{0,2\}$
- Each term must be 0
  $-2a_1(1+r)\,(-1+r)+a_0(1+r)\,(-2+r)=0$
- Each term in the series must be 0, giving the recursion relation
  $a_k(k+r+1)\,(k+r-2)-2k^2a_{k+1}+(-4ra_{k+1}-a_{k-1})\,k-2r^2a_{k+1}-a_{k-1}r+3a_{k-1}+2a_{k+1}=$
- Shift index using $k->k+1$
  $a_{k+1}(k+2+r)\,(k+r-1)-2(k+1)^2\,a_{k+2}+(-4ra_{k+2}-a_k)\,(k+1)-2r^2a_{k+2}-ra_k+3a_k+$
- Recursion relation that defines series solution to ODE
  $a_{k+2}=\frac{k^2a_{k+1}+2kra_{k+1}+r^2a_{k+1}-ka_k+ka_{k+1}-ra_k+ra_{k+1}+2a_k-2a_{k+1}}{2(k^2+2kr+r^2+2k+2r)}$
- Recursion relation for $r=0$
  $a_{k+2}=\frac{k^2a_{k+1}-ka_k+ka_{k+1}+2a_k-2a_{k+1}}{2(k^2+2k)}$
- Series not valid for $r=0$, division by 0 in the recursion relation at $k=0$
  $a_{k+2}=\frac{k^2a_{k+1}-ka_k+ka_{k+1}+2a_k-2a_{k+1}}{2(k^2+2k)}$
- Recursion relation for $r=2$
  $a_{k+2}=\frac{k^2a_{k+1}-ka_k+5ka_{k+1}+4a_{k+1}}{2(k^2+6k+8)}$
- Solution for $r=2$
  $\left[y(x)=\sum_{k=0}^{\infty}a_kx^{k+2},a_{k+2}=\frac{k^2a_{k+1}-ka_k+5ka_{k+1}+4a_{k+1}}{2(k^2+6k+8)},-6a_1=0\right]$

2.1.31 Problem 32

Internal problem ID [9203]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 32
Date solved : `Monday, January 27, 2025 at 05:52:03 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$4x^2y'' + \left(-8x^2+4x\right)y' + \left(4x^2-4x-1\right)y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.105 (sec)

Writing the ode as

$$4x^2y'' + \left(-8x^2+4x\right)y' + \left(4x^2-4x-1\right)y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4x^2 \\ B &= -8x^2+4x \\ C &= 4x^2-4x-1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.56: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-8x^2+4x}{4x^2}\, dx} \\ &= z_1 e^{x - \frac{\ln(x)}{2}} \\ &= z_1 \left(\frac{e^x}{\sqrt{x}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{e^x}{\sqrt{x}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-8x^2+4x}{4x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{2x-\ln(x)}}{(y_1)^2}\, dx \\
&= y_1(x)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{e^x}{\sqrt{x}}\right) + c_2 \left(\frac{e^x}{\sqrt{x}}(x)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$4x^2\left(\frac{d^2}{dx^2}y(x)\right) + (-8x^2+4x)\left(\frac{d}{dx}y(x)\right) + (4x^2-4x-1)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{(4x^2-4x-1)y(x)}{4x^2} + \frac{(2x-1)\left(\frac{d}{dx}y(x)\right)}{x}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x) - \frac{(2x-1)\left(\frac{d}{dx}y(x)\right)}{x} + \frac{(4x^2-4x-1)y(x)}{4x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  - Define functions

    $\left[P_2(x) = -\frac{2x-1}{x}, P_3(x) = \frac{4x^2-4x-1}{4x^2}\right]$

  - $x \cdot P_2(x)$ is analytic at $x = 0$

    $(x \cdot P_2(x))\Big|_{x=0} = 1$

  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $(x^2 \cdot P_3(x))\Big|_{x=0} = -\frac{1}{4}$

  - $x = 0$is a regular singular point

    Check to see if $x_0 = 0$ is a regular singular point

    $x_0 = 0$

- Multiply by denominators

  $4x^2\left(\frac{d^2}{dx^2}y(x)\right) - 4x(2x-1)\left(\frac{d}{dx}y(x)\right) + (4x^2-4x-1)\,y(x) = 0$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

  - Convert $x^m \cdot y(x)$ to series expansion for $m = 0..2$

    $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- Shift index using $k->k-m$

  $x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- Convert $x^m \cdot \left(\frac{d}{dx} y(x)\right)$ to series expansion for $m = 1..2$

  $x^m \cdot \left(\frac{d}{dx} y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1+m}$

- Shift index using $k->k+1-m$

  $x^m \cdot \left(\frac{d}{dx} y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$

- Convert $x^2 \cdot \left(\frac{d^2}{dx^2} y(x)\right)$ to series expansion

  $x^2 \cdot \left(\frac{d^2}{dx^2} y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(1+2r)(-1+2r)\, x^r + (a_1(3+2r)(1+2r) - 4a_0(1+2r))\, x^{1+r} + \left(\sum_{k=2}^{\infty} (a_k(2k+2r+1)(2k+2\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(1+2r)(-1+2r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \left\{-\frac{1}{2}, \frac{1}{2}\right\}$

- Each term must be 0

  $a_1(3+2r)(1+2r) - 4a_0(1+2r) = 0$

- Solve for the dependent coefficient(s)

  $a_1 = \frac{4a_0}{3+2r}$

- Each term in the series must be 0, giving the recursion relation

  $a_k(4k^2 + 8kr + 4r^2 - 1) + (-8k - 8r + 4)\, a_{k-1} + 4a_{k-2} = 0$

- Shift index using $k->k+2$

  $a_{k+2}\left(4(k+2)^2 + 8(k+2)\, r + 4r^2 - 1\right) + (-8k - 12 - 8r)\, a_{k+1} + 4a_k = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+2} = \frac{4(2ka_{k+1} + 2ra_{k+1} - a_k + 3a_{k+1})}{4k^2 + 8kr + 4r^2 + 16k + 16r + 15}$

- Recursion relation for $r = -\frac{1}{2}$

  $a_{k+2} = \frac{4(2ka_{k+1} - a_k + 2a_{k+1})}{4k^2 + 12k + 8}$

- Solution for $r = -\frac{1}{2}$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k-\frac{1}{2}}, a_{k+2} = \frac{4(2ka_{k+1} - a_k + 2a_{k+1})}{4k^2 + 12k + 8}, a_1 = 2a_0\right]$

- Recursion relation for $r = \frac{1}{2}$

  $a_{k+2} = \frac{4(2ka_{k+1} - a_k + 4a_{k+1})}{4k^2 + 20k + 24}$

- Solution for $r = \frac{1}{2}$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}, a_{k+2} = \frac{4(2ka_{k+1} - a_k + 4a_{k+1})}{4k^2 + 20k + 24}, a_1 = a_0\right]$

- Combine solutions and rename parameters

  $\left[y(x) = \left(\sum_{k=0}^{\infty} a_k x^{k-\frac{1}{2}}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{2}}\right), a_{k+2} = \frac{4(2ka_{k+1} - a_k + 2a_{k+1})}{4k^2 + 12k + 8}, a_1 = 2a_0, b_{k+2} = \frac{4(2kb_{k+1} - b_k + 4b_{k+1})}{4k^2 + 20k + 24}\right.$

2.1.32 Problem 33

Internal problem ID [9204]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 33
Date solved : `Monday, January 27, 2025 at 05:52:03 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$y'' + 4xy' + \left(4x^2 + 2\right) y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.055 (sec)

Writing the ode as

$$y'' + 4xy' + \left(4x^2 + 2\right) y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 4x \\ C &= 4x^2 + 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.58: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{4x}{1}\, dx} \\ &= z_1 e^{-x^2} \\ &= z_1 \left(\mathrm{e}^{-x^2}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-x^2}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{4x}{1}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-2x^2}}{(y_1)^2}\, dx \\ &= y_1(x) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\mathrm{e}^{-x^2}\right) + c_2 \left(\mathrm{e}^{-x^2}(x)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve
$\frac{d^2}{dx^2}y(x) + 4x\left(\frac{d}{dx}y(x)\right) + (4x^2+2)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2
  $\frac{d^2}{dx^2}y(x)$
- Assume series solution for $y(x)$
  $y(x) = \sum_{k=0}^{\infty} a_k x^k$

☐ Rewrite ODE with series expansions

- ◦ Convert $x^m \cdot y(x)$ to series expansion for $m = 0..2$
  $x^m \cdot y(x) = \sum_{k=\max(0,-m)}^{\infty} a_k x^{k+m}$
- ◦ Shift index using $k- >k-m$
  $x^m \cdot y(x) = \sum_{k=\max(0,-m)+m}^{\infty} a_{k-m} x^k$
- ◦ Convert $x \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion
  $x \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k k\, x^k$
- ◦ Convert $\frac{d^2}{dx^2}y(x)$ to series expansion
  $\frac{d^2}{dx^2}y(x) = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$
- ◦ Shift index using $k- >k+2$
  $\frac{d^2}{dx^2}y(x) = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$

Rewrite ODE with series expansions
$2a_2 + 2a_0 + (6a_3 + 6a_1)\, x + \left(\sum_{k=2}^{\infty} \left(a_{k+2}(k+2)\,(k+1) + 2a_k(2k+1) + 4a_{k-2}\right) x^k\right) = 0$

- The coefficients of each power of x must be 0
  $[2a_2 + 2a_0 = 0, 6a_3 + 6a_1 = 0]$
- Solve for the dependent coefficient(s)
  $\{a_2 = -a_0, a_3 = -a_1\}$
- Each term in the series must be 0, giving the recursion relation
  $(k^2 + 3k + 2)\, a_{k+2} + 4a_k k + 2a_k + 4a_{k-2} = 0$

- Shift index using $k- >k+2$

  $$\left((k+2)^2+3k+8\right)a_{k+4}+4a_{k+2}(k+2)+2a_{k+2}+4a_k=0$$

- Recursion relation that defines the series solution to the ODE

  $$\left[y(x)=\sum_{k=0}^{\infty}a_k x^k, a_{k+4}=-\frac{2(2ka_{k+2}+2a_k+5a_{k+2})}{k^2+7k+12}, a_2=-a_0, a_3=-a_1\right]$$

2.1.33 Problem 34

Internal problem ID [9205]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 34
Date solved : `Monday, January 27, 2025 at 05:52:04 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$(2x+1)\,y''-2y'-(2x+3)\,y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.224 (sec)

Writing the ode as

$$(2x+1)\,y''-2y'+(-2x-3)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2x+1\\ B &= -2 \\ C &= -2x-3 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{4x^2+8x+6}{(2x+1)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 4x^2+8x+6\\ t &= (2x+1)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{4x^2+8x+6}{(2x+1)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.60: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (2x+1)^2$. There is a pole at $x = -\frac{1}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = 1 + \frac{3}{4\left(x + \frac{1}{2}\right)^2} + \frac{1}{x + \frac{1}{2}}$$

For the pole at $x = -\frac{1}{2}$ let b be the coefficient of $\frac{1}{\left(x+\frac{1}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx 1 + \frac{1}{2x} - \frac{1}{4x^3} + \frac{11}{32x^4} - \frac{21}{64x^5} + \frac{15}{64x^6} - \frac{3}{32x^7} - \frac{117}{2048x^8} + \ldots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = 1$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= 1 \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = 1$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{4x^2 + 8x + 6}{4x^2 + 4x + 1} \\ &= Q + \frac{R}{4x^2 + 4x + 1} \\ &= (1) + \left(\frac{4x + 5}{4x^2 + 4x + 1}\right) \\ &= 1 + \frac{4x + 5}{4x^2 + 4x + 1} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is 4. Dividing this by leading coefficient in t which is 4 gives 1. Now b can be found.

$$\begin{aligned} b &= (1) - (0) \\ &= 1 \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= 1 \\ \alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{1}{1} - 0\right) &&= \frac{1}{2} \\ \alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{1}{1} - 0\right) &&= -\frac{1}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{4x^2+8x+6}{(2x+1)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
$-\frac{1}{2}$	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	1	$\frac{1}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -\frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^- - (\alpha_{c_1}^-) \\ &= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= -\frac{1}{2\left(x+\frac{1}{2}\right)} + (-)(1) \\ &= -\frac{1}{2\left(x+\frac{1}{2}\right)} - 1 \\ &= -\frac{2(x+1)}{2x+1} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{2\left(x+\frac{1}{2}\right)} - 1\right)(0) + \left(\left(\frac{1}{2\left(x+\frac{1}{2}\right)^2}\right) + \left(-\frac{1}{2\left(x+\frac{1}{2}\right)} - 1\right)^2 - \left(\frac{4x^2+8x+6}{(2x+1)^2}\right) \right) = 0$$

$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(-\frac{1}{2\left(x+\frac{1}{2}\right)}-1\right)dx} \\
&= \frac{\mathrm{e}^{-x}}{\sqrt{2x+1}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-2}{2x+1}\, dx} \\
&= z_1 e^{\frac{\ln(2x+1)}{2}} \\
&= z_1 \left(\sqrt{2x+1}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{-x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-2}{2x+1}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{\ln(2x+1)}}{(y_1)^2}\, dx \\
&= y_1 \left(x\, \mathrm{e}^{2x}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-x}\right) + c_2 \left(\mathrm{e}^{-x}\left(x\, \mathrm{e}^{2x}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$(2x+1)\left(\frac{d^2}{dx^2}y(x)\right) - 2\frac{d}{dx}y(x) - (2x+3)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = \frac{(2x+3)y(x)}{2x+1} + \frac{2\left(\frac{d}{dx}y(x)\right)}{2x+1}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

$\frac{d^2}{dx^2}y(x) - \frac{2\left(\frac{d}{dx}y(x)\right)}{2x+1} - \frac{(2x+3)y(x)}{2x+1} = 0$

- ☐ Check to see if $x_0 = -\frac{1}{2}$ is a regular singular point
  - ◦ Define functions
    $\left[P_2(x) = -\frac{2}{2x+1}, P_3(x) = -\frac{2x+3}{2x+1}\right]$
  - ◦ $\left(x+\frac{1}{2}\right) \cdot P_2(x)$ is analytic at $x = -\frac{1}{2}$
    $\left(\left(x+\frac{1}{2}\right) \cdot P_2(x)\right)\Big|_{x=-\frac{1}{2}} = -1$
  - ◦ $\left(x+\frac{1}{2}\right)^2 \cdot P_3(x)$ is analytic at $x = -\frac{1}{2}$
    $\left(\left(x+\frac{1}{2}\right)^2 \cdot P_3(x)\right)\Big|_{x=-\frac{1}{2}} = 0$
  - ◦ $x = -\frac{1}{2}$is a regular singular point
    Check to see if $x_0 = -\frac{1}{2}$ is a regular singular point
    $x_0 = -\frac{1}{2}$
- • Multiply by denominators
  $(2x+1)\left(\frac{d^2}{dx^2}y(x)\right) - 2\frac{d}{dx}y(x) + (-2x-3)\,y(x) = 0$
- • Change variables using $x = u - \frac{1}{2}$ so that the regular singular point is at $u = 0$

CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$xy'' - (2x + 2) y' + (x + 2) y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.129 (sec)

Writing the ode as

$$xy'' + (-2x - 2) y' + (x + 2) y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x \\ B &= -2x - 2 \\ C &= x + 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{2}{x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 2 \\ t &= x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{2}{x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.62: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{2}{x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -1 \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{2}{x^2}$$

Since the gcd$(s,t) = 1$. This gives $b = 2$. Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= 0\\ \alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = 2\\ \alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -1\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{2}{x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	2	-1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	2	-1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -1$ then

$$\begin{aligned}d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right)\\ &= -1 - (-1)\\ &= 0\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + (-)[\sqrt{r}]_\infty\\ &= -\frac{1}{x} + (-)(0)\\ &= -\frac{1}{x}\\ &= -\frac{1}{x}\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned}(0) + 2\left(-\frac{1}{x}\right)(0) + \left(\left(\frac{1}{x^2}\right) + \left(-\frac{1}{x}\right)^2 - \left(\frac{2}{x^2}\right)\right) &= 0\\ 0 &= 0\end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int -\frac{1}{x} dx} \\
&= \frac{1}{x}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-2x-2}{x} \, dx} \\
&= z_1 e^{x+\ln(x)} \\
&= z_1 (x \, \mathrm{e}^{x})
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-2x-2}{x} \, dx}}{(y_1)^2} \, dx \\
&= y_1 \int \frac{e^{2x+2\ln(x)}}{(y_1)^2} \, dx \\
&= y_1 \left(\frac{x \, \mathrm{e}^{2x+2\ln(x)} \mathrm{e}^{-2x}}{3} \right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(\mathrm{e}^{x}) + c_2 \left(\mathrm{e}^{x} \left(\frac{x \, \mathrm{e}^{2x+2\ln(x)} \mathrm{e}^{-2x}}{3} \right) \right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

2.1.35 Problem 36

Internal problem ID [9207]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 36
Date solved : `Monday, January 27, 2025 at 05:52:05 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' - 2xy' + (x^2 + 2)\, y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.126 (sec)

Writing the ode as

$$x^2y'' - 2xy' + (x^2 + 2)\, y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -2x \\ C &= x^2 + 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.64: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-2x}{x^2}\, dx} \\ &= z_1 e^{\ln(x)} \\ &= z_1(x) \end{aligned}$$

Which simplifies to

$$y_1 = x\cos(x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-2x}{x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{2\ln(x)}}{(y_1)^2}\,dx \\
&= y_1(\tan(x))
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(x\cos(x)) + c_2(x\cos(x)(\tan(x)))
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2\left(\frac{d^2}{dx^2}y(x)\right) - 2x\left(\frac{d}{dx}y(x)\right) + (x^2+2)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{(x^2+2)y(x)}{x^2} + \frac{2\left(\frac{d}{dx}y(x)\right)}{x}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x) - \frac{2\left(\frac{d}{dx}y(x)\right)}{x} + \frac{(x^2+2)y(x)}{x^2} = 0$

- ☐ Check to see if $x_0 = 0$ is a regular singular point
  - Define functions

    $\left[P_2(x) = -\frac{2}{x}, P_3(x) = \frac{x^2+2}{x^2}\right]$
  - $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left.(x \cdot P_2(x))\right|_{x=0} = -2$
  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $\left.(x^2 \cdot P_3(x))\right|_{x=0} = 2$
  - $x = 0$is a regular singular point

    Check to see if $x_0 = 0$ is a regular singular point

    $x_0 = 0$

- Multiply by denominators

  $x^2\left(\frac{d^2}{dx^2}y(x)\right) - 2x\left(\frac{d}{dx}y(x)\right) + (x^2+2)\,y(x) = 0$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

- ☐ Rewrite ODE with series expansions
  - Convert $x^m \cdot y(x)$ to series expansion for $m = 0..2$

    $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$
  - Shift index using $k- >k - m$

$$x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$$

- Convert $x \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion

$$x \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r}$$

- Convert $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

$$x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0(-1+r)\,(-2+r)\, x^r + a_1 r(-1+r)\, x^{1+r} + \left(\sum_{k=2}^{\infty} (a_k(k+r-1)\,(k+r-2) + a_{k-2})\, x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
$(-1+r)\,(-2+r) = 0$
- Values of r that satisfy the indicial equation
$r \in \{1, 2\}$
- Each term must be 0
$a_1 r(-1+r) = 0$
- Solve for the dependent coefficient(s)
$a_1 = 0$
- Each term in the series must be 0, giving the recursion relation
$a_k(k+r-1)\,(k+r-2) + a_{k-2} = 0$
- Shift index using $k- >k+2$
$a_{k+2}(k+1+r)\,(k+r) + a_k = 0$
- Recursion relation that defines series solution to ODE
$a_{k+2} = -\frac{a_k}{(k+1+r)(k+r)}$

2.1.36 Problem 38

Internal problem ID [9208]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 38
Date solved : `Monday, January 27, 2025 at 05:52:06 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$4x^2y'' - 4xy' + \left(-16x^2+3\right)y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.089 (sec)

Writing the ode as

$$4x^2y'' - 4xy' + \left(-16x^2+3\right)y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4x^2 \\ B &= -4x \\ C &= -16x^2+3 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{4}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 4 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 4z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.66: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 4$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-2x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-4x}{4x^2}\, dx} \\ &= z_1 e^{\frac{\ln(x)}{2}} \\ &= z_1\left(\sqrt{x}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \sqrt{x}\,\mathrm{e}^{-2x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-4x}{4x^2}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{\ln(x)}}{(y_1)^2}\,dx \\ &= y_1 \left(\frac{e^{4x}}{4}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\sqrt{x}\, e^{-2x}\right) + c_2 \left(\sqrt{x}\, e^{-2x} \left(\frac{e^{4x}}{4}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve
$4x^2 \left(\frac{d^2}{dx^2}y(x)\right) - 4x\left(\frac{d}{dx}y(x)\right) + (-16x^2+3)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2
  $\frac{d^2}{dx^2}y(x)$
- Isolate 2nd derivative
  $\frac{d^2}{dx^2}y(x) = \frac{(16x^2-3)y(x)}{4x^2} + \frac{\frac{d}{dx}y(x)}{x}$
- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin
  $\frac{d^2}{dx^2}y(x) - \frac{\frac{d}{dx}y(x)}{x} - \frac{(16x^2-3)y(x)}{4x^2} = 0$
- □ Check to see if $x_0 = 0$ is a regular singular point
  - Define functions
    $\left[P_2(x) = -\frac{1}{x}, P_3(x) = -\frac{16x^2-3}{4x^2}\right]$
  - $x \cdot P_2(x)$ is analytic at $x = 0$
    $\left.(x \cdot P_2(x))\right|_{x=0} = -1$
  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$
    $\left.(x^2 \cdot P_3(x))\right|_{x=0} = \frac{3}{4}$
  - $x = 0$is a regular singular point
    Check to see if $x_0 = 0$ is a regular singular point
    $x_0 = 0$
- Multiply by denominators
  $4x^2 \left(\frac{d^2}{dx^2}y(x)\right) - 4x\left(\frac{d}{dx}y(x)\right) + (-16x^2+3)\,y(x) = 0$
- Assume series solution for $y(x)$
  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$
- □ Rewrite ODE with series expansions
  - Convert $x^m \cdot y(x)$ to series expansion for $m = 0..2$
    $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- Shift index using $k- >k-m$

  $x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- Convert $x \cdot \left(\frac{d}{dx} y(x)\right)$ to series expansion

  $x \cdot \left(\frac{d}{dx} y(x)\right) = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r}$

- Convert $x^2 \cdot \left(\frac{d^2}{dx^2} y(x)\right)$ to series expansion

  $x^2 \cdot \left(\frac{d^2}{dx^2} y(x)\right) = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(-1+2r)\,(-3+2r)\, x^r + a_1(1+2r)\,(-1+2r)\, x^{1+r} + \left(\sum_{k=2}^{\infty} (a_k(2k+2r-1)\,(2k+2r-3) - 16a\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-1+2r)\,(-3+2r) = 0$
- Values of r that satisfy the indicial equation

  $r \in \left\{\frac{1}{2}, \frac{3}{2}\right\}$
- Each term must be 0

  $a_1(1+2r)\,(-1+2r) = 0$
- Solve for the dependent coefficient(s)

  $a_1 = 0$
- Each term in the series must be 0, giving the recursion relation

  $4\left(k+r-\frac{1}{2}\right)\left(k+r-\frac{3}{2}\right) a_k - 16a_{k-2} = 0$
- Shift index using $k- >k+2$

  $4\left(k+\frac{3}{2}+r\right)\left(k+\frac{1}{2}+r\right) a_{k+2} - 16a_k = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+2} = \frac{16a_k}{(2k+3+2r)(2k+1+2r)}$
- Recursion relation for $r = \frac{1}{2}$

  $a_{k+2} = \frac{16a_k}{(2k+4)(2k+2)}$
- Solution for $r = \frac{1}{2}$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}, a_{k+2} = \frac{16a_k}{(2k+4)(2k+2)}, a_1 = 0\right]$
- Recursion relation for $r = \frac{3}{2}$

  $a_{k+2} = \frac{16a_k}{(2k+6)(2k+4)}$
- Solution for $r = \frac{3}{2}$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+\frac{3}{2}}, a_{k+2} = \frac{16a_k}{(2k+6)(2k+4)}, a_1 = 0\right]$
- Combine solutions and rename parameters

  $\left[y(x) = \left(\sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{3}{2}}\right), a_{k+2} = \frac{16a_k}{(2k+4)(2k+2)}, a_1 = 0, b_{k+2} = \frac{16b_k}{(2k+6)(2k+4)}, b_1 = 0\right]$

2.1.37 Problem 39

Internal problem ID [9209]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 39
Date solved : `Monday, January 27, 2025 at 05:52:06 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$4x^2y'' - 4xy' + \left(4x^2+3\right)y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.142 (sec)

Writing the ode as

$$4x^2y'' - 4xy' + \left(4x^2+3\right)y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4x^2 \\ B &= -4x \\ C &= 4x^2+3 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.68: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-4x}{4x^2}\, dx} \\ &= z_1 e^{\frac{\ln(x)}{2}} \\ &= z_1\left(\sqrt{x}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \sqrt{x}\, \cos(x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-4x}{4x^2} dx}}{(y_1)^2} dx \\ &= y_1 \int \frac{e^{\ln(x)}}{(y_1)^2} dx \\ &= y_1(\tan(x)) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\sqrt{x}\,\cos(x)\right) + c_2\left(\sqrt{x}\,\cos(x)\,(\tan(x))\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve
$4x^2\left(\frac{d^2}{dx^2}y(x)\right) - 4x\left(\frac{d}{dx}y(x)\right) + (4x^2+3)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2
  $\frac{d^2}{dx^2}y(x)$
- Isolate 2nd derivative

    $\left[P_2(x) = -\frac{1}{x}, P_3(x) = \frac{4x^2+3}{4x^2}\right]$
  - $x \cdot P_2(x)$ is analytic at $x = 0$
    $\left.(x \cdot P_2(x))\right|_{x=0} = -1$
  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$
    $\left.(x^2 \cdot P_3(x))\right|_{x=0} = \frac{3}{4}$
  - $x = 0$is a regular singular point
    Check to see if $x_0 = 0$ is a regular singular point
    $x_0 = 0$
- Multiply by denominators
  $4x^2\left(\frac{d^2}{dx^2}y(x)\right) - 4x\left(\frac{d}{dx}y(x)\right) + (4x^2+3)\,y(x) = 0$
- Assume series solution for $y(x)$
  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$
- □ Rewrite ODE with series expansions
  - Convert $x^m \cdot y(x)$ to series expansion for $m = 0..2$
    $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$
  - Shift index using $k- >k - m$

$x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- Convert $x \cdot \left(\frac{d}{dx} y(x)\right)$ to series expansion

  $x \cdot \left(\frac{d}{dx} y(x)\right) = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r}$

- Convert $x^2 \cdot \left(\frac{d^2}{dx^2} y(x)\right)$ to series expansion

  $x^2 \cdot \left(\frac{d^2}{dx^2} y(x)\right) = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(-1+2r)\,(-3+2r)\, x^r + a_1(1+2r)\,(-1+2r)\, x^{1+r} + \left(\sum_{k=2}^{\infty} (a_k(2k+2r-1)\,(2k+2r-3) + 4\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-1+2r)\,(-3+2r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \left\{\frac{1}{2}, \frac{3}{2}\right\}$

- Each term must be 0

  $a_1(1+2r)\,(-1+2r) = 0$

- Solve for the dependent coefficient(s)

  $a_1 = 0$

- Each term in the series must be 0, giving the recursion relation

  $4\left(k+r-\frac{1}{2}\right)\left(k+r-\frac{3}{2}\right) a_k + 4a_{k-2} = 0$

- Shift index using $k- >k+2$

  $4\left(k+\frac{3}{2}+r\right)\left(k+\frac{1}{2}+r\right) a_{k+2} + 4a_k = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{4a_k}{(2k+3+2r)(2k+1+2r)}$

- Recursion relation for $r = \frac{1}{2}$

  $a_{k+2} = -\frac{4a_k}{(2k+4)(2k+2)}$

- Solution for $r = \frac{1}{2}$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}, a_{k+2} = -\frac{4a_k}{(2k+4)(2k+2)}, a_1 = 0\right]$

- Recursion relation for $r = \frac{3}{2}$

  $a_{k+2} = -\frac{4a_k}{(2k+6)(2k+4)}$

- Solution for $r = \frac{3}{2}$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+\frac{3}{2}}, a_{k+2} = -\frac{4a_k}{(2k+6)(2k+4)}, a_1 = 0\right]$

- Combine solutions and rename parameters

  $\left[y(x) = \left(\sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{3}{2}}\right), a_{k+2} = -\frac{4a_k}{(2k+4)(2k+2)}, a_1 = 0, b_{k+2} = -\frac{4b_k}{(2k+6)(2k+4)}, b_1 =\right.$

2.1.38 Problem 40

Internal problem ID [9210]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 40
Date solved : `Monday, January 27, 2025 at 05:52:07 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' - 2xy' - \left(x^2-2\right)y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.072 (sec)

Writing the ode as

$$x^2y'' - 2xy' + \left(-x^2+2\right)y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -2x \\ C &= -x^2+2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.70: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-2x}{x^2}\, dx} \\ &= z_1 e^{\ln(x)} \\ &= z_1(x) \end{aligned}$$

Which simplifies to

$$y_1 = x\,\mathrm{e}^{-x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-2x}{x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{2\ln(x)}}{(y_1)^2}\, dx \\
&= y_1 \left(\frac{e^{2x}}{2}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(x\, e^{-x}\right) + c_2 \left(x\, e^{-x} \left(\frac{e^{2x}}{2}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve
$x^2\left(\frac{d^2}{dx^2}y(x)\right) - 2x\left(\frac{d}{dx}y(x)\right) - (x^2-2)\, y(x) = 0$

- Highest derivative means the order of the ODE is 2
$\frac{d^2}{dx^2}y(x)$
- Isolate 2nd derivative
$\frac{d^2}{dx^2}y(x) = \frac{(x^2-2)y(x)}{x^2} + \frac{2\left(\frac{d}{dx}y(x)\right)}{x}$
- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin
$\frac{d^2}{dx^2}y(x) - \frac{2\left(\frac{d}{dx}y(x)\right)}{x} - \frac{(x^2-2)y(x)}{x^2} = 0$

☐ Check to see if $x_0 = 0$ is a regular singular point
  - Define functions
  $\left[P_2(x) = -\frac{2}{x}, P_3(x) = -\frac{x^2-2}{x^2}\right]$
  - $x \cdot P_2(x)$ is analytic at $x = 0$
  $\left.(x \cdot P_2(x))\right|_{x=0} = -2$
  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$
  $\left.(x^2 \cdot P_3(x))\right|_{x=0} = 2$
  - $x = 0$is a regular singular point
  Check to see if $x_0 = 0$ is a regular singular point
  $x_0 = 0$
- Multiply by denominators
$x^2\left(\frac{d^2}{dx^2}y(x)\right) - 2x\left(\frac{d}{dx}y(x)\right) + (-x^2+2)\, y(x) = 0$
- Assume series solution for $y(x)$
$y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions
  - Convert $x^m \cdot y(x)$ to series expansion for $m = 0..2$

$x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- Shift index using $k- >k-m$

  $x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- Convert $x \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion

  $x \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r}$

- Convert $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

  $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(-1+r)\,(-2+r)\, x^r + a_1 r(-1+r)\, x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(k+r-1)\,(k+r-2) - a_{k-2}\right) x^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-1+r)\,(-2+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{1, 2\}$

- Each term must be 0

  $a_1 r(-1+r) = 0$

- Solve for the dependent coefficient(s)

  $a_1 = 0$

- Each term in the series must be 0, giving the recursion relation

  $a_k(k+r-1)\,(k+r-2) - a_{k-2} = 0$

- Shift index using $k- >k+2$

  $a_{k+2}(k+1+r)\,(k+r) - a_k = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+2} = \frac{a_k}{(k+1+r)(k+r)}$

- Recursion relation for $r = 1$

  $a_{k+2} = \frac{a_k}{(k+2)(k+1)}$

- Solution for $r = 1$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+1}, a_{k+2} = \frac{a_k}{(k+2)(k+1)}, a_1 = 0\right]$

- Recursion relation for $r = 2$

  $a_{k+2} = \frac{a_k}{(k+3)(k+2)}$

- Solution for $r = 2$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+2}, a_{k+2} = \frac{a_k}{(k+3)(k+2)}, a_1 = 0\right]$

- Combine solutions and rename parameters

  $\left[y(x) = \left(\sum_{k=0}^{\infty} a_k x^{k+1}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+2}\right), a_{k+2} = \frac{a_k}{(k+2)(k+1)}, a_1 = 0, b_{k+2} = \frac{b_k}{(k+3)(k+2)}, b_1 = 0\right]$

2.1.39 Problem 41

Internal problem ID [9211]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 41
Date solved : `Monday, January 27, 2025 at 05:52:07 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' - 2x(x+1)\,y' + \left(x^2+2x+2\right)y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.077 (sec)

Writing the ode as

$$x^2y'' + \left(-2x^2-2x\right)y' + \left(x^2+2x+2\right)y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -2x^2-2x \\ C &= x^2+2x+2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.72: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-2x^2-2x}{x^2}\, dx} \\ &= z_1 e^{x+\ln(x)} \\ &= z_1 (x\, \mathrm{e}^{x}) \end{aligned}$$

Which simplifies to

$$y_1 = x\, \mathrm{e}^{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-2x^2-2x}{x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{2x+2\ln(x)}}{(y_1)^2}\,dx \\
&= y_1(x)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(x\,\mathrm{e}^{x}) + c_2(x\,\mathrm{e}^{x}(x))
\end{aligned}$$

Will add steps showing solving for IC soon.

2.1.40 Problem 42

Internal problem ID [9212]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 42
Date solved : `Monday, January 27, 2025 at 05:52:08 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' - 2x(x+2)\,y' + \left(x^2+4x+6\right)y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.097 (sec)

Writing the ode as

$$x^2y'' + \left(-2x^2-4x\right)y' + \left(x^2+4x+6\right)y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -2x^2-4x \\ C &= x^2+4x+6 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$s = 0$$
$$t = 1$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.74: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2} \frac{-2x^2-4x}{x^2}\, dx} \\ &= z_1 e^{x+2\ln(x)} \\ &= z_1 \left(x^2 \mathrm{e}^x\right) \end{aligned}$$

Which simplifies to

$$y_1 = x^2 \mathrm{e}^x$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-2x^2-4x}{x^2} dx}}{(y_1)^2} dx \\
&= y_1 \int \frac{e^{2x+4\ln(x)}}{(y_1)^2} dx \\
&= y_1(x)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 (x^2 e^x) + c_2 (x^2 e^x (x))
\end{aligned}$$

Will add steps showing solving for IC soon.

  $x^m \cdot \left(\frac{d}{dx} y(x)\right) = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r-1+m}$

- Shift index using $k- > k+1-m$

  $x^m \cdot \left(\frac{d}{dx} y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$

- Convert $x^2 \cdot \left(\frac{d^2}{dx^2} y(x)\right)$ to series expansion

  $x^2 \cdot \left(\frac{d^2}{dx^2} y(x)\right) = \sum_{k=0}^{\infty} a_k (k+r)(k+r-1)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(-2+r)(-3+r)\, x^r + (a_1(-1+r)(-2+r) - 2a_0(-2+r))\, x^{1+r} + \left(\sum_{k=2}^{\infty} (a_k(k+r-2)(k+r-\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-2+r)(-3+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{2, 3\}$

- Each term must be 0

  $a_1(-1+r)(-2+r) - 2a_0(-2+r) = 0$

- Solve for the dependent coefficient(s)

  $a_1 = \frac{2a_0}{-1+r}$

- Each term in the series must be 0, giving the recursion relation

  $a_k(k+r-2)(k+r-3) - 2a_{k-1}k - 2a_{k-1}r + a_{k-2} + 6a_{k-1} = 0$

- Shift index using $k- > k+2$

  $a_{k+2}(k+r)(k+r-1) - 2a_{k+1}(k+2) - 2a_{k+1}r + a_k + 6a_{k+1} = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+2} = \frac{2k a_{k+1} + 2a_{k+1} r - a_k - 2a_{k+1}}{(k+r)(k+r-1)}$

- Recursion relation for $r = 2$

  $a_{k+2} = \frac{2k a_{k+1} - a_k + 2a_{k+1}}{(k+2)(k+1)}$

- Solution for $r = 2$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+2}, a_{k+2} = \frac{2k a_{k+1} - a_k + 2a_{k+1}}{(k+2)(k+1)}, a_1 = 2a_0\right]$

- Recursion relation for $r = 3$

  $a_{k+2} = \frac{2k a_{k+1} - a_k + 4a_{k+1}}{(k+3)(k+2)}$

- Solution for $r = 3$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+3}, a_{k+2} = \frac{2k a_{k+1} - a_k + 4a_{k+1}}{(k+3)(k+2)}, a_1 = a_0\right]$

- Combine solutions and rename parameters

  $\left[y(x) = \left(\sum_{k=0}^{\infty} a_k x^{k+2}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+3}\right), a_{k+2} = \frac{2k a_{k+1} - a_k + 2a_{k+1}}{(k+2)(k+1)}, a_1 = 2a_0, b_{k+2} = \frac{2k b_{k+1} - b_k + 4b_{k+1}}{(k+3)(k+2)}, b_1\right.$

2.1.41 Problem 43

Internal problem ID [9213]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 43
Date solved : `Monday, January 27, 2025 at 05:52:08 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' - 4xy' + \left(x^2+6\right)y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.137 (sec)

Writing the ode as

$$x^2y'' - 4xy' + \left(x^2+6\right)y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -4x \\ C &= x^2+6 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.76: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-4x}{x^2}\, dx} \\ &= z_1 e^{2\ln(x)} \\ &= z_1\left(x^2\right) \end{aligned}$$

Which simplifies to

$$y_1 = x^2 \cos(x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-4x}{x^2}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{4\ln(x)}}{(y_1)^2}\,dx \\ &= y_1(\tan(x)) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(x^2\cos(x)\right) + c_2\left(x^2\cos(x)(\tan(x))\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve
$x^2\left(\frac{d^2}{dx^2}y(x)\right) - 4x\left(\frac{d}{dx}y(x)\right) + (x^2+6)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2
  $\frac{d^2}{dx^2}y(x)$
- Isolate 2nd derivative
  $\frac{d^2}{dx^2}y(x) = -\frac{(x^2+6)y(x)}{x^2} + \frac{4\left(\frac{d}{dx}y(x)\right)}{x}$
- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea
  $\frac{d^2}{dx^2}y(x) - \frac{4\left(\frac{d}{dx}y(x)\right)}{x} + \frac{(x^2+6)y(x)}{x^2} = 0$
- □ Check to see if $x_0 = 0$ is a regular singular point
  - Define functions
    $\left[P_2(x) = -\frac{4}{x}, P_3(x) = \frac{x^2+6}{x^2}\right]$
  - $x \cdot P_2(x)$ is analytic at $x = 0$
    $\left.(x \cdot P_2(x))\right|_{x=0} = -4$
  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$
    $\left.(x^2 \cdot P_3(x))\right|_{x=0} = 6$
  - $x = 0$is a regular singular point
    Check to see if $x_0 = 0$ is a regular singular point
    $x_0 = 0$
- Multiply by denominators
  $x^2\left(\frac{d^2}{dx^2}y(x)\right) - 4x\left(\frac{d}{dx}y(x)\right) + (x^2+6)\,y(x) = 0$
- Assume series solution for $y(x)$
  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$
- □ Rewrite ODE with series expansions
  - Convert $x^m \cdot y(x)$ to series expansion for $m = 0..2$
    $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$
  - Shift index using $k- >k - m$

$x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- Convert $x \cdot \left(\frac{d}{dx} y(x)\right)$ to series expansion

  $x \cdot \left(\frac{d}{dx} y(x)\right) = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r}$

- Convert $x^2 \cdot \left(\frac{d^2}{dx^2} y(x)\right)$ to series expansion

  $x^2 \cdot \left(\frac{d^2}{dx^2} y(x)\right) = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(-2+r)\,(-3+r)\,x^r + a_1(-1+r)\,(-2+r)\,x^{1+r} + \left(\sum_{k=2}^{\infty} (a_k(k+r-2)\,(k+r-3) + a_{k-2})\, x^{k}\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-2+r)\,(-3+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{2, 3\}$

- Each term must be 0

  $a_1(-1+r)\,(-2+r) = 0$

- Solve for the dependent coefficient(s)

  $a_1 = 0$

- Each term in the series must be 0, giving the recursion relation

  $a_k(k+r-2)\,(k+r-3) + a_{k-2} = 0$

- Shift index using $k- >k+2$

  $a_{k+2}(k+r)\,(k+r-1) + a_k = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{a_k}{(k+r)(k+r-1)}$

- Recursion relation for $r = 2$

  $a_{k+2} = -\frac{a_k}{(k+2)(k+1)}$

- Solution for $r = 2$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+2}, a_{k+2} = -\frac{a_k}{(k+2)(k+1)}, a_1 = 0\right]$

- Recursion relation for $r = 3$

  $a_{k+2} = -\frac{a_k}{(k+3)(k+2)}$

- Solution for $r = 3$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+3}, a_{k+2} = -\frac{a_k}{(k+3)(k+2)}, a_1 = 0\right]$

- Combine solutions and rename parameters

  $\left[y(x) = \left(\sum_{k=0}^{\infty} a_k x^{k+2}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+3}\right), a_{k+2} = -\frac{a_k}{(k+2)(k+1)}, a_1 = 0, b_{k+2} = -\frac{b_k}{(k+3)(k+2)}, b_1 = 0\right]$

2.1.42 Problem 44

Internal problem ID [9214]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 44
Date solved : `Monday, January 27, 2025 at 05:52:09 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$(x-1)\,y''-xy'+y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.243 (sec)

Writing the ode as

$$(x-1)\,y''-xy'+y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=x-1\\ B&=-x\\ C&=1\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned}r&=\frac{s}{t}\\ &=\frac{2AB'-2BA'+B^2-4AC}{4A^2}\end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{x^2-4x+6}{4\,(x-1)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned}s&=x^2-4x+6\\ t&=4(x-1)^2\end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{x^2-4x+6}{4\,(x-1)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.78: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x-1)^2$. There is a pole at $x = 1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} + \frac{3}{4(x-1)^2} - \frac{1}{2(x-1)}$$

For the pole at $x = 1$ let b be the coefficient of $\frac{1}{(x-1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^{+} &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^{-} &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} - \frac{1}{2x} + \frac{1}{x^3} + \frac{11}{4x^4} + \frac{21}{4x^5} + \frac{15}{2x^6} + \frac{6}{x^7} - \frac{117}{16x^8} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 - 4x + 6}{4x^2 - 8x + 4} \\ &= Q + \frac{R}{4x^2 - 8x + 4} \\ &= \left(\frac{1}{4}\right) + \left(\frac{-2x + 5}{4x^2 - 8x + 4}\right) \\ &= \frac{1}{4} + \frac{-2x + 5}{4x^2 - 8x + 4} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is -2. Dividing this by leading coefficient in t which is 4 gives $-\frac{1}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{1}{2}\right) - (0) \\ &= -\frac{1}{2} \end{aligned}$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \frac{1}{2} \\
\alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &= -\frac{1}{2} \\
\alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &= \frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2 - 4x + 6}{4(x-1)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
1	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	$-\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{+} = -\frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^{+} - \left(\alpha_{c_1}^{-}\right) \\
&= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1} \right) + (+)[\sqrt{r}]_\infty \\
&= -\frac{1}{2(x-1)} + \left(\frac{1}{2}\right) \\
&= -\frac{1}{2(x-1)} + \frac{1}{2} \\
&= \frac{x-2}{2x-2}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(-\frac{1}{2\left(x-1\right)}+\frac{1}{2}\right)(0)+\left(\left(\frac{1}{2\left(x-1\right)^{2}}\right)+\left(-\frac{1}{2\left(x-1\right)}+\frac{1}{2}\right)^{2}-\left(\frac{x^{2}-4x+6}{4\left(x-1\right)^{2}}\right)\right)=0$$

$$0=0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z''=rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(-\frac{1}{2(x-1)}+\frac{1}{2}\right)dx} \\
&= \frac{\mathrm{e}^{\frac{x}{2}}}{\sqrt{x-1}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-x}{x-1}\, dx} \\
&= z_1 e^{\frac{x}{2}+\frac{\ln(x-1)}{2}} \\
&= z_1 \left(\sqrt{x-1}\, \mathrm{e}^{\frac{x}{2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-x}{x-1}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{x+\ln(x-1)}}{(y_1)^2}\, dx \\
&= y_1 \left(-\frac{x\, \mathrm{e}^{x+\ln(x-1)}\mathrm{e}^{-2x}}{x-1}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(\mathrm{e}^{x}) + c_2\left(\mathrm{e}^{x}\left(-\frac{x\, \mathrm{e}^{x+\ln(x-1)}\mathrm{e}^{-2x}}{x-1}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$(x-1)\left(\frac{d^2}{dx^2}y(x)\right)-x\left(\frac{d}{dx}y(x)\right)+y(x)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x)=-\frac{y(x)}{x-1}+\frac{\left(\frac{d}{dx}y(x)\right)x}{x-1}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x)-\frac{\left(\frac{d}{dx}y(x)\right)x}{x-1}+\frac{y(x)}{x-1}=0$

□ Check to see if $x_0=1$ is a regular singular point

  ◦ Define functions

  $\left[P_2(x)=-\frac{x}{x-1}, P_3(x)=\frac{1}{x-1}\right]$

  ◦ $(x-1)\cdot P_2(x)$ is analytic at $x=1$

  $\left((x-1)\cdot P_2(x)\right)\bigg|_{x=1}=-1$

  ◦ $(x-1)^2\cdot P_3(x)$ is analytic at $x=1$

  $\left((x-1)^2\cdot P_3(x)\right)\bigg|_{x=1}=0$

  ◦ $x=1$is a regular singular point

  Check to see if $x_0=1$ is a regular singular point

  $x_0=1$

- Multiply by denominators

  $(x-1)\left(\frac{d^2}{dx^2}y(x)\right)-x\left(\frac{d}{dx}y(x)\right)+y(x)=0$

- Change variables using $x=u+1$ so that the regular singular point is at $u=0$

  $u\left(\frac{d^2}{du^2}y(u)\right)+(-u-1)\left(\frac{d}{du}y(u)\right)+y(u)=0$

- Assume series solution for $y(u)$

  $y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$

  $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,u^{k+r-1+m}$

  ◦ Shift index using $k->k+1-m$

  $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,u^{k+r}$

  ◦ Convert $u\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion

  $u\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)(k+r-1)\,u^{k+r-1}$

  ◦ Shift index using $k->k+1$

  $u\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=-1}^{\infty}a_{k+1}(k+1+r)(k+r)\,u^{k+r}$

  Rewrite ODE with series expansions

  $a_0r(-2+r)\,u^{-1+r}+\left(\sum_{k=0}^{\infty}\left(a_{k+1}(k+1+r)(k+r-1)-a_k(k+r-1)\right)u^{k+r}\right)=0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$r(-2+r) = 0$

- Values of r that satisfy the indicial equation
  $r \in \{0, 2\}$
- Each term in the series must be 0, giving the recursion relation
  $(k+r-1)\,(a_{k+1}(k+1+r) - a_k) = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+1} = \frac{a_k}{k+1+r}$
- Recursion relation for $r = 0$
  $a_{k+1} = \frac{a_k}{k+1}$
- Solution for $r = 0$
  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+1} = \frac{a_k}{k+1}\right]$
- Revert the change of variables $u = x - 1$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k (x-1)^k, a_{k+1} = \frac{a_k}{k+1}\right]$
- Recursion relation for $r = 2$
  $a_{k+1} = \frac{a_k}{k+3}$
- Solution for $r = 2$
  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+2}, a_{k+1} = \frac{a_k}{k+3}\right]$
- Revert the change of variables $u = x - 1$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k (x-1)^{k+2}, a_{k+1} = \frac{a_k}{k+3}\right]$
- Combine solutions and rename parameters
  $\left[y(x) = \left(\sum_{k=0}^{\infty} a_k (x-1)^k\right) + \left(\sum_{k=0}^{\infty} b_k (x-1)^{k+2}\right), a_{k+1} = \frac{a_k}{k+1}, b_{k+1} = \frac{b_k}{k+3}\right]$

Solve

$$4x^2y'' - 4x(x+1)\,y' + (2x+3)\,y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.100 (sec)

Writing the ode as

$$4x^2y'' + \left(-4x^2 - 4x\right)y' + (2x+3)\,y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4x^2 \\ B &= -4x^2 - 4x \\ C &= 2x+3 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.80: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{1}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\frac{x}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2} \frac{-4x^2 - 4x}{4x^2}\, dx} \\ &= z_1 e^{\frac{x}{2} + \frac{\ln(x)}{2}} \\ &= z_1 \left(\sqrt{x}\, \mathrm{e}^{\frac{x}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \sqrt{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-4x^2-4x}{4x^2} dx}}{(y_1)^2} dx \\ &= y_1 \int \frac{e^{x+\ln(x)}}{(y_1)^2} dx \\ &= y_1 \left(\frac{e^{x+\ln(x)}}{x}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\sqrt{x}\right) + c_2 \left(\sqrt{x} \left(\frac{e^{x+\ln(x)}}{x}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$4x^2 \left(\frac{d^2}{dx^2} y(x)\right) - 4x(x+1) \left(\frac{d}{dx} y(x)\right) + (2x+3)\, y(x) = 0$

2.1.44 Problem 46

Internal problem ID [9216]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 46
Date solved : `Monday, January 27, 2025 at 05:52:10 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$(3x-1)\,y''-(3x+2)\,y'-(6x-8)\,y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.254 (sec)

Writing the ode as

$$(3x-1)\,y''+(-3x-2)\,y'+(-6x+8)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 3x-1 \\ B &= -3x-2 \\ C &= -6x+8 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{81x^2-108x+54}{4\,(3x-1)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 81x^2-108x+54 \\ t &= 4(3x-1)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{81x^2-108x+54}{4\,(3x-1)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.82: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(3x-1)^2$. There is a pole at $x = \frac{1}{3}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{9}{4} + \frac{3}{4\left(x-\frac{1}{3}\right)^2} - \frac{3}{2\left(x-\frac{1}{3}\right)}$$

For the pole at $x = \frac{1}{3}$ let b be the coefficient of $\frac{1}{\left(x-\frac{1}{3}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\
&= \sum_{i=0}^{0} a_i x^i \qquad (8)
\end{aligned}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{3}{2} - \frac{1}{2x} + \frac{1}{9x^3} + \frac{11}{108x^4} + \frac{7}{108x^5} + \frac{5}{162x^6} + \frac{2}{243x^7} - \frac{13}{3888x^8} + \dots \qquad (9)$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{3}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\
&= \frac{3}{2} \qquad (10)
\end{aligned}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{9}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{81x^2 - 108x + 54}{36x^2 - 24x + 4} \\
&= Q + \frac{R}{36x^2 - 24x + 4} \\
&= \left(\frac{9}{4}\right) + \left(\frac{-54x + 45}{36x^2 - 24x + 4}\right) \\
&= \frac{9}{4} + \frac{-54x + 45}{36x^2 - 24x + 4}
\end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is -54. Dividing this by leading coefficient in t which is 36 gives $-\frac{3}{2}$. Now b can be found.

$$\begin{aligned}
b &= \left(-\frac{3}{2}\right) - (0) \\
&= -\frac{3}{2}
\end{aligned}$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \frac{3}{2} \\
\alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-\frac{3}{2}}{\frac{3}{2}} - 0\right) &= -\frac{1}{2} \\
\alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-\frac{3}{2}}{\frac{3}{2}} - 0\right) &= \frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{81x^2 - 108x + 54}{4(3x-1)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
$\frac{1}{3}$	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{3}{2}$	$-\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = -\frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^+ - (\alpha_{c_1}^-) \\
&= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty
$$

Substituting the above values in the above results in

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + (+)[\sqrt{r}]_\infty \\
&= -\frac{1}{2\left(x-\frac{1}{3}\right)} + \left(\frac{3}{2}\right) \\
&= -\frac{1}{2\left(x-\frac{1}{3}\right)} + \frac{3}{2} \\
&= \frac{9x-6}{6x-2}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(-\frac{1}{2\left(x-\frac{1}{3}\right)}+\frac{3}{2}\right)(0)+\left(\left(\frac{1}{2\left(x-\frac{1}{3}\right)^2}\right)+\left(-\frac{1}{2\left(x-\frac{1}{3}\right)}+\frac{3}{2}\right)^2-\left(\frac{81x^2-108x+54}{4\left(3x-1\right)^2}\right)\right)=0$$

$$0=0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z''=rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx}\\
&= \mathrm{e}^{\int \left(-\frac{1}{2\left(x-\frac{1}{3}\right)}+\frac{3}{2}\right)dx}\\
&= \frac{\mathrm{e}^{\frac{3x}{2}}}{\sqrt{3x-1}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx}\\
&= z_1 e^{-\int \frac{1}{2}\frac{-3x-2}{3x-1}\, dx}\\
&= z_1 e^{\frac{x}{2}+\frac{\ln(3x-1)}{2}}\\
&= z_1\left(\sqrt{3x-1}\,\mathrm{e}^{\frac{x}{2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1=\mathrm{e}^{2x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2=y_1\int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1\int \frac{e^{\int -\frac{-3x-2}{3x-1}\, dx}}{\left(y_1\right)^2}\, dx\\
&= y_1\int \frac{e^{x+\ln(3x-1)}}{\left(y_1\right)^2}\, dx\\
&= y_1\left(-\frac{x\,\mathrm{e}^{x+\ln(3x-1)}\mathrm{e}^{-4x}}{3x-1}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1y_1+c_2y_2\\
&= c_1\left(\mathrm{e}^{2x}\right)+c_2\left(\mathrm{e}^{2x}\left(-\frac{x\,\mathrm{e}^{x+\ln(3x-1)}\mathrm{e}^{-4x}}{3x-1}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$(3x-1)\left(\frac{d^2}{dx^2}y(x)\right)-(3x+2)\left(\frac{d}{dx}y(x)\right)-(6x-8)\,y(x)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x)=\frac{2(3x-4)y(x)}{3x-1}+\frac{(3x+2)\left(\frac{d}{dx}y(x)\right)}{3x-1}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x)-\frac{(3x+2)\left(\frac{d}{dx}y(x)\right)}{3x-1}-\frac{2(3x-4)y(x)}{3x-1}=0$

□ Check to see if $x_0=\frac{1}{3}$ is a regular singular point

  ◦ Define functions

    $\left[P_2(x)=-\frac{3x+2}{3x-1}, P_3(x)=-\frac{2(3x-4)}{3x-1}\right]$

  ◦ $\left(x-\frac{1}{3}\right)\cdot P_2(x)$ is analytic at $x=\frac{1}{3}$

    $\left(\left(x-\frac{1}{3}\right)\cdot P_2(x)\right)\bigg|_{x=\frac{1}{3}}=-1$

  ◦ $\left(x-\frac{1}{3}\right)^2\cdot P_3(x)$ is analytic at $x=\frac{1}{3}$

    $\left(\left(x-\frac{1}{3}\right)^2\cdot P_3(x)\right)\bigg|_{x=\frac{1}{3}}=0$

  ◦ $x=\frac{1}{3}$is a regular singular point

  Check to see if $x_0=\frac{1}{3}$ is a regular singular point

  $x_0=\frac{1}{3}$

- Multiply by denominators

  $(3x-1)\left(\frac{d^2}{dx^2}y(x)\right)+(-2-3x)\left(\frac{d}{dx}y(x)\right)+(-6x+8)\,y(x)=0$

- Change variables using $x=u+\frac{1}{3}$ so that the regular singular point is at $u=0$

  $3u\left(\frac{d^2}{du^2}y(u)\right)+(-3-3u)\left(\frac{d}{du}y(u)\right)+(-6u+6)\,y(u)=0$

- Assume series solution for $y(u)$

  $y(u)=\sum_{k=0}^{\infty} a_k u^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $u^m\cdot y(u)$ to series expansion for $m=0..1$

    $u^m\cdot y(u)=\sum_{k=0}^{\infty} a_k u^{k+r+m}$

  ◦ Shift index using $k->k-m$

    $u^m\cdot y(u)=\sum_{k=m}^{\infty} a_{k-m} u^{k+r}$

  ◦ Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$

    $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty} a_k(k+r)\,u^{k+r-1+m}$

  ◦ Shift index using $k->k+1-m$

    $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,u^{k+r}$

  ◦ Convert $u\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion

    $u\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,u^{k+r-1}$

- Shift index using $k- >k+1$

  $u \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)(k+r)\,u^{k+r}$

  Rewrite ODE with series expansions

  $3a_0 r(-2+r)\,u^{-1+r} + (3a_1(1+r)(-1+r) - 3a_0(-2+r))\,u^r + \left(\sum_{k=1}^{\infty} (3a_{k+1}(k+1+r)(k+r-1)\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $3r(-2+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{0, 2\}$

- Each term must be 0

  $3a_1(1+r)(-1+r) - 3a_0(-2+r) = 0$

- Each term in the series must be 0, giving the recursion relation

  $3a_{k+1}(k+1+r)(k+r-1) + a_k(-3k-3r+6) - 6a_{k-1} = 0$

- Shift index using $k- >k+1$

  $3a_{k+2}(k+2+r)(k+r) + a_{k+1}(-3k+3-3r) - 6a_k = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+2} = \frac{ka_{k+1}+ra_{k+1}+2a_k-a_{k+1}}{(k+2+r)(k+r)}$

- Recursion relation for $r = 0$

  $a_{k+2} = \frac{ka_{k+1}+2a_k-a_{k+1}}{(k+2)k}$

- Series not valid for $r = 0$, division by 0 in the recursion relation at $k = 0$

  $a_{k+2} = \frac{ka_{k+1}+2a_k-a_{k+1}}{(k+2)k}$

- Recursion relation for $r = 2$

  $a_{k+2} = \frac{ka_{k+1}+2a_k+a_{k+1}}{(k+4)(k+2)}$

- Solution for $r = 2$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+2}, a_{k+2} = \frac{ka_{k+1}+2a_k+a_{k+1}}{(k+4)(k+2)}, 9a_1 = 0\right]$

- Revert the change of variables $u = x - \frac{1}{3}$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k \left(x-\frac{1}{3}\right)^{k+2}, a_{k+2} = \frac{ka_{k+1}+2a_k+a_{k+1}}{(k+4)(k+2)}, 9a_1 = 0\right]$

CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$(2+x)\,y''+xy'+3y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.319 (sec)

Writing the ode as

$$(2+x)\,y''+xy'+3y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A&=2+x\\ B&=x\\ C&=3 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r&=\frac{s}{t}\\ &=\frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{x^2-12x-20}{4\,(2+x)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s&=x^2-12x-20\\ t&=4(2+x)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{x^2-12x-20}{4\,(2+x)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.84: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(2+x)^2$. There is a pole at $x = -2$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} + \frac{2}{(2+x)^2} - \frac{4}{2+x}$$

For the pole at $x = -2$ let b be the coefficient of $\frac{1}{(2+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1 \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} - \frac{4}{x} - \frac{6}{x^2} - \frac{72}{x^3} - \frac{556}{x^4} - \frac{5440}{x^5} - \frac{55088}{x^6} - \frac{586688}{x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{2}\end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 - 12x - 20}{4x^2 + 16x + 16} \\ &= Q + \frac{R}{4x^2 + 16x + 16} \\ &= \left(\frac{1}{4}\right) + \left(\frac{-16x - 24}{4x^2 + 16x + 16}\right) \\ &= \frac{1}{4} + \frac{-16x - 24}{4x^2 + 16x + 16} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is -16. Dividing this by leading coefficient in t which is 4 gives -4. Now b can be found.

$$\begin{aligned} b &= (-4) - (0) \\ &= -4 \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-4}{\frac{1}{2}} - 0\right) &&= -4 \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-4}{\frac{1}{2}} - 0\right) &&= 4 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2 - 12x - 20}{4(2+x)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
-2	2	0	2	-1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	-4	4

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 4$ then

$$\begin{aligned}
d &= \alpha_\infty^- - (\alpha_{c_1}^+) \\
&= 4 - (2) \\
&= 2
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x - c_1} \right) + (-)[\sqrt{r}]_\infty \\
&= \frac{2}{2+x} + (-)\left(\frac{1}{2}\right) \\
&= \frac{2}{2+x} - \frac{1}{2} \\
&= -\frac{x-2}{2(2+x)}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 2$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = x^2 + a_1 x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(2) + 2\left(\frac{2}{2+x} - \frac{1}{2}\right)(2x + a_1) + \left(\left(-\frac{2}{(2+x)^2}\right) + \left(\frac{2}{2+x} - \frac{1}{2}\right)^2 - \left(\frac{x^2 - 12x - 20}{4(2+x)^2}\right)\right) = 0$$

$$\frac{(a_1 + 6)\, x + 2a_0 + 2a_1 + 4}{2+x} = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 4, a_1 = -6\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^2 - 6x + 4$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= pe^{\int \omega\, dx} \\ &= \left(x^2 - 6x + 4\right) e^{\int \left(\frac{2}{2+x} - \frac{1}{2}\right) dx} \\ &= \left(x^2 - 6x + 4\right) e^{-\frac{x}{2} + 2\ln(2+x)} \\ &= \left(x^2 - 6x + 4\right) (2+x)^2 e^{-\frac{x}{2}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{x}{2+x}\, dx} \\ &= z_1 e^{-\frac{x}{2} + \ln(2+x)} \\ &= z_1\left((2+x)\, e^{-\frac{x}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = (2+x)^3 e^{-x} \left(x^2 - 6x + 4\right)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{x}{2+x}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-x + 2\ln(2+x)}}{(y_1)^2}\, dx \\ &= y_1 \left(-\frac{e^x (x^4 - x^3 - 18x^2 - 22x + 8)}{240\, (x^2 - 6x + 4)\, (2+x)^3} - \frac{e^{-2}\, \mathrm{Ei}_1(-2-x)}{240}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left((2+x)^3 e^{-x} \left(x^2 - 6x + 4\right)\right) \\ &\quad + c_2\left((2+x)^3 e^{-x} \left(x^2 - 6x + 4\right) \left(-\frac{e^x (x^4 - x^3 - 18x^2 - 22x + 8)}{240\, (x^2 - 6x + 4)\, (2+x)^3} - \frac{e^{-2}\, \mathrm{Ei}_1(-2-x)}{240}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

- ○ $(x+2)\cdot P_2(x)$ is analytic at $x=-2$

  $\left((x+2)\cdot P_2(x)\right)\Big|_{x=-2}=-2$

- ○ $(x+2)^2\cdot P_3(x)$ is analytic at $x=-2$

  $\left((x+2)^2\cdot P_3(x)\right)\Big|_{x=-2}=0$

- ○ $x=-2$is a regular singular point

  Check to see if $x_0=-2$ is a regular singular point

  $x_0=-2$

- Multiply by denominators

  $(x+2)\left(\frac{d^2}{dx^2}y(x)\right)+x\left(\frac{d}{dx}y(x)\right)+3y(x)=0$

- Change variables using $x=u-2$ so that the regular singular point is at $u=0$

  $u\left(\frac{d^2}{du^2}y(u)\right)+(u-2)\left(\frac{d}{du}y(u)\right)+3y(u)=0$

- Assume series solution for $y(u)$

  $y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

☐ Rewrite ODE with series expansions

- ○ Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$

  $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,u^{k+r-1+m}$

- ○ Shift index using $k->k+1-m$

  $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,u^{k+r}$

- ○ Convert $u\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion

  $u\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,u^{k+r-1}$

- ○ Shift index using $k->k+1$

  $u\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=-1}^{\infty}a_{k+1}(k+1+r)\,(k+r)\,u^{k+r}$

  Rewrite ODE with series expansions

  $a_0r(-3+r)\,u^{-1+r}+\left(\sum_{k=0}^{\infty}\left(a_{k+1}(k+1+r)\,(k-2+r)+a_k(k+r+3)\right)u^{k+r}\right)=0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$r(-3+r)=0$

- Values of r that satisfy the indicial equation

  $r\in\{0,3\}$
- Each term in the series must be 0, giving the recursion relation

  $a_{k+1}(k+1+r)(k-2+r)+a_k(k+r+3)=0$
- Recursion relation that defines series solution to ODE

  $a_{k+1}=-\frac{a_k(k+r+3)}{(k+1+r)(k-2+r)}$
- Recursion relation for $r=0$

  $a_{k+1}=-\frac{a_k(k+3)}{(k+1)(k-2)}$
- Series not valid for $r=0$, division by 0 in the recursion relation at $k=2$

  $a_{k+1}=-\frac{a_k(k+3)}{(k+1)(k-2)}$
- Recursion relation for $r=3$

  $a_{k+1}=-\frac{a_k(k+6)}{(k+4)(k+1)}$
- Solution for $r=3$

  $\left[y(u)=\sum_{k=0}^{\infty}a_k u^{k+3}, a_{k+1}=-\frac{a_k(k+6)}{(k+4)(k+1)}\right]$
- Revert the change of variables $u=x+2$

  $\left[y(x)=\sum_{k=0}^{\infty}a_k(x+2)^{k+3}, a_{k+1}=-\frac{a_k(k+6)}{(k+4)(k+1)}\right]$

2.1.46 Problem 48

Internal problem ID [9218]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 48
Date solved : `Monday, January 27, 2025 at 05:52:11 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2(1-x)\,y''+x(4+x)\,y'+(2-x)\,y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.236 (sec)

Writing the ode as

$$\left(-x^3+x^2\right)y''+\left(x^2+4x\right)y'+(2-x)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=-x^3+x^2\\B&=x^2+4x\\C&=2-x\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned}r&=\frac{s}{t}\\&=\frac{2AB'-2BA'+B^2-4AC}{4A^2}\end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{-x+36}{4x\left(-1+x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned}s&=-x+36\\t&=4x(-1+x)^2\end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{-x+36}{4x\left(-1+x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.86: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 3 - 1 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x(-1+x)^2$. There is a pole at $x = 0$ of order 1. There is a pole at $x = 1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 1. For the pole at $x = 0$ of order 1 then

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= 1 \\ \alpha_c^- &= 1 \end{aligned}$$

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{9}{-1+x} + \frac{9}{x} + \frac{35}{4\,(-1+x)^2}$$

For the pole at $x = 1$ let b be the coefficient of $\frac{1}{(-1+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{35}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{5}{2} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{-x+36}{4x\left(-1+x\right)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{1}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{-x+36}{4x\left(-1+x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	1	0	0	1
1	2	0	$\frac{7}{2}$	$-\frac{5}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^-\right) \\
&= \frac{1}{2} - \left(-\frac{3}{2}\right) \\
&= 2
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2} \right) + (-)[\sqrt{r}]_\infty \\
&= \frac{1}{x} - \frac{5}{2\left(-1+x\right)} + (-)\left(0\right) \\
&= \frac{1}{x} - \frac{5}{2\left(-1+x\right)} \\
&= \frac{1}{x} - \frac{5}{-2+2x}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 2$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x^2 + a_1 x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(2) + 2\left(\frac{1}{x} - \frac{5}{2(-1+x)}\right)(2x + a_1) + \left(\left(-\frac{1}{x^2} + \frac{5}{2(-1+x)^2}\right) + \left(\frac{1}{x} - \frac{5}{2(-1+x)}\right)^2 - \left(\frac{-x+36}{4x(-1+x)^2}\right.\right.$$

$$\frac{(a_1-6)x + 4a_0 - 2a_1}{x(-1+x)}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 3, a_1 = 6\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^2 + 6x + 3$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx} \\
&= (x^2 + 6x + 3)\, e^{\int \left(\frac{1}{x} - \frac{5}{2(-1+x)}\right) dx} \\
&= (x^2 + 6x + 3)\, e^{\ln(x) - \frac{5\ln(-1+x)}{2}} \\
&= \frac{(x^2 + 6x + 3)\, x}{(-1+x)^{5/2}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{x^2+4x}{-x^3+x^2}\, dx} \\
&= z_1 e^{-2\ln(x) + \frac{5\ln(-1+x)}{2}} \\
&= z_1 \left(\frac{(-1+x)^{5/2}}{x^2}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{x^2 + 6x + 3}{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x^2+4x}{-x^3+x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-4\ln(x) + 5\ln(-1+x)}}{(y_1)^2}\, dx \\
&= y_1 \left(\ln(x) + \frac{1}{9x} - \frac{4\left(-38x - \frac{69}{2}\right)}{9(x^2 + 6x + 3)}\right)
\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{x^2+6x+3}{x}\right) + c_2 \left(\frac{x^2+6x+3}{x}\left(\ln(x) + \frac{1}{9x} - \frac{4\left(-38x - \frac{69}{2}\right)}{9\,(x^2+6x+3)}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

2.1.47 Problem 49

Internal problem ID [9219]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 49
Date solved : `Monday, January 27, 2025 at 05:52:12 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2(1+x)\,y''+x(1+2x)\,y'-(4+6x)\,y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.230 (sec)

Writing the ode as

$$x^2(1+x)\,y''+\left(2x^2+x\right)y'+(-6x-4)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2(1+x) \\ B &= 2x^2+x \\ C &= -6x-4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{24x^2+40x+15}{4\left(x^2+x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 24x^2+40x+15 \\ t &= 4\left(x^2+x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{24x^2+40x+15}{4\left(x^2+x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.87: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^2+x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{5}{2\,(1+x)} - \frac{1}{4\,(1+x)^2} + \frac{15}{4x^2} + \frac{5}{2x}$$

For the pole at $x = -1$ let b be the coefficient of $\frac{1}{(1+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{15}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{2} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{24x^2 + 40x + 15}{4(x^2 + x)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = 6$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = 3 \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -2
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{24x^2 + 40x + 15}{4(x^2 + x)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
-1	2	0	$\frac{1}{2}$	$\frac{1}{2}$
0	2	0	$\frac{5}{2}$	$-\frac{3}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	3	-2

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = 3$ then

$$\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^+ + \alpha_{c_2}^+\right) \\
&= 3 - (3) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1}\right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x-c_2}\right) + (+)[\sqrt{r}]_\infty \\
&= \frac{1}{2+2x} + \frac{5}{2x} + (0) \\
&= \frac{1}{2+2x} + \frac{5}{2x} \\
&= \frac{6x+5}{2x(1+x)}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{2+2x} + \frac{5}{2x}\right)(0) + \left(\left(-\frac{1}{2(1+x)^2} - \frac{5}{2x^2}\right) + \left(\frac{1}{2+2x} + \frac{5}{2x}\right)^2 - \left(\frac{24x^2+40x+15}{4(x^2+x)^2}\right)\right) = 0$$

$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= e^{\int \left(\frac{1}{2+2x} + \frac{5}{2x}\right) dx} \\
&= x^{5/2}\sqrt{1+x}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{2x^2+x}{x^2(1+x)} \, dx} \\
&= z_1 e^{-\frac{\ln(x(1+x))}{2}} \\
&= z_1\left(\frac{1}{\sqrt{x(1+x)}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{x^{5/2}\sqrt{1+x}}{\sqrt{x(1+x)}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{2x^2+x}{x^2(1+x)} \, dx}}{(y_1)^2} \, dx \\
&= y_1 \int \frac{e^{-\ln(x(1+x))}}{(y_1)^2} \, dx \\
&= y_1\left(-\frac{1}{4x^4} - \frac{1}{2x^2} + \ln(x) + \frac{1}{3x^3} + \frac{1}{x} - \ln(1+x)\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{x^{5/2}\sqrt{1+x}}{\sqrt{x(1+x)}}\right) + c_2\left(\frac{x^{5/2}\sqrt{1+x}}{\sqrt{x(1+x)}}\left(-\frac{1}{4x^4} - \frac{1}{2x^2} + \ln(x) + \frac{1}{3x^3} + \frac{1}{x} - \ln(1+x)\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

2.1.48 Problem 50

Internal problem ID [9220]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 50
Date solved : Monday, January 27, 2025 at 05:52:13 PM
CAS classification : [[_2nd_order, _with_linear_symmetries]]

Solve

$$x^2\left(2x^2+1\right)y''+x\left(2x^2+4\right)y'+2\left(-x^2+1\right)y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.431 (sec)

Writing the ode as

$$\left(2x^4+x^2\right)y''+\left(2x^3+4x\right)y'+\left(-2x^2+2\right)y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2x^4+x^2 \\ B &= 2x^3+4x \\ C &= -2x^2+2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{3x^2-9}{\left(2x^2+1\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 3x^2-9 \\ t &= \left(2x^2+1\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{3x^2-9}{\left(2x^2+1\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.89: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (2x^2 + 1)^2$. There is a pole at $x = \frac{i\sqrt{2}}{2}$ of order 2. There is a pole at $x = -\frac{i\sqrt{2}}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{21}{16\left(x - \frac{i\sqrt{2}}{2}\right)^2} + \frac{21}{16\left(x + \frac{i\sqrt{2}}{2}\right)^2} + \frac{15i\sqrt{2}}{16\left(x - \frac{i\sqrt{2}}{2}\right)} - \frac{15i\sqrt{2}}{16\left(x + \frac{i\sqrt{2}}{2}\right)}$$

For the pole at $x = \frac{i\sqrt{2}}{2}$ let b be the coefficient of $\frac{1}{\left(x - \frac{i\sqrt{2}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{21}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{7}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{3}{4} \end{aligned}$$

For the pole at $x = -\frac{i\sqrt{2}}{2}$ let b be the coefficient of $\frac{1}{\left(x+\frac{i\sqrt{2}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{21}{16}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{4} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{4}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = \frac{3x^2 - 9}{(2x^2+1)^2}
$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{3}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{3x^2 - 9}{(2x^2+1)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
$\frac{i\sqrt{2}}{2}$	2	0	$\frac{7}{4}$	$-\frac{3}{4}$
$-\frac{i\sqrt{2}}{2}$	2	0	$\frac{7}{4}$	$-\frac{3}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -\frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^-\right) \\
&= -\frac{1}{2} - \left(-\frac{3}{2}\right) \\
&= 1
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2}\right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{3}{4\left(x-\frac{i\sqrt{2}}{2}\right)} - \frac{3}{4\left(x+\frac{i\sqrt{2}}{2}\right)} + (-)(0) \\
&= -\frac{3}{4\left(x-\frac{i\sqrt{2}}{2}\right)} - \frac{3}{4\left(x+\frac{i\sqrt{2}}{2}\right)} \\
&= -\frac{3x}{2x^2+1}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{3}{4\left(x-\frac{i\sqrt{2}}{2}\right)} - \frac{3}{4\left(x+\frac{i\sqrt{2}}{2}\right)}\right)(1) + \left(\left(\frac{3}{4\left(x-\frac{i\sqrt{2}}{2}\right)^2} + \frac{3}{4\left(x+\frac{i\sqrt{2}}{2}\right)^2}\right) + \left(-\frac{3}{4\left(x-\frac{i\sqrt{2}}{2}\right)} -\right.\right.$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx} \\
&= (x)\, \mathrm{e}^{\int \left(-\frac{3}{4\left(x-\frac{i\sqrt{2}}{2}\right)} - \frac{3}{4\left(x+\frac{i\sqrt{2}}{2}\right)}\right) dx} \\
&= (x)\, \frac{1}{\left((i\sqrt{2}-2x)\,(2x+i\sqrt{2})\right)^{3/4}} \\
&= \frac{x}{(-4x^2-2)^{3/4}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{2x^3+4x}{2x^4+x^2}\, dx} \\
&= z_1 e^{\frac{3\ln(2x^2+1)}{4} - 2\ln(x)} \\
&= z_1 \left(\frac{(2x^2+1)^{3/4}}{x^2}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{2^{1/4}(4x^2+2)^{3/4}}{2x\,(-4x^2-2)^{3/4}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{2x^3+4x}{2x^4+x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{\frac{3\ln(2x^2+1)}{2}-4\ln(x)}}{(y_1)^2}\,dx \\
&= y_1 \left(-\frac{2i(2x^4-x^2-1)\sqrt{2x^2+1}\,\sqrt{2}\,\sqrt{\frac{(-4x^2-2)(4x^2+2)}{(2x^2+1)^2}}}{x\sqrt{-4x^2-2}\,\sqrt{4x^2+2}} \right. \\
&\quad \left. - \frac{6i\,\mathrm{arcsinh}\left(\sqrt{2}\,x\right)\sqrt{\frac{(-4x^2-2)(4x^2+2)}{(2x^2+1)^2}}\,(2x^2+1)}{\sqrt{-4x^2-2}\,\sqrt{4x^2+2}}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{2^{1/4}(4x^2+2)^{3/4}}{2x\,(-4x^2-2)^{3/4}}\right) + c_2\left(\frac{2^{1/4}(4x^2+2)^{3/4}}{2x\,(-4x^2-2)^{3/4}}\right)\left(-\frac{2i(2x^4-x^2-1)\sqrt{2x^2+1}\,\sqrt{2}\,\sqrt{\frac{(-4x^2-2)(4x^2+2)}{(2x^2+1)^2}}}{x\sqrt{-4x^2-2}\,\sqrt{4x^2+2}} - \frac{6i\,\mathrm{ar}}{}\right.
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2(2x^2+1)\left(\frac{d^2}{dx^2}y(x)\right) + x(2x^2+4)\left(\frac{d}{dx}y(x)\right) + 2(-x^2+1)\,y(x) = 0$

◦ Convert $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m = 2..4$

$x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r-2+m}$

◦ Shift index using $k- >k+2-m$

$x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$

Rewrite ODE with series expansions

$a_0(2+r)\,(1+r)\,x^r + a_1(3+r)\,(2+r)\,x^{1+r} + \left(\sum_{k=2}^{\infty} (a_k(k+r+2)\,(k+r+1) + 2a_{k-2}(k+r-1\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$(2+r)\,(1+r) = 0$

- Values of r that satisfy the indicial equation

$r \in \{-2, -1\}$

- Each term must be 0

$a_1(3+r)\,(2+r) = 0$

- Solve for the dependent coefficient(s)

$a_1 = 0$

- Each term in the series must be 0, giving the recursion relation

$a_k(k+r+2)\,(k+r+1) + 2a_{k-2}(k+r-1)\,(k-3+r) = 0$

- Shift index using $k- >k+2$

$a_{k+2}(k+4+r)\,(k+3+r) + 2a_k(k+r+1)\,(k+r-1) = 0$

- Recursion relation that defines series solution to ODE

$a_{k+2} = -\frac{2a_k(k+r+1)(k+r-1)}{(k+4+r)(k+3+r)}$

- Recursion relation for $r = -2$

$a_{k+2} = -\frac{2a_k(k-1)(k-3)}{(k+2)(k+1)}$

- Solution for $r = -2$

$\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k-2}, a_{k+2} = -\frac{2a_k(k-1)(k-3)}{(k+2)(k+1)}, a_1 = 0\right]$

- Recursion relation for $r = -1$; series terminates at $k = 2$

$a_{k+2} = -\frac{2a_k k(k-2)}{(k+3)(k+2)}$

- Solution for $r = -1$

$$\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k-1}, a_{k+2} = -\frac{2a_k k(k-2)}{(k+3)(k+2)}, a_1 = 0\right]$$

- Combine solutions and rename parameters

$$\left[y(x) = \left(\sum_{k=0}^{\infty} a_k x^{k-2}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k-1}\right), a_{k+2} = -\frac{2a_k(k-1)(k-3)}{(k+2)(k+1)}, a_1 = 0, b_{k+2} = -\frac{2b_k k(k-2)}{(k+3)(k+2)}, b_1 = 0\right]$$

2.1.49 Problem 51

Internal problem ID [9221]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 51
Date solved : `Monday, January 27, 2025 at 05:52:13 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2\left(x^2+2\right)y''+2x\left(x^2+5\right)y'+2\left(-x^2+3\right)y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.472 (sec)

Writing the ode as

$$\left(x^4+2x^2\right)y''+\left(2x^3+10x\right)y'+\left(-2x^2+6\right)y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^4+2x^2 \\ B &= 2x^3+10x \\ C &= -2x^2+6 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{2x^4-5x^2+3}{\left(x^3+2x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 2x^4-5x^2+3 \\ t &= \left(x^3+2x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{2x^4-5x^2+3}{\left(x^3+2x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.91: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 4 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (x^3 + 2x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = i\sqrt{2}$ of order 2. There is a pole at $x = -i\sqrt{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{3}{4x^2} + \frac{21}{16\left(x - i\sqrt{2}\right)^2} + \frac{21}{16\left(x + i\sqrt{2}\right)^2} + \frac{11i\sqrt{2}}{32\left(x - i\sqrt{2}\right)} - \frac{11i\sqrt{2}}{32\left(x + i\sqrt{2}\right)}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

For the pole at $x = i\sqrt{2}$ let b be the coefficient of $\frac{1}{\left(x-i\sqrt{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{21}{16}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{4} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{4}
\end{aligned}$$

For the pole at $x = -i\sqrt{2}$ let b be the coefficient of $\frac{1}{\left(x+i\sqrt{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{21}{16}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{4} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{4}
\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{2x^4 - 5x^2 + 3}{\left(x^3 + 2x\right)^2}$$

Since the $\gcd(s, t) = 1$. This gives $b = 2$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -1
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{2x^4 - 5x^2 + 3}{\left(x^3 + 2x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{3}{2}$	$-\frac{1}{2}$
$i\sqrt{2}$	2	0	$\frac{7}{4}$	$-\frac{3}{4}$
$-i\sqrt{2}$	2	0	$\frac{7}{4}$	$-\frac{3}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	2	-1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = 2$ then

$$\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^+ + \alpha_{c_2}^- + \alpha_{c_3}^-\right) \\
&= 2 - (0) \\
&= 2
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2} \right) + \left((-)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^-}{x-c_3} \right) + (+)[\sqrt{r}]_\infty \\
&= \frac{3}{2x} - \frac{3}{4\left(x-i\sqrt{2}\right)} - \frac{3}{4\left(x+i\sqrt{2}\right)} + (0) \\
&= \frac{3}{2x} - \frac{3}{4\left(x-i\sqrt{2}\right)} - \frac{3}{4\left(x+i\sqrt{2}\right)} \\
&= \frac{3}{x^3+2x}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 2$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x^2 + a_1 x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(2) + 2\left(\frac{3}{2x} - \frac{3}{4\left(x-i\sqrt{2}\right)} - \frac{3}{4\left(x+i\sqrt{2}\right)} \right)(2x+a_1) + \left(\left(-\frac{3}{2x^2} + \frac{3}{4\left(x-i\sqrt{2}\right)^2} + \frac{3}{4\left(x+i\sqrt{2}\right)^2} \right) + \left(\frac{3}{2 \right.$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 8, a_1 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^2 + 8$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx} \\
&= \left(x^2+8\right) e^{\int \left(\frac{3}{2x} - \frac{3}{4\left(x-i\sqrt{2}\right)} - \frac{3}{4\left(x+i\sqrt{2}\right)} \right) dx} \\
&= \left(x^2+8\right) e^{-\frac{3\ln\left(x^2+2\right)}{4} + \frac{3\ln(x)}{2}} \\
&= \frac{\left(x^2+8\right) x^{3/2}}{\left(x^2+2\right)^{3/4}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{2x^3+10x}{x^4+2x^2}\, dx} \\
&= z_1 e^{\frac{3\ln\left(x^2+2\right)}{4} - \frac{5\ln(x)}{2}} \\
&= z_1 \left(\frac{\left(x^2+2\right)^{3/4}}{x^{5/2}} \right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{x^2+8}{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{2x^3+10x}{x^4+2x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{\frac{3\ln(x^2+2)}{2}-5\ln(x)}}{(y_1)^2}\, dx \\
&= y_1 \left(-\frac{(x^2+2)^{5/2}}{256x^2} + \frac{(x^2+2)^{3/2}}{384} + \frac{\sqrt{x^2+2}}{96} - \frac{\sqrt{2}\,\operatorname{arctanh}\left(\frac{\sqrt{2}}{\sqrt{x^2+2}}\right)}{64} + \frac{3\sqrt{x^2+2}}{64\,(x^2+8)} \right. \\
&\qquad \left. + \frac{x^2\sqrt{x^2+2}}{768}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{x^2+8}{x}\right) + c_2\left(\frac{x^2+8}{x}\left(-\frac{(x^2+2)^{5/2}}{256x^2} + \frac{(x^2+2)^{3/2}}{384} + \frac{\sqrt{x^2+2}}{96}\right.\right. \\
&\qquad \left.\left. - \frac{\sqrt{2}\,\operatorname{arctanh}\left(\frac{\sqrt{2}}{\sqrt{x^2+2}}\right)}{64} + \frac{3\sqrt{x^2+2}}{64\,(x^2+8)} + \frac{x^2\sqrt{x^2+2}}{768}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2(x^2+2)\left(\frac{d^2}{dx^2}y(x)\right) + 2x(x^2+5)\left(\frac{d}{dx}y(x)\right) + 2(-x^2+3)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = \frac{2(x^2-3)y(x)}{(x^2+2)x^2} - \frac{2(x^2+5)\left(\frac{d}{dx}y(x)\right)}{x(x^2+2)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x) + \frac{2(x^2+5)\left(\frac{d}{dx}y(x)\right)}{x(x^2+2)} - \frac{2(x^2-3)y(x)}{(x^2+2)x^2} = 0$

☐ Check to see if x_0 is a regular singular point

  ◦ Define functions

  $\left[P_2(x) = \frac{2(x^2+5)}{x(x^2+2)}, P_3(x) = -\frac{2(x^2-3)}{(x^2+2)x^2}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

$(x \cdot P_2(x)) \bigg|_{x=0} = 5$

- $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $(x^2 \cdot P_3(x)) \bigg|_{x=0} = 3$

- $x = 0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $x^2(x^2+2)\left(\frac{d^2}{dx^2}y(x)\right) + 2x(x^2+5)\left(\frac{d}{dx}y(x)\right) + (-2x^2+6)\,y(x) = 0$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

- Convert $x^m \cdot y(x)$ to series expansion for $m = 0..2$

  $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- Shift index using $k- >k-m$

  $x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m = 1..3$

  $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$

- Shift index using $k- >k+1-m$

  $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$

- Convert $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m = 2..4$

  $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r-2+m}$

- Shift index using $k- >k+2-m$

  $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$

  Rewrite ODE with series expansions

  $2a_0(3+r)\,(1+r)\,x^r + 2a_1(4+r)\,(2+r)\,x^{1+r} + \left(\sum_{k=2}^{\infty} (2a_k(k+r+3)\,(k+r+1) + a_{k-2}(k+r)\,(k\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $2(3+r)\,(1+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{-3, -1\}$

- Each term must be 0

  $2a_1(4+r)\,(2+r) = 0$

- Solve for the dependent coefficient(s)

  $a_1 = 0$

- Each term in the series must be 0, giving the recursion relation

  $2a_k(k+r+3)\,(k+r+1) + a_{k-2}(k+r)\,(k-3+r) = 0$

- Shift index using $k- >k+2$

  $2a_{k+2}(k+5+r)\,(k+r+3) + a_k(k+r+2)\,(k+r-1) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{a_k(k+r+2)(k+r-1)}{2(k+5+r)(k+r+3)}$

- Recursion relation for $r=-3$; series terminates at $k=4$

  $a_{k+2}=-\frac{a_k(k-1)(k-4)}{2(k+2)k}$

- Solution for $r=-3$

  $\left[y(x)=\sum_{k=0}^{\infty} a_k x^{k-3}, a_{k+2}=-\frac{a_k(k-1)(k-4)}{2(k+2)k}, a_1=0\right]$

- Recursion relation for $r=-1$; series terminates at $k=2$

  $a_{k+2}=-\frac{a_k(k+1)(k-2)}{2(k+4)(k+2)}$

- Solution for $r=-1$

  $\left[y(x)=\sum_{k=0}^{\infty} a_k x^{k-1}, a_{k+2}=-\frac{a_k(k+1)(k-2)}{2(k+4)(k+2)}, a_1=0\right]$

- Combine solutions and rename parameters

  $\left[y(x)=\left(\sum_{k=0}^{\infty} a_k x^{k-3}\right)+\left(\sum_{k=0}^{\infty} b_k x^{k-1}\right), a_{k+2}=-\frac{a_k(k-1)(-4+k)}{2(k+2)k}, a_1=0, b_{k+2}=-\frac{b_k(k+1)(k-2)}{2(4+k)(k+2)}, b_1=\right.$

CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$\left(x^2+1\right) y''+6xy'+6y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.296 (sec)

Writing the ode as

$$\left(x^2+1\right) y''+6xy'+6y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2+1 \\ B &= 6x \\ C &= 6 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r=\frac{-3}{\left(x^2+1\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -3 \\ t &= \left(x^2+1\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(-\frac{3}{\left(x^2+1\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.93: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 0 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (x^2 + 1)^2$. There is a pole at $x = i$ of order 2. There is a pole at $x = -i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{3}{4 (x - i)^2} + \frac{3}{4 (x + i)^2} + \frac{3i}{4 (x - i)} - \frac{3i}{4 (x + i)}$$

For the pole at $x = i$ let b be the coefficient of $\frac{1}{(x-i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{1}{2} \end{aligned}$$

For the pole at $x = -i$ let b be the coefficient of $\frac{1}{(x+i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $4 > 2$ then

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= 0 \\
\alpha_\infty^{-} &= 1
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = -\frac{3}{\left(x^2+1\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
i	2	0	$\frac{3}{2}$	$-\frac{1}{2}$
$-i$	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = 1$ then

$$\begin{aligned}
d &= \alpha_\infty^{-} - \left(\alpha_{c_1}^{-} + \alpha_{c_2}^{+}\right) \\
&= 1 - (1) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x-c_1} \right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{+}}{x-c_2} \right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{1}{2\left(x-i\right)} + \frac{3}{2\left(x+i\right)} + (-)\left(0\right) \\
&= -\frac{1}{2\left(x-i\right)} + \frac{3}{2\left(x+i\right)} \\
&= \frac{x-2i}{x^2+1}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(-\frac{1}{2\left(x-i\right)}+\frac{3}{2\left(x+i\right)}\right)(0)+\left(\left(\frac{1}{2\left(x-i\right)^{2}}-\frac{3}{2\left(x+i\right)^{2}}\right)+\left(-\frac{1}{2\left(x-i\right)}+\frac{3}{2\left(x+i\right)}\right)^{2}-\left(-\frac{\quad}{(x^2}\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z''=rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= \mathrm{e}^{\int \left(-\frac{1}{2(x-i)}+\frac{3}{2(x+i)}\right)dx} \\ &= \frac{\left(x^{2}+1\right)^{3/2}}{\left(ix+1\right)^{2}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{6x}{x^{2}+1}\, dx} \\ &= z_1 e^{-\frac{3\ln\left(x^{2}+1\right)}{2}} \\ &= z_1\left(\frac{1}{\left(x^{2}+1\right)^{3/2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{1}{\left(ix+1\right)^{2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^{2}}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{6x}{x^{2}+1}\, dx}}{\left(y_1\right)^{2}}\, dx \\ &= y_1 \int \frac{e^{-3\ln\left(x^{2}+1\right)}}{\left(y_1\right)^{2}}\, dx \\ &= y_1\left(-\frac{x}{\left(x+i\right)^{2}}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\frac{1}{\left(ix+1\right)^{2}}\right)+c_2\left(\frac{1}{\left(ix+1\right)^{2}}\left(-\frac{x}{\left(x+i\right)^{2}}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Solve

$$\left(x^2+1\right)y''+2xy'-2y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.268 (sec)

Writing the ode as

$$\left(x^2+1\right)y''+2xy'-2y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A&=x^2+1\\ B&=2x\\ C&=-2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r&=\frac{s}{t} \\ &=\frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{2x^2+3}{\left(x^2+1\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s&=2x^2+3\\ t&=\left(x^2+1\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{2x^2+3}{\left(x^2+1\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.94: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (x^2+1)^2$. There is a pole at $x = i$ of order 2. There is a pole at $x = -i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4(x-i)^2} - \frac{1}{4(x+i)^2} - \frac{5i}{4(x-i)} + \frac{5i}{4(x+i)}$$

For the pole at $x = i$ let b be the coefficient of $\frac{1}{(x-i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

For the pole at $x = -i$ let b be the coefficient of $\frac{1}{(x+i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{2x^2+3}{(x^2+1)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = 2$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -1
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{2x^2+3}{(x^2+1)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
i	2	0	$\frac{1}{2}$	$\frac{1}{2}$
$-i$	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	2	-1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = 2$ then

$$\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^- + \alpha_{c_2}^-\right) \\
&= 2 - (1) \\
&= 1
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2} \right) + (+)[\sqrt{r}]_\infty \\
&= \frac{1}{2x-2i} + \frac{1}{2x+2i} + (0) \\
&= \frac{1}{2x-2i} + \frac{1}{2x+2i} \\
&= \frac{x}{x^2+1}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{2x-2i} + \frac{1}{2x+2i}\right)(1) + \left(\left(-\frac{1}{2(x-i)^2} - \frac{1}{2(x+i)^2}\right) + \left(\frac{1}{2x-2i} + \frac{1}{2x+2i}\right)^2 - \left(\frac{2x^2+3}{(x^2+1)^2}\right.\right.$$
$$-\frac{2(x^2+1)\,a_0}{(-x+i)^2\,(x+i)^2}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega\, dx} \\ &= (x)\, e^{\int \left(\frac{1}{2x-2i} + \frac{1}{2x+2i}\right) dx} \\ &= (x)\, \sqrt{(-x+i)\,(x+i)} \\ &= x\sqrt{-x^2-1} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{2x}{x^2+1}\, dx} \\ &= z_1 e^{-\frac{\ln(x^2+1)}{2}} \\ &= z_1\left(\frac{1}{\sqrt{x^2+1}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = ix$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{2x}{x^2+1}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-\ln(x^2+1)}}{(y_1)^2}\, dx \\ &= y_1\left(\arctan(x) + \frac{1}{x}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(ix) + c_2\left(ix\left(\arctan(x) + \frac{1}{x}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

2.1.52 Problem 54

Internal problem ID [9224]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 54
Date solved : `Monday, January 27, 2025 at 05:52:16 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$\left(x^2+1\right) y''-8 x y'+20 y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.265 (sec)

Writing the ode as

$$\left(x^2+1\right) y''-8 x y'+20 y=0 \tag{1}$$

$$A y''+B y'+C y=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2+1 \\ B &= -8x \\ C &= 20 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=y e^{\int \frac{B}{2 A} d x}$$

Then (2) becomes

$$z''(x)=r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2 A B'-2 B A'+B^2-4 A C}{4 A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r=\frac{-24}{\left(x^2+1\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -24 \\ t &= \left(x^2+1\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(-\frac{24}{\left(x^2+1\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.95: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 0 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (x^2+1)^2$. There is a pole at $x = i$ of order 2. There is a pole at $x = -i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{6}{(x-i)^2} + \frac{6}{(x+i)^2} + \frac{6i}{x-i} - \frac{6i}{x+i}$$

For the pole at $x = i$ let b be the coefficient of $\frac{1}{(x-i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 6$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 3 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -2 \end{aligned}$$

For the pole at $x = -i$ let b be the coefficient of $\frac{1}{(x+i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 6$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 3 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -2 \end{aligned}$$

Since the order of r at ∞ is $4 > 2$ then

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= 0 \\
\alpha_\infty^{-} &= 1
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = -\frac{24}{(x^2+1)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
i	2	0	3	-2
$-i$	2	0	3	-2

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$ then

$$
\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^+\right) \\
&= 1 - (1) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x-c_2} \right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{2}{x-i} + \frac{3}{x+i} + (-)(0) \\
&= -\frac{2}{x-i} + \frac{3}{x+i} \\
&= \frac{x-5i}{x^2+1}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(0) + 2\left(-\frac{2}{x-i} + \frac{3}{x+i}\right)(0) + \left(\left(\frac{2}{(x-i)^2} - \frac{3}{(x+i)^2} \right) + \left(-\frac{2}{x-i} + \frac{3}{x+i} \right)^2 - \left(-\frac{24}{(x^2+1)^2} \right) \right) = 0
$$

$$
0 = 0
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(-\frac{2}{x-i}+\frac{3}{x+i}\right) dx} \\
&= \frac{(x^2+1)^3}{(ix+1)^5}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-8x}{x^2+1} \, dx} \\
&= z_1 e^{2\ln(x^2+1)} \\
&= z_1 \left((x^2+1)^2\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{(x^2+1)^5}{(ix+1)^5}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-8x}{x^2+1} \, dx}}{(y_1)^2} \, dx \\
&= y_1 \int \frac{e^{4\ln(x^2+1)}}{(y_1)^2} \, dx \\
&= y_1 \left(\frac{x^4 - 2x^2 + \frac{1}{5}}{(x+i)^5}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{(x^2+1)^5}{(ix+1)^5}\right) + c_2 \left(\frac{(x^2+1)^5}{(ix+1)^5} \left(\frac{x^4 - 2x^2 + \frac{1}{5}}{(x+i)^5}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

2.1.53 Problem 55

Internal problem ID [9225]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 55
Date solved : `Monday, January 27, 2025 at 05:52:16 PM`
CAS classification : `[_Gegenbauer]`

Solve

$$\left(-x^2+1\right) y''-8 x y'-12 y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.178 (sec)

Writing the ode as

$$\left(-x^2+1\right) y''-8 x y'-12 y=0 \tag{1}$$
$$A y''+B y'+C y=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= -x^2+1 \\ B &= -8x \\ C &= -12 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=y e^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x)=r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r=\frac{8}{\left(x^2-1\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 8 \\ t &= \left(x^2-1\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{8}{\left(x^2-1\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.96: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 0 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (x^2 - 1)^2$. There is a pole at $x = 1$ of order 2. There is a pole at $x = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{2}{x+1} + \frac{2}{(x+1)^2} - \frac{2}{x-1} + \frac{2}{(x-1)^2}$$

For the pole at $x = 1$ let b be the coefficient of $\frac{1}{(x-1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1 \end{aligned}$$

For the pole at $x = -1$ let b be the coefficient of $\frac{1}{(x+1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1 \end{aligned}$$

Since the order of r at ∞ is $4 > 2$ then

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= 0 \\
\alpha_\infty^{-} &= 1
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{8}{(x^2-1)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
1	2	0	2	-1
-1	2	0	2	-1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = 1$ then

$$
\begin{aligned}
d &= \alpha_\infty^{-} - \left(\alpha_{c_1}^{-} + \alpha_{c_2}^{+}\right) \\
&= 1 - (1) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x-c_1} \right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{+}}{x-c_2} \right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{1}{x-1} + \frac{2}{x+1} + (-)(0) \\
&= -\frac{1}{x-1} + \frac{2}{x+1} \\
&= \frac{x-3}{x^2-1}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
\begin{aligned}
(0) + 2\left(-\frac{1}{x-1} + \frac{2}{x+1}\right)(0) + \left(\left(\frac{1}{(x-1)^2} - \frac{2}{(x+1)^2}\right) + \left(-\frac{1}{x-1} + \frac{2}{x+1}\right)^2 - \left(\frac{8}{(x^2-1)^2}\right)\right) &= 0 \\
0 &= 0
\end{aligned}
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= \mathrm{e}^{\int \left(-\frac{1}{x-1}+\frac{2}{x+1}\right)dx} \\ &= \frac{(x+1)^2}{x-1} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-8x}{-x^2+1}\, dx} \\ &= z_1 e^{-2\ln(x-1)-2\ln(x+1)} \\ &= z_1 \left(\frac{1}{(x-1)^2 (x+1)^2}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{1}{(x-1)^3}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-8x}{-x^2+1}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-4\ln(x-1)-4\ln(x+1)}}{(y_1)^2}\, dx \\ &= y_1 \left(-\frac{(x+1)(3x^2+1)(x-1)^4 \,\mathrm{e}^{-4\ln(x-1)-4\ln(x+1)}}{3}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\frac{1}{(x-1)^3}\right) + c_2\left(\frac{1}{(x-1)^3}\left(-\frac{(x+1)(3x^2+1)(x-1)^4 \,\mathrm{e}^{-4\ln(x-1)-4\ln(x+1)}}{3}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$(-x^2+1)\left(\frac{d^2}{dx^2}y(x)\right)-8x\left(\frac{d}{dx}y(x)\right)-12y(x)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x)=-\frac{12y(x)}{x^2-1}-\frac{8\left(\frac{d}{dx}y(x)\right)x}{x^2-1}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x)+\frac{8\left(\frac{d}{dx}y(x)\right)x}{x^2-1}+\frac{12y(x)}{x^2-1}=0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

  $\left[P_2(x)=\frac{8x}{x^2-1}, P_3(x)=\frac{12}{x^2-1}\right]$

  ◦ $(x+1)\cdot P_2(x)$ is analytic at $x=-1$

  $\left((x+1)\cdot P_2(x)\right)\Big|_{x=-1}=4$

  ◦ $(x+1)^2\cdot P_3(x)$ is analytic at $x=-1$

  $\left((x+1)^2\cdot P_3(x)\right)\Big|_{x=-1}=0$

  ◦ $x=-1$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=-1$

- Multiply by denominators

  $(x^2-1)\left(\frac{d^2}{dx^2}y(x)\right)+8x\left(\frac{d}{dx}y(x)\right)+12y(x)=0$

- Change variables using $x=u-1$ so that the regular singular point is at $u=0$

  $(u^2-2u)\left(\frac{d^2}{du^2}y(u)\right)+(8u-8)\left(\frac{d}{du}y(u)\right)+12y(u)=0$

- Assume series solution for $y(u)$

  $y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$

  $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,u^{k+r-1+m}$

  ◦ Shift index using $k->k+1-m$

  $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,u^{k+r}$

  ◦ Convert $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m=1..2$

  $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)(k+r-1)\,u^{k+r-2+m}$

  ◦ Shift index using $k->k+2-m$

  $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=-2+m}^{\infty}a_{k+2-m}(k+2-m+r)(k+1-m+r)\,u^{k+r}$

  Rewrite ODE with series expansions

  $-2a_0r(3+r)\,u^{-1+r}+\left(\sum_{k=0}^{\infty}\left(-2a_{k+1}(k+1+r)(k+r+4)+a_k(k+r+4)(k+r+3)\right)u^{k+r}\right)=0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$-2r(3+r)=0$

- Values of r that satisfy the indicial equation
  $r\in\{-3,0\}$
- Each term in the series must be 0, giving the recursion relation
  $(k+r+4)\left(\left(-2k-2r-2\right)a_{k+1}+a_k(k+r+3)\right)=0$
- Recursion relation that defines series solution to ODE
  $a_{k+1}=\frac{a_k(k+r+3)}{2(k+1+r)}$
- Recursion relation for $r=-3$
  $a_{k+1}=\frac{a_k k}{2(k-2)}$
- Series not valid for $r=-3$, division by 0 in the recursion relation at $k=2$
  $a_{k+1}=\frac{a_k k}{2(k-2)}$
- Recursion relation for $r=0$
  $a_{k+1}=\frac{a_k(k+3)}{2(k+1)}$
- Solution for $r=0$
  $\left[y(u)=\sum_{k=0}^{\infty}a_k u^k, a_{k+1}=\frac{a_k(k+3)}{2(k+1)}\right]$
- Revert the change of variables $u=x+1$
  $\left[y(x)=\sum_{k=0}^{\infty}a_k(x+1)^k, a_{k+1}=\frac{a_k(k+3)}{2(k+1)}\right]$

2.1.54 Problem 56

Internal problem ID [9226]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 56
Date solved : `Monday, January 27, 2025 at 05:52:17 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$(2x^2+1)\,y''+7xy'+2y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.337 (sec)

Writing the ode as

$$(2x^2+1)\,y''+7xy'+2y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=2x^2+1\\B&=7x\\C&=2\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned}r&=\frac{s}{t}\\&=\frac{2AB'-2BA'+B^2-4AC}{4A^2}\end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{5x^2+6}{4\,(2x^2+1)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned}s&=5x^2+6\\t&=4(2x^2+1)^2\end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{5x^2+6}{4\,(2x^2+1)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.98: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(2x^2+1)^2$. There is a pole at $x = \frac{i\sqrt{2}}{2}$ of order 2. There is a pole at $x = -\frac{i\sqrt{2}}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{7}{64\left(x - \frac{i\sqrt{2}}{2}\right)^2} - \frac{7}{64\left(x + \frac{i\sqrt{2}}{2}\right)^2} - \frac{17i\sqrt{2}}{64\left(x - \frac{i\sqrt{2}}{2}\right)} + \frac{17i\sqrt{2}}{64\left(x + \frac{i\sqrt{2}}{2}\right)}$$

For the pole at $x = \frac{i\sqrt{2}}{2}$ let b be the coefficient of $\frac{1}{\left(x-\frac{i\sqrt{2}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{7}{64}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{8} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{8} \end{aligned}$$

For the pole at $x = -\frac{i\sqrt{2}}{2}$ let b be the coefficient of $\frac{1}{\left(x+\frac{i\sqrt{2}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{7}{64}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^{+} &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{8} \\
\alpha_c^{-} &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{8}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = \frac{5x^2+6}{4\left(2x^2+1\right)^2}
$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{5}{16}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{4} \\
\alpha_\infty^{-} &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{4}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{5x^2+6}{4\left(2x^2+1\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
$\frac{i\sqrt{2}}{2}$	2	0	$\frac{7}{8}$	$\frac{1}{8}$
$-\frac{i\sqrt{2}}{2}$	2	0	$\frac{7}{8}$	$\frac{1}{8}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{5}{4}$	$-\frac{1}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{+} = \frac{5}{4}$ then

$$
\begin{aligned}
d &= \alpha_\infty^{+} - \left(\alpha_{c_1}^{-} + \alpha_{c_2}^{-}\right) \\
&= \frac{5}{4} - \left(\frac{1}{4}\right) \\
&= 1
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

Substituting the above values in the above results in

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2}\right) + (+)[\sqrt{r}]_\infty \\
&= \frac{1}{8x-4i\sqrt{2}} + \frac{1}{8x+4i\sqrt{2}} + (0) \\
&= \frac{1}{8x-4i\sqrt{2}} + \frac{1}{8x+4i\sqrt{2}} \\
&= \frac{x}{4x^2+2}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = x + a_0 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(0) + 2\left(\frac{1}{8x-4i\sqrt{2}} + \frac{1}{8x+4i\sqrt{2}}\right)(1) + \left(\left(-\frac{1}{8\left(x-\frac{i\sqrt{2}}{2}\right)^2} - \frac{1}{8\left(x+\frac{i\sqrt{2}}{2}\right)^2}\right) + \left(\frac{1}{8x-4i\sqrt{2}} + \frac{1}{8x+4i\sqrt{}}\right.\right.
$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$
\{a_0 = 0\}
$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$
p(x) = x
$$

Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= (x)\, e^{\int \left(\frac{1}{8x-4i\sqrt{2}} + \frac{1}{8x+4i\sqrt{2}}\right) dx} \\
&= (x)\left(\left(i\sqrt{2}-2x\right)\left(2x+i\sqrt{2}\right)\right)^{1/8} \\
&= x\left(-4x^2-2\right)^{1/8}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{7x}{2x^2+1}\, dx} \\
&= z_1 e^{-\frac{7\ln\left(2x^2+1\right)}{8}} \\
&= z_1 \left(\frac{1}{\left(2x^2+1\right)^{7/8}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{2^{7/8} x \left(-4x^2-2\right)^{1/8}}{\left(4x^2+2\right)^{7/8}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{7x}{2x^2+1}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-\frac{7\ln(2x^2+1)}{4}}}{(y_1)^2}\, dx \\ &= y_1 \left(\int \frac{2^{1/4}(4x^2+2)^{7/4}}{4\,(2x^2+1)^{7/4}\, x^2\, (-4x^2-2)^{1/4}} dx \right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\frac{2^{7/8} x (-4x^2-2)^{1/8}}{(4x^2+2)^{7/8}} \right) + c_2 \left(\frac{2^{7/8} x (-4x^2-2)^{1/8}}{(4x^2+2)^{7/8}} \left(\int \frac{2^{1/4}(4x^2+2)^{7/4}}{4\,(2x^2+1)^{7/4}\, x^2\, (-4x^2-2)^{1/4}} dx \right) \right) \end{aligned}$$

Will add steps showing solving for IC soon.

2.1.55 Problem 57

Internal problem ID [9227]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 57
Date solved : `Monday, January 27, 2025 at 05:52:18 PM`
CAS classification : `[_Gegenbauer]`

Solve

$$\left(-x^2+1\right) y''-5 x y'-4 y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.241 (sec)

Writing the ode as

$$\left(-x^2+1\right) y''-5 x y'-4 y=0 \tag{1}$$
$$A y''+B y'+C y=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= -x^2+1 \\ B &= -5x \\ C &= -4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x)=r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r=\frac{-x^2+6}{4\left(x^2-1\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -x^2+6 \\ t &= 4\left(x^2-1\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{-x^2+6}{4\left(x^2-1\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.99: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^2 - 1)^2$. There is a pole at $x = 1$ of order 2. There is a pole at $x = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{7}{16\,(x-1)} + \frac{5}{16\,(x-1)^2} + \frac{5}{16\,(x+1)^2} + \frac{7}{16\,(x+1)}$$

For the pole at $x = 1$ let b be the coefficient of $\frac{1}{(x-1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{5}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{4} \end{aligned}$$

For the pole at $x = -1$ let b be the coefficient of $\frac{1}{(x+1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{5}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{4} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{-x^2 + 6}{4(x^2 - 1)^2}$$

Since the $\gcd(s, t) = 1$. This gives $b = -\frac{1}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{-x^2 + 6}{4(x^2 - 1)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
1	2	0	$\frac{5}{4}$	$-\frac{1}{4}$
-1	2	0	$\frac{5}{4}$	$-\frac{1}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^- - (\alpha_{c_1}^- + \alpha_{c_2}^-) \\
&= \frac{1}{2} - \left(-\frac{1}{2}\right) \\
&= 1
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x - c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x - c_2} \right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{1}{4(x - 1)} - \frac{1}{4(x + 1)} + (-)(0) \\
&= -\frac{1}{4(x - 1)} - \frac{1}{4(x + 1)} \\
&= -\frac{x}{2x^2 - 2}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{4(x-1)} - \frac{1}{4(x+1)}\right)(1) + \left(\left(\frac{1}{4(x-1)^2} + \frac{1}{4(x+1)^2}\right) + \left(-\frac{1}{4(x-1)} - \frac{1}{4(x+1)}\right)^2 - \left(\frac{-3}{4(x\right.\right.$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega\, dx} \\ &= (x)\, e^{\int \left(-\frac{1}{4(x-1)} - \frac{1}{4(x+1)}\right) dx} \\ &= (x) \frac{1}{((x-1)(x+1))^{1/4}} \\ &= \frac{x}{(x^2-1)^{1/4}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2} \frac{-5x}{-x^2+1}\, dx} \\ &= z_1 e^{-\frac{5\ln(x-1)}{4} - \frac{5\ln(x+1)}{4}} \\ &= z_1 \left(\frac{1}{(x-1)^{5/4}(x+1)^{5/4}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{x}{(x-1)^{5/4}(x+1)^{5/4}(x^2-1)^{1/4}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-5x}{-x^2+1}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-\frac{5\ln(x-1)}{2} - \frac{5\ln(x+1)}{2}}}{(y_1)^2}\, dx \\ &= y_1 \left(\frac{(x^2-1)^{3/2}}{x} - x\sqrt{x^2-1} + \ln\left(x + \sqrt{x^2-1}\right)\right) \end{aligned}$$

Therefore the solution is

$$y = c_1 y_1 + c_2 y_2$$
$$= c_1 \left(\frac{x}{(x-1)^{5/4}(x+1)^{5/4}(x^2-1)^{1/4}} \right) + c_2 \left(\frac{x}{(x-1)^{5/4}(x+1)^{5/4}(x^2-1)^{1/4}} \left(\frac{(x^2-1)^{3/2}}{x} - x\sqrt{x^2-1} + \right. \right.$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$(-x^2+1)\left(\frac{d^2}{dx^2}y(x)\right) - 5x\left(\frac{d}{dx}y(x)\right) - 4y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{4y(x)}{x^2-1} - \frac{5\left(\frac{d}{dx}y(x)\right)x}{x^2-1}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x) + \frac{5\left(\frac{d}{dx}y(x)\right)x}{x^2-1} + \frac{4y(x)}{x^2-1} = 0$

- □ Check to see if x_0 is a regular singular point
  - ◦ Define functions

    $\left[P_2(x) = \frac{5x}{x^2-1}, P_3(x) = \frac{4}{x^2-1}\right]$
  - ◦ $(x+1) \cdot P_2(x)$ is analytic at $x = -1$

    $\left((x+1) \cdot P_2(x)\right)\Big|_{x=-1} = \frac{5}{2}$
  - ◦ $(x+1)^2 \cdot P_3(x)$ is analytic at $x = -1$

    $\left((x+1)^2 \cdot P_3(x)\right)\Big|_{x=-1} = 0$
  - ◦ $x = -1$is a regular singular point

    Check to see if x_0 is a regular singular point

    $x_0 = -1$

- Multiply by denominators

  $(x^2-1)\left(\frac{d^2}{dx^2}y(x)\right) + 5x\left(\frac{d}{dx}y(x)\right) + 4y(x) = 0$

- Change variables using $x = u-1$ so that the regular singular point is at $u = 0$

  $(u^2-2u)\left(\frac{d^2}{du^2}y(u)\right) + (5u-5)\left(\frac{d}{du}y(u)\right) + 4y(u) = 0$

- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

- □ Rewrite ODE with series expansions
  - ◦ Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..1$

    $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, u^{k+r-1+m}$
  - ◦ Shift index using $k->k+1-m$

    $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$
  - ◦ Convert $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m = 1..2$

$$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\,u^{k+r-2+m}$$

- Shift index using $k->k+2-m$

$$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\,u^{k+r}$$

Rewrite ODE with series expansions

$$-a_0 r(3+2r)\,u^{-1+r} + \left(\sum_{k=0}^{\infty}\left(-a_{k+1}(k+1+r)(2k+5+2r) + a_k(k+r+2)^2\right)u^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
$$-r(3+2r) = 0$$
- Values of r that satisfy the indicial equation
$$r \in \left\{0, -\frac{3}{2}\right\}$$
- Each term in the series must be 0, giving the recursion relation
$$a_k(k+r+2)^2 - 2(k+1+r)\,a_{k+1}\left(k+\frac{5}{2}+r\right) = 0$$
- Recursion relation that defines series solution to ODE
$$a_{k+1} = \frac{a_k(k+r+2)^2}{(k+1+r)(2k+5+2r)}$$
- Recursion relation for $r=0$
$$a_{k+1} = \frac{a_k(k+2)^2}{(k+1)(2k+5)}$$
- Solution for $r=0$

2.1.56 Problem 58

Internal problem ID [9228]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 58
Date solved : Monday, January 27, 2025 at 05:52:18 PM
CAS classification : [[_2nd_order, _with_linear_symmetries]]

Solve

$$\left(x^2+1\right)y''-10xy'+28y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.329 (sec)

Writing the ode as

$$\left(x^2+1\right)y''-10xy'+28y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2+1 \\ B &= -10x \\ C &= 28 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{2x^2-33}{\left(x^2+1\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 2x^2-33 \\ t &= \left(x^2+1\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{2x^2-33}{\left(x^2+1\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.101: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (x^2+1)^2$. There is a pole at $x = i$ of order 2. There is a pole at $x = -i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{35}{4(x-i)^2} + \frac{35}{4(x+i)^2} + \frac{31i}{4(x-i)} - \frac{31i}{4(x+i)}$$

For the pole at $x = i$ let b be the coefficient of $\frac{1}{(x-i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{35}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{5}{2} \end{aligned}$$

For the pole at $x = -i$ let b be the coefficient of $\frac{1}{(x+i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{35}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{5}{2} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{2x^2 - 33}{(x^2+1)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = 2$. Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= 0\\ \alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = 2\\ \alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -1\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{2x^2 - 33}{(x^2+1)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
i	2	0	$\frac{7}{2}$	$-\frac{5}{2}$
$-i$	2	0	$\frac{7}{2}$	$-\frac{5}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	2	-1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = 2$ then

$$\begin{aligned}d &= \alpha_\infty^+ - \left(\alpha_{c_1}^- + \alpha_{c_2}^+\right)\\ &= 2 - (1)\\ &= 1\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x-c_2}\right) + (+)[\sqrt{r}]_\infty\\ &= -\frac{5}{2\,(x-i)} + \frac{7}{2\,(x+i)} + (0)\\ &= -\frac{5}{2\,(x-i)} + \frac{7}{2\,(x+i)}\\ &= \frac{x-6i}{x^2+1}\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{5}{2(x-i)} + \frac{7}{2(x+i)}\right)(1) + \left(\left(\frac{5}{2(x-i)^2} - \frac{7}{2(x+i)^2}\right) + \left(-\frac{5}{2(x-i)} + \frac{7}{2(x+i)}\right)^2 - \left(\frac{2x^{2}}{(x^{2}}\right.\right.$$
$$-\frac{2(6i+a_0)(x^{2}}{(-x+i)^2(x}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = -6i\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x - 6i$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= pe^{\int \omega\,dx} \\
&= (x-6i)\,e^{\int \left(-\frac{5}{2(x-i)} + \frac{7}{2(x+i)}\right)dx} \\
&= (x-6i)\,e^{\frac{\ln(x^2+1)}{2} - 6i\arctan(x)} \\
&= \frac{(-x+6i)(x^2+1)^{7/2}}{(-x+i)^6}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-10x}{x^2+1}\,dx} \\
&= z_1 e^{\frac{5\ln(x^2+1)}{2}} \\
&= z_1\left((x^2+1)^{5/2}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{(x^2+1)^6(-x+6i)}{(-x+i)^6}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-10x}{x^2+1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{5\ln(x^2+1)}}{(y_1)^2}\,dx \\
&= y_1\left(\frac{724i}{2401(x+i)^4} - \frac{16i}{147(x+i)^6} - \frac{3125i}{117649(x+i)^2} + \frac{496}{1715(x+i)^5} - \frac{7432}{50421(x+i)^3}\right. \\
&\qquad \left. - \frac{3125}{823543(x+i)} + \frac{3125}{823543(x-6i)}\right)
\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1y_1 + c_2y_2 \\
&= c_1\left(\frac{(x^2+1)^6(-x+6i)}{(-x+i)^6}\right) \\
&+ c_2\left(\frac{(x^2+1)^6(-x+6i)}{(-x+i)^6}\left(\frac{724i}{2401(x+i)^4} - \frac{16i}{147(x+i)^6} - \frac{3125i}{117649(x+i)^2}\right.\right. \\
&\left.\left.+ \frac{496}{1715(x+i)^5} - \frac{7432}{50421(x+i)^3} - \frac{3125}{823543(x+i)} + \frac{3125}{823543(x-6i)}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

2.1.57 Problem 59

Internal problem ID [9229]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 59
Date solved : `Monday, January 27, 2025 at 05:52:19 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$y'' + xy' + 2y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.207 (sec)

Writing the ode as

$$y'' + xy' + 2y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= x \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 - 6}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2 - 6 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2}{4} - \frac{3}{2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.102: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 2 \\ &= -2 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x}{2} - \frac{3}{2x} - \frac{9}{4x^3} - \frac{27}{4x^5} - \frac{405}{16x^7} - \frac{1701}{16x^9} - \frac{15309}{32x^{11}} - \frac{72171}{32x^{13}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= \frac{x}{2}\end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{x^2}{4}$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned}r &= \frac{s}{t} \\ &= \frac{x^2 - 6}{4} \\ &= Q + \frac{R}{4} \\ &= \left(\frac{x^2}{4} - \frac{3}{2}\right) + (0) \\ &= \frac{x^2}{4} - \frac{3}{2}\end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is $-\frac{3}{2}$. Now b can be found.

$$\begin{aligned}b &= \left(-\frac{3}{2}\right) - (0) \\ &= -\frac{3}{2}\end{aligned}$$

Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= \frac{x}{2} \\ \alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{3}{2}}{\frac{1}{2}} - 1\right) &&= -2 \\ \alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{3}{2}}{\frac{1}{2}} - 1\right) &&= 1\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2}{4} - \frac{3}{2}$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
-2	$\frac{x}{2}$	-2	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$, and since there are no poles then

$$\begin{aligned} d &= \alpha_\infty^- \\ &= 1 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= (-)[\sqrt{r}]_\infty \\ &= 0 + (-)\left(\frac{x}{2}\right) \\ &= -\frac{x}{2} \\ &= -\frac{x}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(-\frac{x}{2}\right)(1) + \left(\left(-\frac{1}{2}\right) + \left(-\frac{x}{2}\right)^2 - \left(\frac{x^2}{4} - \frac{3}{2}\right)\right) &= 0 \\ a_0 &= 0 \end{aligned}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= pe^{\int \omega\, dx} \\ &= (x)\, e^{\int -\frac{x}{2} dx} \\ &= (x)\, e^{-\frac{x^2}{4}} \\ &= x\, e^{-\frac{x^2}{4}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{x}{1}\, dx} \\ &= z_1 e^{-\frac{x^2}{4}} \\ &= z_1\left(e^{-\frac{x^2}{4}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-\frac{x^2}{2}} x$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x}{1}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-\frac{x^2}{2}}}{(y_1)^2}\, dx \\
&= y_1 \left(-\frac{\mathrm{e}^{\frac{x^2}{2}}}{x} - \frac{i\sqrt{\pi}\,\sqrt{2}\,\mathrm{erf}\left(\frac{i\sqrt{2}\,x}{2}\right)}{2} \right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-\frac{x^2}{2}} x \right) + c_2 \left(\mathrm{e}^{-\frac{x^2}{2}} x \left(-\frac{\mathrm{e}^{\frac{x^2}{2}}}{x} - \frac{i\sqrt{\pi}\,\sqrt{2}\,\mathrm{erf}\left(\frac{i\sqrt{2}\,x}{2}\right)}{2} \right) \right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$\frac{d^2}{dx^2}y(x) + x\left(\frac{d}{dx}y(x)\right) + 2y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^k$

☐ Rewrite DE with series expansions

  ◦ Convert $x \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion

  $x \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k k\, x^k$

  ◦ Convert $\frac{d^2}{dx^2}y(x)$ to series expansion

  $\frac{d^2}{dx^2}y(x) = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$

  ◦ Shift index using $k- >k+2$

  $\frac{d^2}{dx^2}y(x) = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$

  Rewrite DE with series expansions

  $\sum_{k=0}^{\infty} \left(a_{k+2}(k+2)\,(k+1) + a_k(k+2)\right) x^k = 0$

- Each term in the series must be 0, giving the recursion relation

$(k+2)(ka_{k+2}+a_k+a_{k+2})=0$

- Recursion relation that defines the series solution to the ODE

$$\left[y(x)=\sum_{k=0}^{\infty} a_k x^k, a_{k+2}=-\frac{a_k}{k+1}\right]$$

2.1.58 Problem 60

Internal problem ID [9230]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 60
Date solved : `Monday, January 27, 2025 at 05:52:20 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$\left(2x^2+1\right)y''-9xy'-6y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.470 (sec)

Writing the ode as

$$\left(2x^2+1\right)y''-9xy'-6y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A&=2x^2+1\\ B&=-9x\\ C&=-6 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r&=\frac{s}{t}\\ &=\frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{165x^2+6}{4\left(2x^2+1\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s&=165x^2+6\\ t&=4\left(2x^2+1\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{165x^2+6}{4\left(2x^2+1\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.104: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(2x^2 + 1)^2$. There is a pole at $x = \frac{i\sqrt{2}}{2}$ of order 2. There is a pole at $x = -\frac{i\sqrt{2}}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{153}{64 \left(x - \frac{i\sqrt{2}}{2}\right)^2} + \frac{153}{64 \left(x + \frac{i\sqrt{2}}{2}\right)^2} - \frac{177i\sqrt{2}}{64 \left(x - \frac{i\sqrt{2}}{2}\right)} + \frac{177i\sqrt{2}}{64 \left(x + \frac{i\sqrt{2}}{2}\right)}$$

For the pole at $x = \frac{i\sqrt{2}}{2}$ let b be the coefficient of $\frac{1}{\left(x - \frac{i\sqrt{2}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{153}{64}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{17}{8} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{9}{8} \end{aligned}$$

For the pole at $x = -\frac{i\sqrt{2}}{2}$ let b be the coefficient of $\frac{1}{\left(x+\frac{i\sqrt{2}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{153}{64}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{17}{8} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{9}{8}
\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{165x^2+6}{4\left(2x^2+1\right)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{165}{16}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{15}{4} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{11}{4}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{165x^2+6}{4\left(2x^2+1\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
$\frac{i\sqrt{2}}{2}$	2	0	$\frac{17}{8}$	$-\frac{9}{8}$
$-\frac{i\sqrt{2}}{2}$	2	0	$\frac{17}{8}$	$-\frac{9}{8}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{15}{4}$	$-\frac{11}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{15}{4}$ then

$$\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^- + \alpha_{c_2}^-\right) \\
&= \frac{15}{4} - \left(-\frac{9}{4}\right) \\
&= 6
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2}\right) + (+)[\sqrt{r}]_\infty \\ &= -\frac{9}{8\left(x-\frac{i\sqrt{2}}{2}\right)} - \frac{9}{8\left(x+\frac{i\sqrt{2}}{2}\right)} + (0) \\ &= -\frac{9}{8\left(x-\frac{i\sqrt{2}}{2}\right)} - \frac{9}{8\left(x+\frac{i\sqrt{2}}{2}\right)} \\ &= -\frac{9x}{4x^2+2}\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 6$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = x^6 + a_5x^5 + a_4x^4 + a_3x^3 + a_2x^2 + a_1x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(30x^4 + 20x^3a_5 + 12x^2a_4 + 6xa_3 + 2a_2) + 2\left(-\frac{9}{8\left(x-\frac{i\sqrt{2}}{2}\right)} - \frac{9}{8\left(x+\frac{i\sqrt{2}}{2}\right)}\right)(6x^5 + 5x^4a_5 + 4x^3a_4 + 3x^2a_3$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\left\{a_0 = \frac{1}{3}, a_1 = 0, a_2 = 1, a_3 = 0, a_4 = \frac{5}{3}, a_5 = 0\right\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^6 + \frac{5}{3}x^4 + x^2 + \frac{1}{3}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}z_1(x) &= pe^{\int \omega\, dx} \\ &= \left(x^6 + \frac{5}{3}x^4 + x^2 + \frac{1}{3}\right) \mathrm{e}^{\int \left(-\frac{9}{8\left(x-\frac{i\sqrt{2}}{2}\right)} - \frac{9}{8\left(x+\frac{i\sqrt{2}}{2}\right)}\right) dx} \\ &= \left(x^6 + \frac{5}{3}x^4 + x^2 + \frac{1}{3}\right) \frac{1}{\left((i\sqrt{2}-2x)\,(2x+i\sqrt{2})\right)^{9/8}} \\ &= \frac{-3x^6 - 5x^4 - 3x^2 - 1}{(-4x^2-2)^{1/8}\,(12x^2+6)}\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-9x}{2x^2+1}\, dx} \\ &= z_1 e^{\frac{9\ln(2x^2+1)}{8}} \\ &= z_1\left((2x^2+1)^{9/8}\right)\end{aligned}$$

Which simplifies to

$$y_1 = -\frac{2^{7/8}(4x^2+2)^{1/8}(3x^6+5x^4+3x^2+1)}{12(-4x^2-2)^{1/8}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-9x}{2x^2+1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{\frac{9\ln(2x^2+1)}{4}}}{(y_1)^2}\,dx \\ &= y_1 \left(\int \frac{36(2x^2+1)^{9/4}\, 2^{1/4}(-4x^2-2)^{1/4}}{(4x^2+2)^{1/4}(3x^6+5x^4+3x^2+1)^2}dx\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1y_1 + c_2y_2 \\ &= c_1\left(-\frac{2^{7/8}(4x^2+2)^{1/8}(3x^6+5x^4+3x^2+1)}{12(-4x^2-2)^{1/8}}\right) + c_2\left(-\frac{2^{7/8}(4x^2+2)^{1/8}(3x^6+5x^4+3x^2+1)}{12(-4x^2-2)^{1/8}}\left(\int \frac{36\cdots}{(4x^2\cdots}\right.\right. \end{aligned}$$

Will add steps showing solving for IC soon.

2.1.59 Problem 61

Internal problem ID [9231]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 61
Date solved : `Monday, January 27, 2025 at 05:52:21 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$\left(2x^2-8x+11\right)y''-16(x-2)\,y'+36y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.599 (sec)

Writing the ode as

$$\left(2x^2-8x+11\right)y''+(-16x+32)\,y'+36y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A&=2x^2-8x+11\\ B&=-16x+32\\ C&=36 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r&=\frac{s}{t}\\ &=\frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{8x^2-32x-100}{\left(2x^2-8x+11\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s&=8x^2-32x-100\\ t&=\left(2x^2-8x+11\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{8x^2-32x-100}{\left(2x^2-8x+11\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.105: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (2x^2 - 8x + 11)^2$. There is a pole at $x = 2 + \frac{i\sqrt{6}}{2}$ of order 2. There is a pole at $x = 2 - \frac{i\sqrt{6}}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{6}{\left(x - 2 - \frac{i\sqrt{6}}{2}\right)^2} + \frac{6}{\left(x - 2 + \frac{i\sqrt{6}}{2}\right)^2} + \frac{5i\sqrt{6}}{3\left(x - 2 - \frac{i\sqrt{6}}{2}\right)} - \frac{5i\sqrt{6}}{3\left(x - 2 + \frac{i\sqrt{6}}{2}\right)}$$

For the pole at $x = 2 + \frac{i\sqrt{6}}{2}$ let b be the coefficient of $\frac{1}{\left(x-2-\frac{i\sqrt{6}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 6$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = 3 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -2 \end{aligned}$$

For the pole at $x = 2 - \frac{i\sqrt{6}}{2}$ let b be the coefficient of $\frac{1}{\left(x-2+\frac{i\sqrt{6}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 6$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 3 \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -2
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = \frac{8x^2 - 32x - 100}{(2x^2 - 8x + 11)^2}
$$

Since the $\gcd(s,t) = 1$. This gives $b = 2$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -1
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{8x^2 - 32x - 100}{(2x^2 - 8x + 11)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
$2 + \frac{i\sqrt{6}}{2}$	2	0	3	-2
$2 - \frac{i\sqrt{6}}{2}$	2	0	3	-2

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	2	-1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = 2$ then

$$
\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^- + \alpha_{c_2}^+\right) \\
&= 2 - (1) \\
&= 1
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

Substituting the above values in the above results in

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x-c_2}\right) + (+)[\sqrt{r}]_\infty \\
&= -\frac{2}{x-2-\frac{i\sqrt{6}}{2}} + \frac{3}{x-2+\frac{i\sqrt{6}}{2}} + (0) \\
&= -\frac{2}{x-2-\frac{i\sqrt{6}}{2}} + \frac{3}{x-2+\frac{i\sqrt{6}}{2}} \\
&= \frac{-5i\sqrt{6}+2x-4}{2x^2-8x+11}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = x + a_0 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(0) + 2\left(-\frac{2}{x-2-\frac{i\sqrt{6}}{2}} + \frac{3}{x-2+\frac{i\sqrt{6}}{2}}\right)(1) + \left(\left(\frac{2}{\left(x-2-\frac{i\sqrt{6}}{2}\right)^2} - \frac{3}{\left(x-2+\frac{i\sqrt{6}}{2}\right)^2}\right) + \left(-\frac{2}{x-2-\frac{i\sqrt{6}}{2}} +\right.\right.
$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$
\left\{a_0 = -\frac{5i\sqrt{6}}{2} - 2\right\}
$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$
p(x) = x - 2 - \frac{5i\sqrt{6}}{2}
$$

Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \left(x - 2 - \frac{5i\sqrt{6}}{2}\right) e^{\int \left(-\frac{2}{x-2-\frac{i\sqrt{6}}{2}} + \frac{3}{x-2+\frac{i\sqrt{6}}{2}}\right) dx} \\
&= \left(x - 2 - \frac{5i\sqrt{6}}{2}\right) e^{\frac{\ln\left(4x^2-16x+22\right)}{2} - 5i \arctan\left(\frac{(2x-4)\sqrt{6}}{6}\right)} \\
&= \frac{9\left(5\sqrt{6}+2ix-4i\right)\left(2x^2-8x+11\right)^3 \sqrt{6}}{2\left(-x\sqrt{6}+2\sqrt{6}+3i\right)^5}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-16x+32}{2x^2-8x+11} \, dx} \\
&= z_1 e^{2\ln\left(2x^2-8x+11\right)} \\
&= z_1 \left(\left(2x^2-8x+11\right)^2\right)
\end{aligned}
$$

Which simplifies to

$$y_1 = -\frac{9(2x^2-8x+11)^5 \left(5\sqrt{6}+2ix-4i\right)\sqrt{6}}{2\left(x\sqrt{6}-2\sqrt{6}-3i\right)^5}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-16x+32}{2x^2-8x+11}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{4\ln(2x^2-8x+11)}}{(y_1)^2}\,dx \\
&= y_1 \left(-\frac{10i\sqrt{6}}{27\left(2x-4+i\sqrt{6}\right)^4} + \frac{8i\sqrt{6}}{729\left(2x-4+i\sqrt{6}\right)^2} - \frac{16}{15\left(2x-4+i\sqrt{6}\right)^5} \right. \\
&\quad \left. + \frac{22}{81\left(2x-4+i\sqrt{6}\right)^3} + \frac{4}{2187\left(2x-4+i\sqrt{6}\right)} - \frac{4}{2187\left(-5i\sqrt{6}+2x-4\right)}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(-\frac{9(2x^2-8x+11)^5 \left(5\sqrt{6}+2ix-4i\right)\sqrt{6}}{2\left(x\sqrt{6}-2\sqrt{6}-3i\right)^5}\right) \\
&\quad + c_2 \left(-\frac{9(2x^2-8x+11)^5 \left(5\sqrt{6}+2ix-4i\right)\sqrt{6}}{2\left(x\sqrt{6}-2\sqrt{6}-3i\right)^5} \left(-\frac{10i\sqrt{6}}{27\left(2x-4+i\sqrt{6}\right)^4} \right.\right. \\
&\quad + \frac{8i\sqrt{6}}{729\left(2x-4+i\sqrt{6}\right)^2} - \frac{16}{15\left(2x-4+i\sqrt{6}\right)^5} + \frac{22}{81\left(2x-4+i\sqrt{6}\right)^3} \\
&\quad \left.\left. + \frac{4}{2187\left(2x-4+i\sqrt{6}\right)} - \frac{4}{2187\left(-5i\sqrt{6}+2x-4\right)}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$(2x^2-8x+11)\left(\frac{d^2}{dx^2}y(x)\right) - 16(x-2)\left(\frac{d}{dx}y(x)\right) + 36y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{36y(x)}{2x^2-8x+11} + \frac{16(x-2)\left(\frac{d}{dx}y(x)\right)}{2x^2-8x+11}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lir

  $\frac{d^2}{dx^2}y(x) - \frac{16(x-2)\left(\frac{d}{dx}y(x)\right)}{2x^2-8x+11} + \frac{36y(x)}{2x^2-8x+11} = 0$

□ Check to see if x_0 is a regular singular point

- Define functions

  $\left[P_2(x) = -\frac{16(x-2)}{2x^2-8x+11}, P_3(x) = \frac{36}{2x^2-8x+11}\right]$

- $\left(x - 2 + \frac{I\sqrt{6}}{2}\right) \cdot P_2(x)$ is analytic at $x = 2 - \frac{I\sqrt{6}}{2}$

  $\left(\left(x - 2 + \frac{I\sqrt{6}}{2}\right) \cdot P_2(x)\right)\bigg|_{x=2-\frac{I\sqrt{6}}{2}} = 0$

- $\left(x - 2 + \frac{I\sqrt{6}}{2}\right)^2 \cdot P_3(x)$ is analytic at $x = 2 - \frac{I\sqrt{6}}{2}$

  $\left(\left(x - 2 + \frac{I\sqrt{6}}{2}\right)^2 \cdot P_3(x)\right)\bigg|_{x=2-\frac{I\sqrt{6}}{2}} = 0$

- $x = 2 - \frac{I\sqrt{6}}{2}$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = 2 - \frac{I\sqrt{6}}{2}$

- Multiply by denominators

  $(2x^2 - 8x + 11)\left(\frac{d^2}{dx^2}y(x)\right) + (-16x + 32)\left(\frac{d}{dx}y(x)\right) + 36y(x) = 0$

- Change variables using $x = u + 2 - \frac{I\sqrt{6}}{2}$ so that the regular singular point is at $u = 0$

  $(2u^2 - 2\,Iu\sqrt{6})\left(\frac{d^2}{du^2}y(u)\right) + (-16u + 8\,I\sqrt{6})\left(\frac{d}{du}y(u)\right) + 36y(u) = 0$

- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..1$

  $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,u^{k+r-1+m}$

- Shift index using $k->k+1-m$

  $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,u^{k+r}$

- Convert $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m = 1..2$

  $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\,u^{k+r-2+m}$

- Shift index using $k->k+2-m$

  $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\,u^{k+r}$

  Rewrite ODE with series expansions

  $-2\,I\sqrt{6}\,r(r-5)\,a_0u^{-1+r} + \left(\sum_{k=0}^{\infty} \left(-2\,I\sqrt{6}\,(k+1+r)(k-4+r)\,a_{k+1} + 2a_k(k+r-3)(k+r-6)\right)\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $-2\,I\sqrt{6}\,r(r-5) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{0, 5\}$

- Each term in the series must be 0, giving the recursion relation

  $-2\,I\sqrt{6}\,(k+1+r)(k-4+r)\,a_{k+1} + 2a_k(k+r-3)(k+r-6) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+1} = \frac{-\frac{I}{6}a_k(k^2+2kr+r^2-9k-9r+18)\sqrt{6}}{k^2+2kr+r^2-3k-3r-4}$

- Recursion relation for $r = 0$; series terminates at $k = 3$

  $a_{k+1} = \frac{-\frac{I}{6}a_k(k^2-9k+18)\sqrt{6}}{k^2-3k-4}$

- Apply recursion relation for $k = 0$
  $a_1 = \frac{3 I}{4} a_0 \sqrt{6}$
- Apply recursion relation for $k = 1$
  $a_2 = \frac{5 I}{18} a_1 \sqrt{6}$
- Express in terms of a_0
  $a_2 = -\frac{5 a_0}{4}$
- Apply recursion relation for $k = 2$
  $a_3 = \frac{I}{9} a_2 \sqrt{6}$
- Express in terms of a_0
  $a_3 = -\frac{5 I}{36} a_0 \sqrt{6}$
- Terminating series solution of the ODE for $r = 0$. Use reduction of order to find the second li
  $y(u) = a_0 \cdot \left(1 + \frac{3 I \sqrt{6}\, u}{4} - \frac{5 u^2}{4} - \frac{5 I \sqrt{6}\, u^3}{36}\right)$
- Revert the change of variables $u = x - 2 + \frac{I \sqrt{6}}{2}$
  $\left[y(x) = -\frac{I}{72} a_0 \sqrt{6}\, (10 x^3 - 60 x^2 + 111 x - 62)\right]$
- Recursion relation for $r = 5$; series terminates at $k = 1$
  $a_{k+1} = \frac{-\frac{I}{6} a_k (k^2+k-2) \sqrt{6}}{k^2+7k+6}$
- Apply recursion relation for $k = 0$
  $a_1 = \frac{I}{18} a_0 \sqrt{6}$
- Terminating series solution of the ODE for $r = 5$. Use reduction of order to find the second li
  $y(u) = a_0 \cdot \left(1 + \frac{I \sqrt{6}\, u}{18}\right)$
- Revert the change of variables $u = x - 2 + \frac{I \sqrt{6}}{2}$
  $\left[y(x) = a_0 \left(\frac{5}{6} + \frac{I(x-2)\sqrt{6}}{18}\right)\right]$
- Combine solutions and rename parameters
  $\left[y(x) = -\frac{I a_0 \sqrt{6}\, (10 x^3 - 60 x^2 + 111 x - 62)}{72} + b_0 \left(\frac{5}{6} + \frac{I(x-2)\sqrt{6}}{18}\right)\right]$

Solve

$$y'' + (x-3)\,y' + 3y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.282 (sec)

Writing the ode as

$$y'' + (x-3)\,y' + 3y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= x-3 \\ C &= 3 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 - 6x - 1}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2 - 6x - 1 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{1}{4} + \frac{1}{4}x^2 - \frac{3}{2}x\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.107: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 2 \\ &= -2 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x}{2} - \frac{3}{2} - \frac{5}{2x} - \frac{15}{2x^2} - \frac{115}{4x^3} - \frac{495}{4x^4} - \frac{2285}{4x^5} - \frac{11055}{4x^6} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= \frac{x}{2} - \frac{3}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}x^2 - \frac{3}{2}x + \frac{9}{4}$$

This shows that the coefficient of 1 in the above is $\frac{9}{4}$. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 - 6x - 1}{4} \\ &= Q + \frac{R}{4} \\ &= \left(-\frac{1}{4} + \frac{1}{4}x^2 - \frac{3}{2}x\right) + (0) \\ &= -\frac{1}{4} + \frac{1}{4}x^2 - \frac{3}{2}x \end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is $-\frac{1}{4}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{1}{4}\right) - \left(\frac{9}{4}\right) \\ &= -\frac{5}{2} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{x}{2} - \frac{3}{2} \\ \alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-\frac{5}{2}}{\frac{1}{2}} - 1\right) &= -3 \\ \alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-\frac{5}{2}}{\frac{1}{2}} - 1\right) &= 2 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = -\frac{1}{4} + \frac{1}{4}x^2 - \frac{3}{2}x$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
-2	$\frac{x}{2} - \frac{3}{2}$	-3	2

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 2$, and since there are no poles then

$$\begin{aligned} d &= \alpha_\infty^- \\ &= 2 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= (-)[\sqrt{r}]_\infty \\ &= 0 + (-)\left(\frac{x}{2} - \frac{3}{2}\right) \\ &= \frac{3}{2} - \frac{x}{2} \\ &= \frac{3}{2} - \frac{x}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 2$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}$$

Let

$$p(x) = x^2 + a_1 x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(2) + 2\left(\frac{3}{2} - \frac{x}{2}\right)(2x + a_1) + \left(\left(-\frac{1}{2}\right) + \left(\frac{3}{2} - \frac{x}{2}\right)^2 - \left(-\frac{1}{4} + \frac{1}{4}x^2 - \frac{3}{2}x\right)\right) = 0$$

$$(x+3)\,a_1 + 6x + 2a_0 + 2 = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 8, a_1 = -6\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^2 - 6x + 8$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega\,dx} \\ &= \left(x^2 - 6x + 8\right) e^{\int \left(\frac{3}{2} - \frac{x}{2}\right)dx} \\ &= \left(x^2 - 6x + 8\right) e^{\frac{3}{2}x - \frac{1}{4}x^2} \\ &= \left(x^2 - 6x + 8\right) e^{-\frac{x(-6+x)}{4}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{x-3}{1}\,dx} \\ &= z_1 e^{\frac{3}{2}x - \frac{1}{4}x^2} \\ &= z_1\left(e^{-\frac{x(-6+x)}{4}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-\frac{x(-6+x)}{2}} \left(x^2 - 6x + 8\right)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{x-3}{1}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-\frac{1}{2}x^2+3x}}{(y_1)^2}\, dx \\ &= y_1 \left(\int \frac{\mathrm{e}^{-\frac{1}{2}x^2+3x} \mathrm{e}^{x(-6+x)}}{(x^2-6x+8)^2} dx \right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\mathrm{e}^{-\frac{x(-6+x)}{2}} (x^2 - 6x + 8) \right) + c_2 \left(\mathrm{e}^{-\frac{x(-6+x)}{2}} (x^2 - 6x + 8) \left(\int \frac{\mathrm{e}^{-\frac{1}{2}x^2+3x} \mathrm{e}^{x(-6+x)}}{(x^2-6x+8)^2} dx \right) \right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$\frac{d^2}{dx^2}y(x) + (x-3)\left(\frac{d}{dx}y(x)\right) + 3y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^k$

- □ Rewrite DE with series expansions

  - Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m = 0..1$

    $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=\max(0,1-m)}^{\infty} a_k k\, x^{k-1+m}$

  - Shift index using $k- >k+1-m$

    $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=\max(0,1-m)+m-1}^{\infty} a_{k+1-m}(k+1-m)\, x^k$

  - Convert $\frac{d^2}{dx^2}y(x)$ to series expansion

    $\frac{d^2}{dx^2}y(x) = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$

  - Shift index using $k- >k+2$

    $\frac{d^2}{dx^2}y(x) = \sum_{k=0}^{\infty} a_{k+2}(k+2)(k+1)\, x^k$

  Rewrite DE with series expansions

$$\sum_{k=0}^{\infty} \left(a_{k+2}(k+2)\,(k+1) - 3a_{k+1}(k+1) + a_k(k+3)\right) x^k = 0$$

- Each term in the series must be 0, giving the recursion relation
$$k^2 a_{k+2} + \left(a_k - 3a_{k+1} + 3a_{k+2}\right) k + 3a_k - 3a_{k+1} + 2a_{k+2} = 0$$
- Recursion relation that defines the series solution to the ODE
$$\left[y(x) = \sum_{k=0}^{\infty} a_k x^k, a_{k+2} = -\frac{a_k k - 3a_{k+1}k + 3a_k - 3a_{k+1}}{k^2+3k+2}\right]$$

2.1.61 Problem 63

Internal problem ID [9233]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 63
Date solved : `Monday, January 27, 2025 at 05:52:22 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$\left(x^2-8x+14\right) y''-8(x-4)\, y'+20y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.285 (sec)

Writing the ode as

$$\left(x^2-8x+14\right) y''+(-8x+32)\, y'+20y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A&=x^2-8x+14\\ B&=-8x+32\\ C&=20 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r&=\frac{s}{t} \\ &=\frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{48}{\left(x^2-8x+14\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s&=48\\ t&=\left(x^2-8x+14\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{48}{\left(x^2-8x+14\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.109: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 0 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (x^2 - 8x + 14)^2$. There is a pole at $x = 4 + \sqrt{2}$ of order 2. There is a pole at $x = 4 - \sqrt{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{6}{\left(x - 4 + \sqrt{2}\right)^2} + \frac{6}{\left(x - 4 - \sqrt{2}\right)^2} + \frac{3\sqrt{2}}{x - 4 + \sqrt{2}} - \frac{3\sqrt{2}}{x - 4 - \sqrt{2}}$$

For the pole at $x = 4 + \sqrt{2}$ let b be the coefficient of $\frac{1}{\left(x-4-\sqrt{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 6$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 3 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -2 \end{aligned}$$

For the pole at $x = 4 - \sqrt{2}$ let b be the coefficient of $\frac{1}{\left(x-4+\sqrt{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 6$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 3 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -2 \end{aligned}$$

Since the order of r at ∞ is $4 > 2$ then

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= 0 \\
\alpha_\infty^{-} &= 1
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{48}{(x^2 - 8x + 14)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
$4+\sqrt{2}$	2	0	3	-2
$4-\sqrt{2}$	2	0	3	-2

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = 1$ then

$$
\begin{aligned}
d &= \alpha_\infty^{-} - \left(\alpha_{c_1}^{-} + \alpha_{c_2}^{+}\right) \\
&= 1 - (1) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x-c_1} \right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{+}}{x-c_2} \right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{2}{x-4-\sqrt{2}} + \frac{3}{x-4+\sqrt{2}} + (-)(0) \\
&= -\frac{2}{x-4-\sqrt{2}} + \frac{3}{x-4+\sqrt{2}} \\
&= \frac{x-4-5\sqrt{2}}{x^2-8x+14}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(-\frac{2}{x-4-\sqrt{2}}+\frac{3}{x-4+\sqrt{2}}\right)(0)+\left(\left(\frac{2}{\left(x-4-\sqrt{2}\right)^{2}}-\frac{3}{\left(x-4+\sqrt{2}\right)^{2}}\right)+\left(-\frac{2}{x-4-\sqrt{2}}+\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z''=rz$ is

$$\begin{aligned}z_1(x)&=pe^{\int \omega\,dx}\\&=\mathrm{e}^{\int\left(-\frac{2}{x-4-\sqrt{2}}+\frac{3}{x-4+\sqrt{2}}\right)dx}\\&=\frac{\left(x-4+\sqrt{2}\right)^{3}}{\left(-x+4+\sqrt{2}\right)^{2}}\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}y_1&=z_1e^{\int -\frac{1}{2}\frac{B}{A}\,dx}\\&=z_1e^{-\int \frac{1}{2}\frac{-8x+32}{x^2-8x+14}\,dx}\\&=z_1e^{2\ln(x^2-8x+14)}\\&=z_1\left(\left(x^2-8x+14\right)^2\right)\end{aligned}$$

Which simplifies to

$$y_1=\frac{\left(x^2-8x+14\right)^2\left(x-4+\sqrt{2}\right)^{3}}{\left(-x+4+\sqrt{2}\right)^{2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2=y_1\int\frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}y_2&=y_1\int\frac{e^{\int -\frac{-8x+32}{x^2-8x+14}\,dx}}{(y_1)^2}\,dx\\&=y_1\int\frac{e^{4\ln(x^2-8x+14)}}{(y_1)^2}\,dx\\&=y_1\left(-\frac{1}{x-4+\sqrt{2}}-\frac{64}{5\left(x-4+\sqrt{2}\right)^{5}}+\frac{16\sqrt{2}}{\left(x-4+\sqrt{2}\right)^{4}}-\frac{16}{\left(x-4+\sqrt{2}\right)^{3}}\right.\\&\qquad\left.+\frac{4\sqrt{2}}{\left(x-4+\sqrt{2}\right)^{2}}\right)\end{aligned}$$

Therefore the solution is

$$\begin{aligned}y&=c_1y_1+c_2y_2\\&=c_1\left(\frac{\left(x^2-8x+14\right)^2\left(x-4+\sqrt{2}\right)^{3}}{\left(-x+4+\sqrt{2}\right)^{2}}\right)\\&\quad+c_2\left(\frac{\left(x^2-8x+14\right)^2\left(x-4+\sqrt{2}\right)^{3}}{\left(-x+4+\sqrt{2}\right)^{2}}\left(-\frac{1}{x-4+\sqrt{2}}-\frac{64}{5\left(x-4+\sqrt{2}\right)^{5}}\right.\right.\\&\qquad\left.\left.+\frac{16\sqrt{2}}{\left(x-4+\sqrt{2}\right)^{4}}-\frac{16}{\left(x-4+\sqrt{2}\right)^{3}}+\frac{4\sqrt{2}}{\left(x-4+\sqrt{2}\right)^{2}}\right)\right)\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$(x^2-8x+14)\left(\frac{d^2}{dx^2}y(x)\right)-8(-4+x)\left(\frac{d}{dx}y(x)\right)+20y(x)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x)=-\frac{20y(x)}{x^2-8x+14}+\frac{8(-4+x)\left(\frac{d}{dx}y(x)\right)}{x^2-8x+14}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x)-\frac{8(-4+x)\left(\frac{d}{dx}y(x)\right)}{x^2-8x+14}+\frac{20y(x)}{x^2-8x+14}=0$

- □ Check to see if x_0 is a regular singular point
  - Define functions

    $\left[P_2(x)=-\frac{8(-4+x)}{x^2-8x+14}, P_3(x)=\frac{20}{x^2-8x+14}\right]$

  - $(x-4+\sqrt{2})\cdot P_2(x)$ is analytic at $x=4-\sqrt{2}$

    $\left((x-4+\sqrt{2})\cdot P_2(x)\right)\Big|_{x=4-\sqrt{2}}=0$

  - $(x-4+\sqrt{2})^2\cdot P_3(x)$ is analytic at $x=4-\sqrt{2}$

    $\left((x-4+\sqrt{2})^2\cdot P_3(x)\right)\Big|_{x=4-\sqrt{2}}=0$

  - $x=4-\sqrt{2}$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=4-\sqrt{2}$

- Multiply by denominators

  $(x^2-8x+14)\left(\frac{d^2}{dx^2}y(x)\right)+(-8x+32)\left(\frac{d}{dx}y(x)\right)+20y(x)=0$

- Change variables using $x=u+4-\sqrt{2}$ so that the regular singular point is at $u=0$

  $(u^2-2u\sqrt{2})\left(\frac{d^2}{du^2}y(u)\right)+(-8u+8\sqrt{2})\left(\frac{d}{du}y(u)\right)+20y(u)=0$

- Assume series solution for $y(u)$

  $y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

- □ Rewrite ODE with series expansions
  - Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$

    $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,u^{k+r-1+m}$

  - Shift index using $k->k+1-m$

    $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,u^{k+r}$

  - Convert $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m=1..2$

    $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)(k+r-1)\,u^{k+r-2+m}$

  - Shift index using $k->k+2-m$

    $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=-2+m}^{\infty}a_{k+2-m}(k+2-m+r)(k+1-m+r)\,u^{k+r}$

  Rewrite ODE with series expansions

  $-2\sqrt{2}(r-5)ra_0u^{-1+r}+\left(\sum_{k=0}^{\infty}\left(-2\sqrt{2}(k+r-4)(k+1+r)a_{k+1}+a_k(k+r-4)(k+r-5)\right)u^{k+}\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $-2\sqrt{2}\,(r-5)\,r=0$
- Values of r that satisfy the indicial equation
  $r\in\{0,5\}$
- Each term in the series must be 0, giving the recursion relation
  $\left(-2a_{k+1}(k+1+r)\sqrt{2}+a_k(k+r-5)\right)(k+r-4)=0$
- Recursion relation that defines series solution to ODE
  $a_{k+1}=\frac{a_k(k+r-5)\sqrt{2}}{4(k+1+r)}$
- Recursion relation for $r=0$; series terminates at $k=5$
  $a_{k+1}=\frac{a_k(k-5)\sqrt{2}}{4(k+1)}$

Date solved : `Monday, January 27, 2025 at 05:52:23 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$\left(2x^2+4x+5\right)y''-20(x+1)\,y'+60y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.598 (sec)

Writing the ode as

$$\left(2x^2+4x+5\right)y''+(-20x-20)\,y'+60y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2x^2+4x+5 \\ B &= -20x-20 \\ C &= 60 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{-210}{\left(2x^2+4x+5\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -210 \\ t &= \left(2x^2+4x+5\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(-\frac{210}{\left(2x^2+4x+5\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.111: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 0 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (2x^2 + 4x + 5)^2$. There is a pole at $x = -1 + \frac{i\sqrt{6}}{2}$ of order 2. There is a pole at $x = -1 - \frac{i\sqrt{6}}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{35}{4\left(x + 1 - \frac{i\sqrt{6}}{2}\right)^2} + \frac{35}{4\left(x + 1 + \frac{i\sqrt{6}}{2}\right)^2} + \frac{35i\sqrt{6}}{12\left(x + 1 - \frac{i\sqrt{6}}{2}\right)} - \frac{35i\sqrt{6}}{12\left(x + 1 + \frac{i\sqrt{6}}{2}\right)}$$

For the pole at $x = -1 + \frac{i\sqrt{6}}{2}$ let b be the coefficient of $\frac{1}{\left(x+1-\frac{i\sqrt{6}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{35}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{7}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{5}{2} \end{aligned}$$

For the pole at $x = -1 - \frac{i\sqrt{6}}{2}$ let b be the coefficient of $\frac{1}{\left(x+1+\frac{i\sqrt{6}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{35}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^{+} &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{2} \\
\alpha_c^{-} &= \frac{1}{2} - \sqrt{1+4b} = -\frac{5}{2}
\end{aligned}
$$

Since the order of r at ∞ is $4 > 2$ then

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= 0 \\
\alpha_\infty^{-} &= 1
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = -\frac{210}{(2x^2+4x+5)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
$-1+\frac{i\sqrt{6}}{2}$	2	0	$\frac{7}{2}$	$-\frac{5}{2}$
$-1-\frac{i\sqrt{6}}{2}$	2	0	$\frac{7}{2}$	$-\frac{5}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = 1$ then

$$
\begin{aligned}
d &= \alpha_\infty^{-} - \left(\alpha_{c_1}^{-} + \alpha_{c_2}^{+}\right) \\
&= 1 - (1) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x-c_1} \right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{+}}{x-c_2} \right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{5}{2\left(x+1-\frac{i\sqrt{6}}{2}\right)} + \frac{7}{2\left(x+1+\frac{i\sqrt{6}}{2}\right)} + (-)(0) \\
&= -\frac{5}{2\left(x+1-\frac{i\sqrt{6}}{2}\right)} + \frac{7}{2\left(x+1+\frac{i\sqrt{6}}{2}\right)} \\
&= \frac{-6i\sqrt{6}+2x+2}{2x^2+4x+5}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{5}{2\left(x+1-\frac{i\sqrt{6}}{2}\right)} + \frac{7}{2\left(x+1+\frac{i\sqrt{6}}{2}\right)}\right)(0) + \left(\left(\frac{5}{2\left(x+1-\frac{i\sqrt{6}}{2}\right)^2} - \frac{7}{2\left(x+1+\frac{i\sqrt{6}}{2}\right)^2}\right) + \left(-\frac{}{2}\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(-\frac{5}{2\left(x+1-\frac{i\sqrt{6}}{2}\right)} + \frac{7}{2\left(x+1+\frac{i\sqrt{6}}{2}\right)}\right) dx} \\
&= \frac{27\sqrt{2}\left(2x^2+4x+5\right)^{7/2}}{\left(3+i\left(x+1\right)\sqrt{6}\right)^6}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-20x-20}{2x^2+4x+5} \, dx} \\
&= z_1 e^{\frac{5\ln\left(2x^2+4x+5\right)}{2}} \\
&= z_1 \left(\left(2x^2+4x+5\right)^{5/2}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = -\frac{\left(2x^2+4x+5\right)^6 \sqrt{2}}{27\left(i - \frac{(x+1)\sqrt{2}\sqrt{3}}{3}\right)^6}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-20x-20}{2x^2+4x+5} \, dx}}{\left(y_1\right)^2} \, dx \\
&= y_1 \int \frac{e^{5\ln\left(2x^2+4x+5\right)}}{\left(y_1\right)^2} \, dx \\
&= y_1 \left(-\frac{\frac{1}{2}x^5 + \frac{5}{2}x^4 + \frac{5}{2}x^3 - \frac{5}{2}x^2 - \frac{31}{8}x - \frac{7}{8}}{2\left(x+1+\frac{i\sqrt{6}}{2}\right)^6}\right)
\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(-\frac{(2x^2+4x+5)^6 \sqrt{2}}{27 \left(i - \frac{(x+1)\sqrt{2}\sqrt{3}}{3}\right)^6} \right) \\
&\quad + c_2 \left(-\frac{(2x^2+4x+5)^6 \sqrt{2}}{27 \left(i - \frac{(x+1)\sqrt{2}\sqrt{3}}{3}\right)^6} \left(-\frac{\frac{1}{2}x^5 + \frac{5}{2}x^4 + \frac{5}{2}x^3 - \frac{5}{2}x^2 - \frac{31}{8}x - \frac{7}{8}}{2\left(x+1+\frac{i\sqrt{6}}{2}\right)^6} \right) \right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$(2x^2+4x+5)\left(\frac{d^2}{dx^2}y(x)\right) - 20(x+1)\left(\frac{d}{dx}y(x)\right) + 60y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{60y(x)}{2x^2+4x+5} + \frac{20(x+1)\left(\frac{d}{dx}y(x)\right)}{2x^2+4x+5}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x) - \frac{20(x+1)\left(\frac{d}{dx}y(x)\right)}{2x^2+4x+5} + \frac{60y(x)}{2x^2+4x+5} = 0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

    $\left[P_2(x) = -\frac{20(x+1)}{2x^2+4x+5}, P_3(x) = \frac{60}{2x^2+4x+5}\right]$

  ◦ $\left(x+1+\frac{\mathrm{I}\sqrt{6}}{2}\right) \cdot P_2(x)$ is analytic at $x = -1 - \frac{\mathrm{I}\sqrt{6}}{2}$

    $\left(\left(x+1+\frac{\mathrm{I}\sqrt{6}}{2}\right) \cdot P_2(x)\right)\Bigg|_{x=-1-\frac{\mathrm{I}\sqrt{6}}{2}} = 0$

  ◦ $\left(x+1+\frac{\mathrm{I}\sqrt{6}}{2}\right)^2 \cdot P_3(x)$ is analytic at $x = -1 - \frac{\mathrm{I}\sqrt{6}}{2}$

    $\left(\left(x+1+\frac{\mathrm{I}\sqrt{6}}{2}\right)^2 \cdot P_3(x)\right)\Bigg|_{x=-1-\frac{\mathrm{I}\sqrt{6}}{2}} = 0$

  ◦ $x = -1 - \frac{\mathrm{I}\sqrt{6}}{2}$ is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = -1 - \frac{\mathrm{I}\sqrt{6}}{2}$

- Multiply by denominators

  $(2x^2+4x+5)\left(\frac{d^2}{dx^2}y(x)\right) + (-20x-20)\left(\frac{d}{dx}y(x)\right) + 60y(x) = 0$

- Change variables using $x = u - 1 - \frac{\mathrm{I}\sqrt{6}}{2}$ so that the regular singular point is at $u = 0$

  $\left(2u^2 - 2\mathrm{I}u\sqrt{6}\right)\left(\frac{d^2}{du^2}y(u)\right) + \left(-20u + 10\mathrm{I}\sqrt{6}\right)\left(\frac{d}{du}y(u)\right) + 60y(u) = 0$

- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..1$

$$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, u^{k+r-1+m}$$

- Shift index using $k->k+1-m$

$$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$$

- Convert $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m = 1..2$

$$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, u^{k+r-2+m}$$

- Shift index using $k->k+2-m$

$$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\, u^{k+r}$$

Rewrite ODE with series expansions

$$-2\,\mathrm{I}\sqrt{6}\,(r-6)\, r a_0 u^{-1+r} + \left(\sum_{k=0}^{\infty} \left(-2\,\mathrm{I}\sqrt{6}\,(k+r-5)(k+1+r)\, a_{k+1} + 2a_k(k+r-5)(k+r-6)\right)\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$-2\,\mathrm{I}\sqrt{6}\,(r-6)\, r = 0$$

- Values of r that satisfy the indicial equation

$$r \in \{0, 6\}$$

- Each term in the series must be 0, giving the recursion relation

$$-2\left(\mathrm{I}a_{k+1}(k+1+r)\sqrt{6} - a_k(k+r-6)\right)(k+r-5) = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1} = \frac{-\frac{\mathrm{I}}{6}a_k(k+r-6)\sqrt{6}}{k+1+r}$$

- Recursion relation for $r = 0$; series terminates at $k = 6$

$$a_{k+1} = \frac{-\frac{\mathrm{I}}{6}a_k(k-6)\sqrt{6}}{k+1}$$

- Recursion relation that defines the terminating series solution of the ODE for $r = 0$

$$\left[y(u) = \sum_{k=0}^{5} a_k u^k, a_{k+1} = \frac{-\frac{\mathrm{I}}{6}a_k(k-6)\sqrt{6}}{k+1}\right]$$

- Revert the change of variables $u = x + 1 + \frac{\mathrm{I}\sqrt{6}}{2}$

$$\left[y(x) = \sum_{k=0}^{5} a_k \left(x + 1 + \frac{\mathrm{I}\sqrt{6}}{2}\right)^k, a_{k+1} = \frac{-\frac{\mathrm{I}}{6}a_k(k-6)\sqrt{6}}{k+1}\right]$$

- Recursion relation for $r = 6$

$$a_{k+1} = \frac{-\frac{\mathrm{I}}{6}a_k k\sqrt{6}}{k+7}$$

- Solution for $r = 6$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+6}, a_{k+1} = \frac{-\frac{\mathrm{I}}{6}a_k k\sqrt{6}}{k+7}\right]$$

- Revert the change of variables $u = x + 1 + \frac{\mathrm{I}\sqrt{6}}{2}$

$$\left[y(x) = \sum_{k=0}^{\infty} a_k \left(x + 1 + \frac{\mathrm{I}\sqrt{6}}{2}\right)^{k+6}, a_{k+1} = \frac{-\frac{\mathrm{I}}{6}a_k k\sqrt{6}}{k+7}\right]$$

- Combine solutions and rename parameters

$$\left[y(x) = \left(\sum_{k=0}^{5} a_k \left(x + 1 + \frac{\mathrm{I}\sqrt{6}}{2}\right)^k\right) + \left(\sum_{k=0}^{\infty} b_k \left(x + 1 + \frac{\mathrm{I}\sqrt{6}}{2}\right)^{k+6}\right), a_{k+1} = \frac{-\frac{\mathrm{I}}{6}a_k(k-6)\sqrt{6}}{k+1}, b_{k+1} = \frac{-\frac{\mathrm{I}}{6}b_k k\sqrt{6}}{k+7}\right.$$

Solve

$$\left(x^3+1\right)y''+7x^2y'+9xy=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.415 (sec)

Writing the ode as

$$\left(x^3+1\right)y''+7x^2y'+9xy=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^3+1 \\ B &= 7x^2 \\ C &= 9x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{-x(x^3+8)}{4\left(x^3+1\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -x\left(x^3+8\right) \\ t &= 4\left(x^3+1\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(-\frac{x(x^3+8)}{4\left(x^3+1\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.113: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 4 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^3+1)^2$. There is a pole at $x = -1$ of order 2. There is a pole at $x = \frac{1}{2} - \frac{i\sqrt{3}}{2}$ of order 2. There is a pole at $x = \frac{1}{2} + \frac{i\sqrt{3}}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$\begin{aligned} r = {} & \frac{7}{36\left(x - \frac{1}{2} - \frac{i\sqrt{3}}{2}\right)^2} + \frac{7}{36\left(x - \frac{1}{2} + \frac{i\sqrt{3}}{2}\right)^2} + \frac{-\frac{5}{36} + \frac{5i\sqrt{3}}{36}}{x - \frac{1}{2} - \frac{i\sqrt{3}}{2}} \\ & + \frac{-\frac{5}{36} - \frac{5i\sqrt{3}}{36}}{x - \frac{1}{2} + \frac{i\sqrt{3}}{2}} + \frac{5}{18(x+1)} + \frac{7}{36(x+1)^2} \end{aligned}$$

For the pole at $x = -1$ let b be the coefficient of $\frac{1}{(x+1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{7}{36}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{6} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{6} \end{aligned}$$

For the pole at $x = \frac{1}{2} - \frac{i\sqrt{3}}{2}$ let b be the coefficient of $\frac{1}{\left(x-\frac{1}{2}+\frac{i\sqrt{3}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{7}{36}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{6} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{6}
\end{aligned}
$$

For the pole at $x = \frac{1}{2} + \frac{i\sqrt{3}}{2}$ let b be the coefficient of $\frac{1}{\left(x-\frac{1}{2}-\frac{i\sqrt{3}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{7}{36}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{6} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{6}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = -\frac{x(x^3+8)}{4\,(x^3+1)^2}
$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{1}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = -\frac{x(x^3+8)}{4\,(x^3+1)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
-1	2	0	$\frac{7}{6}$	$-\frac{1}{6}$
$\frac{1}{2} - \frac{i\sqrt{3}}{2}$	2	0	$\frac{7}{6}$	$-\frac{1}{6}$
$\frac{1}{2} + \frac{i\sqrt{3}}{2}$	2	0	$\frac{7}{6}$	$-\frac{1}{6}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^- + \alpha_{c_3}^-\right) \\
&= \frac{1}{2} - \left(-\frac{1}{2}\right) \\
&= 1
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2} \right) + \left((-)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^-}{x-c_3} \right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{1}{6\,(x+1)} - \frac{1}{6\left(x-\frac{1}{2}+\frac{i\sqrt{3}}{2}\right)} - \frac{1}{6\left(x-\frac{1}{2}-\frac{i\sqrt{3}}{2}\right)} + (-)\,(0) \\
&= -\frac{1}{6\,(x+1)} - \frac{1}{6\left(x-\frac{1}{2}+\frac{i\sqrt{3}}{2}\right)} - \frac{1}{6\left(x-\frac{1}{2}-\frac{i\sqrt{3}}{2}\right)} \\
&= -\frac{x^2}{2x^3+2}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{6\,(x+1)} - \frac{1}{6\left(x-\frac{1}{2}+\frac{i\sqrt{3}}{2}\right)} - \frac{1}{6\left(x-\frac{1}{2}-\frac{i\sqrt{3}}{2}\right)} \right)(1) + \left(\left(\frac{1}{6\,(x+1)^2} + \frac{1}{6\left(x-\frac{1}{2}+\frac{i\sqrt{3}}{2}\right)^2} + \right.\right.$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega\,dx} \\
&= (x)\,\mathrm{e}^{\int \left(-\frac{1}{6(x+1)} - \frac{1}{6\left(x-\frac{1}{2}+\frac{i\sqrt{3}}{2}\right)} - \frac{1}{6\left(x-\frac{1}{2}-\frac{i\sqrt{3}}{2}\right)} \right) dx} \\
&= (x)\,\frac{1}{\left((x+1)\left(2x-1+i\sqrt{3}\right)\left(i\sqrt{3}-2x+1\right)\right)^{1/6}} \\
&= \frac{x}{\left((x+1)\left(2x-1+i\sqrt{3}\right)\left(i\sqrt{3}-2x+1\right)\right)^{1/6}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{7x^2}{x^3+1}\,dx} \\
&= z_1 e^{-\frac{7\ln\left(x^3+1\right)}{6}} \\
&= z_1 \left(\frac{1}{\left(x^3+1\right)^{7/6}} \right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{x}{(x^3+1)^{7/6}(-4x^3-4)^{1/6}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{7x^2}{x^3+1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{-\frac{7\ln(x^3+1)}{3}}}{(y_1)^2}\,dx \\ &= y_1 \left(\int \frac{(-4x^3-4)^{1/3}}{x^2}dx\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\frac{x}{(x^3+1)^{7/6}(-4x^3-4)^{1/6}}\right) + c_2\left(\frac{x}{(x^3+1)^{7/6}(-4x^3-4)^{1/6}}\left(\int \frac{(-4x^3-4)^{1/3}}{x^2}dx\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$(x^3+1)\left(\frac{d^2}{dx^2}y(x)\right) + 7x^2\left(\frac{d}{dx}y(x)\right) + 9xy(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{9xy(x)}{x^3+1} - \frac{7x^2\left(\frac{d}{dx}y(x)\right)}{x^3+1}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x) + \frac{7x^2\left(\frac{d}{dx}y(x)\right)}{x^3+1} + \frac{9xy(x)}{x^3+1} = 0$

☐ Check to see if x_0 is a regular singular point

  - Define functions

    $\left[P_2(x) = \frac{7x^2}{x^3+1}, P_3(x) = \frac{9x}{x^3+1}\right]$

  - $(x+1)\cdot P_2(x)$ is analytic at $x=-1$

    $\left((x+1)\cdot P_2(x)\right)\Big|_{x=-1} = \frac{7}{3}$

  - $(x+1)^2\cdot P_3(x)$ is analytic at $x=-1$

    $\left((x+1)^2\cdot P_3(x)\right)\Big|_{x=-1} = 0$

  - $x=-1$is a regular singular point

    Check to see if x_0 is a regular singular point

    $x_0 = -1$

- Multiply by denominators

  $(x^3+1)\left(\frac{d^2}{dx^2}y(x)\right)+7x^2\left(\frac{d}{dx}y(x)\right)+9xy(x)=0$
- Change variables using $x=u-1$ so that the regular singular point is at $u=0$

  $(u^3-3u^2+3u)\left(\frac{d^2}{du^2}y(u)\right)+(7u^2-14u+7)\left(\frac{d}{du}y(u)\right)+(9u-9)\,y(u)=0$
- Assume series solution for $y(u)$

  $y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

□ Rewrite ODE with series expansions

- ○ Convert $u^m\cdot y(u)$ to series expansion for $m=0..1$

  $u^m\cdot y(u)=\sum_{k=0}^{\infty}a_k u^{k+r+m}$
- ○ Shift index using $k->k-m$

  $u^m\cdot y(u)=\sum_{k=m}^{\infty}a_{k-m}u^{k+r}$
- ○ Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..2$

  $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,u^{k+r-1+m}$
- ○ Shift index using $k->k+1-m$

  $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,u^{k+r}$
- ○ Convert $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m=1..3$

  $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,u^{k+r-2+m}$
- ○ Shift index using $k->k+2-m$

  $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=-2+m}^{\infty}a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,u^{k+r}$

Rewrite ODE with series expansions

$a_0r(4+3r)\,u^{-1+r}+\left(a_1(1+r)\,(7+3r)-a_0(3r^2+11r+9)\right)u^r+\left(\sum_{k=1}^{\infty}\left(a_{k+1}(k+1+r)\,(3k+7\right.\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r(4+3r)=0$
- Values of r that satisfy the indicial equation

  $r\in\left\{0,-\frac{4}{3}\right\}$
- Each term must be 0

  $a_1(1+r)\,(7+3r)-a_0(3r^2+11r+9)=0$
- Each term in the series must be 0, giving the recursion relation

  $a_{k+1}(k+1+r)\,(3k+7+3r)-a_k(3k^2+6kr+3r^2+11k+11r+9)+a_{k-1}(k+2+r)^2=0$
- Shift index using $k->k+1$

  $a_{k+2}(k+2+r)\,(3k+10+3r)-a_{k+1}\left(3(k+1)^2+6(k+1)\,r+3r^2+11k+20+11r\right)+a_k(k+$
- Recursion relation that defines series solution to ODE

  $a_{k+2}=-\frac{k^2a_k-3k^2a_{k+1}+2kra_k-6kra_{k+1}+r^2a_k-3r^2a_{k+1}+6ka_k-17ka_{k+1}+6ra_k-17ra_{k+1}+9a_k-23a_{k+1}}{(k+2+r)(3k+10+3r)}$
- Recursion relation for $r=0$

  $a_{k+2}=-\frac{k^2a_k-3k^2a_{k+1}+6ka_k-17ka_{k+1}+9a_k-23a_{k+1}}{(k+2)(3k+10)}$
- Solution for $r=0$

  $\left[y(u)=\sum_{k=0}^{\infty}a_k u^k,a_{k+2}=-\frac{k^2a_k-3k^2a_{k+1}+6ka_k-17ka_{k+1}+9a_k-23a_{k+1}}{(k+2)(3k+10)},7a_1-9a_0=0\right]$
- Revert the change of variables $u=x+1$

$$\left[y(x)=\sum_{k=0}^{\infty} a_k(x+1)^k, a_{k+2}=-\frac{k^2 a_k-3k^2 a_{k+1}+6k a_k-17k a_{k+1}+9a_k-23a_{k+1}}{(k+2)(3k+10)}, 7a_1-9a_0=0\right]$$

- Recursion relation for $r=-\frac{4}{3}$

$$a_{k+2}=-\frac{k^2 a_k-3k^2 a_{k+1}+\frac{10}{3}k a_k-9k a_{k+1}+\frac{25}{9}a_k-\frac{17}{3}a_{k+1}}{\left(k+\frac{2}{3}\right)(3k+6)}$$

- Solution for $r=-\frac{4}{3}$

$$\left[y(u)=\sum_{k=0}^{\infty} a_k u^{k-\frac{4}{3}}, a_{k+2}=-\frac{k^2 a_k-3k^2 a_{k+1}+\frac{10}{3}k a_k-9k a_{k+1}+\frac{25}{9}a_k-\frac{17}{3}a_{k+1}}{\left(k+\frac{2}{3}\right)(3k+6)}, -a_1+\frac{a_0}{3}=0\right]$$

- Revert the change of variables $u=x+1$

$$\left[y(x)=\sum_{k=0}^{\infty} a_k(x+1)^{k-\frac{4}{3}}, a_{k+2}=-\frac{k^2 a_k-3k^2 a_{k+1}+\frac{10}{3}k a_k-9k a_{k+1}+\frac{25}{9}a_k-\frac{17}{3}a_{k+1}}{\left(k+\frac{2}{3}\right)(3k+6)}, -a_1+\frac{a_0}{3}=0\right]$$

- Combine solutions and rename parameters

$$\left[y(x)=\left(\sum_{k=0}^{\infty} a_k(x+1)^k\right)+\left(\sum_{k=0}^{\infty} b_k(x+1)^{k-\frac{4}{3}}\right), a_{k+2}=-\frac{k^2 a_k-3k^2 a_{k+1}+6k a_k-17k a_{k+1}+9a_k-23a_{k+1}}{(k+2)(3k+10)}, 7a_1\right.$$

2.1.64 Problem 66

Internal problem ID [9236]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 66
Date solved : `Monday, January 27, 2025 at 05:52:25 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$\left(2x^{5}+1\right) y''+14x^{4}y'+10x^{3}y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 1.110 (sec)

Writing the ode as

$$\left(2x^{5}+1\right) y''+14x^{4}y'+10x^{3}y = 0 \tag{1}$$
$$Ay''+By'+Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2x^{5}+1 \\ B &= 14x^{4} \\ C &= 10x^{3} \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^{2} - 4AC}{4A^{2}} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{3x^{3}(5x^{5}+6)}{\left(2x^{5}+1\right)^{2}} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 3x^{3}\left(5x^{5}+6\right) \\ t &= \left(2x^{5}+1\right)^{2} \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{3x^{3}(5x^{5}+6)}{\left(2x^{5}+1\right)^{2}}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.115: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 10 - 8 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (2x^5+1)^2$. There is a pole at $x = \frac{2^{4/5}\sqrt{5}}{8} + \frac{2^{4/5}}{8} + \frac{i2^{3/10}\sqrt{5-\sqrt{5}}}{4}$ of order 2. There is a pole at $x = \frac{2^{4/5}}{8} - \frac{2^{4/5}\sqrt{5}}{8} + \frac{i2^{3/10}\sqrt{5-\sqrt{5}}}{8} + \frac{i2^{3/10}\sqrt{5-\sqrt{5}}\,\sqrt{5}}{8}$ of order 2. There is a pole at $x = -\frac{2^{4/5}}{2}$ of order 2. There is a pole at $x = \frac{2^{4/5}}{8} - \frac{2^{4/5}\sqrt{5}}{8} - \frac{i2^{3/10}\sqrt{5-\sqrt{5}}\,\sqrt{5}}{8} - \frac{i2^{3/10}\sqrt{5-\sqrt{5}}}{8}$ of order 2. There is a pole at $x = \frac{2^{4/5}\sqrt{5}}{8} + \frac{2^{4/5}}{8} - \frac{i2^{3/10}\sqrt{5-\sqrt{5}}}{4}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \text{Expression too large to display}$$

For the pole at $x = \frac{2^{4/5}\sqrt{5}}{8} + \frac{2^{4/5}}{8} + \frac{i2^{3/10}\sqrt{5-\sqrt{5}}}{4}$ let b be the coefficient of $\frac{1}{\left(x - \frac{2^{4/5}\sqrt{5}}{8} - \frac{2^{4/5}}{8} - \frac{i2^{3/10}\sqrt{5-\sqrt{5}}}{4}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{21}{100}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{10} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{3}{10} \end{aligned}$$

For the pole at $x = \frac{2^{4/5}}{8} - \frac{2^{4/5}\sqrt{5}}{8} + \frac{i2^{3/10}\sqrt{5-\sqrt{5}}}{8} + \frac{i2^{3/10}\sqrt{5-\sqrt{5}}\,\sqrt{5}}{8}$ let b be the coefficient of $\frac{1}{\left(x-\frac{2^{4/5}}{8}+\frac{2^{4/5}\sqrt{5}}{8}-\frac{i2^{3/10}\sqrt{5-\sqrt{5}}}{8}-\frac{i2^{3/10}\sqrt{5-\sqrt{5}}\,\sqrt{5}}{8}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{21}{100}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0\\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{10}\\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{3}{10}
\end{aligned}
$$

For the pole at $x = -\frac{2^{4/5}}{2}$ let b be the coefficient of $\frac{1}{\left(x+\frac{2^{4/5}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{21}{100}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0\\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{10}\\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{3}{10}
\end{aligned}
$$

For the pole at $x = \frac{2^{4/5}}{8} - \frac{2^{4/5}\sqrt{5}}{8} - \frac{i2^{3/10}\sqrt{5-\sqrt{5}}\,\sqrt{5}}{8} - \frac{i2^{3/10}\sqrt{5-\sqrt{5}}}{8}$ let b be the coefficient of $\frac{1}{\left(x-\frac{2^{4/5}}{8}+\frac{2^{4/5}\sqrt{5}}{8}+\frac{i2^{3/10}\sqrt{5-\sqrt{5}}\,\sqrt{5}}{8}+\frac{i2^{3/10}\sqrt{5-\sqrt{5}}}{8}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{21}{100}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0\\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{10}\\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{3}{10}
\end{aligned}
$$

For the pole at $x = \frac{2^{4/5}\sqrt{5}}{8} + \frac{2^{4/5}}{8} - \frac{i2^{3/10}\sqrt{5-\sqrt{5}}}{4}$ let b be the coefficient of $\frac{1}{\left(x-\frac{2^{4/5}\sqrt{5}}{8}-\frac{2^{4/5}}{8}+\frac{i2^{3/10}\sqrt{5-\sqrt{5}}}{4}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{21}{100}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0\\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{10}\\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{3}{10}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = \frac{3x^3(5x^5+6)}{(2x^5+1)^2}
$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{15}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0\\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{2}\\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{3x^3(5x^5+6)}{(2x^5+1)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
$\frac{2^{4/5}\sqrt{5}}{8}+\frac{2^{4/5}}{8}+\frac{i2^{3/10}\sqrt{5-\sqrt{5}}}{4}$	2	0	$\frac{7}{10}$	$\frac{3}{10}$
$\frac{2^{4/5}}{8}-\frac{2^{4/5}\sqrt{5}}{8}+\frac{i2^{3/10}\sqrt{5-\sqrt{5}}}{8}+\frac{i2^{3/10}\sqrt{5-\sqrt{5}}\,\sqrt{5}}{8}$	2	0	$\frac{7}{10}$	$\frac{3}{10}$
$-\frac{2^{4/5}}{2}$	2	0	$\frac{7}{10}$	$\frac{3}{10}$
$\frac{2^{4/5}}{8}-\frac{2^{4/5}\sqrt{5}}{8}-\frac{i2^{3/10}\sqrt{5-\sqrt{5}}\,\sqrt{5}}{8}-\frac{i2^{3/10}\sqrt{5-\sqrt{5}}}{8}$	2	0	$\frac{7}{10}$	$\frac{3}{10}$
$\frac{2^{4/5}\sqrt{5}}{8}+\frac{2^{4/5}}{8}-\frac{i2^{3/10}\sqrt{5-\sqrt{5}}}{4}$	2	0	$\frac{7}{10}$	$\frac{3}{10}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{5}{2}$	$-\frac{3}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+=\frac{5}{2}$ then

$$\begin{aligned}d&=\alpha_\infty^+-\left(\alpha_{c_1}^-+\alpha_{c_2}^-+\alpha_{c_3}^-+\alpha_{c_4}^-+\alpha_{c_5}^-\right)\\&=\frac{5}{2}-\left(\frac{3}{2}\right)\\&=1\end{aligned}$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$\omega=\sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c+\frac{\alpha_c^{s(c)}}{x-c}\right)+s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}\omega&=\left((-)[\sqrt{r}]_{c_1}+\frac{\alpha_{c_1}^-}{x-c_1}\right)+\left((-)[\sqrt{r}]_{c_2}+\frac{\alpha_{c_2}^-}{x-c_2}\right)+\left((-)[\sqrt{r}]_{c_3}+\frac{\alpha_{c_3}^-}{x-c_3}\right)+\left((-)[\sqrt{r}]_{c_4}+\frac{\alpha_{c_4}^-}{x-c_4}\right)\\&=\frac{3}{10\left(x-\frac{2^{4/5}\sqrt{5}}{8}-\frac{2^{4/5}}{8}-\frac{i2^{3/10}\sqrt{5-\sqrt{5}}}{4}\right)}+\frac{3}{10\left(x-\frac{2^{4/5}}{8}+\frac{2^{4/5}\sqrt{5}}{8}-\frac{i2^{3/10}\sqrt{5-\sqrt{5}}}{8}-\frac{i2^{3/10}\sqrt{5-\sqrt{5}}\,\sqrt{5}}{8}\right)}+\frac{}{10(}\\&=\frac{3}{10\left(x-\frac{2^{4/5}\sqrt{5}}{8}-\frac{2^{4/5}}{8}-\frac{i2^{3/10}\sqrt{5-\sqrt{5}}}{4}\right)}+\frac{3}{10\left(x-\frac{2^{4/5}}{8}+\frac{2^{4/5}\sqrt{5}}{8}-\frac{i2^{3/10}\sqrt{5-\sqrt{5}}}{8}-\frac{i2^{3/10}\sqrt{5-\sqrt{5}}\,\sqrt{5}}{8}\right)}+\frac{}{10(}\\&=\frac{3x^4}{2x^5+1}\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p''+2\omega p'+\left(\omega'+\omega^2-r\right)p=0 \tag{1A}$$

Let

$$p(x)=x+a_0 \tag{2A}$$

Substituting the above in eq. (1A) and Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0=0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x$$

Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= (x)\, \mathrm{e}^{\int \left(\frac{3}{10\left(x - \frac{2^{4/5}\sqrt{5}}{8} - \frac{2^{4/5}}{8} - \frac{i 2^{3/10}\sqrt{5-\sqrt{5}}}{4}\right)} + \frac{3}{10\left(x - \frac{2^{4/5}}{8} + \frac{2^{4/5}\sqrt{5}}{8} - \frac{i 2^{3/10}\sqrt{5-\sqrt{5}}}{8} - \frac{i 2^{3/10}\sqrt{5-\sqrt{5}}\,\sqrt{5}}{8}\right)} + \frac{3}{10\left(x + \frac{2^{4/5}}{2}\right)} + \frac{}{10\left(x - \frac{2^{4/5}}{8} + 2^{4/}\right.} \right.} \\
&= (x) \left(\left(2^{4/5} + 2x\right) \left(2^{4/5}\sqrt{5} + 2i 2^{3/10}\sqrt{5 - \sqrt{5}} + 2^{4/5} - 8x\right) \left(8x - 2^{4/5}\sqrt{5} - 2^{4/5} + 2i 2^{3/10}\sqrt{5 - \sqrt{5}}\right.\right. \\
&= x 8^{3/10} \left(\left(x + \frac{2^{4/5}}{2}\right) \left(i 2^{3/10}\sqrt{5 - \sqrt{5}} + \frac{\left(-\sqrt{5} - 1\right) 2^{4/5}}{2} + 4x\right) \left(i\left(\sqrt{5} + 1\right) 2^{3/10}\sqrt{5 - \sqrt{5}} + \left(-\sqrt{\right.\right.\right.
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{14x^4}{2x^5+1}\, dx} \\
&= z_1 e^{-\frac{7\ln\left(2x^5+1\right)}{10}} \\
&= z_1 \left(\frac{1}{\left(2x^5+1\right)^{7/10}}\right)
\end{aligned}
$$

Which simplifies to

$$y_1 = \frac{x 8^{3/10} \left(1024x^5 + 512\right)^{3/10}}{\left(2x^5 + 1\right)^{7/10}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{14x^4}{2x^5+1}\, dx}}{\left(y_1\right)^2}\, dx \\
&= y_1 \int \frac{e^{-\frac{7\ln\left(2x^5+1\right)}{5}}}{\left(y_1\right)^2}\, dx \\
&= y_1 \left(\int \frac{8^{2/5}}{8x^2 \left(1024x^5 + 512\right)^{3/5}} dx\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{x 8^{3/10} \left(1024x^5 + 512\right)^{3/10}}{\left(2x^5 + 1\right)^{7/10}}\right) + c_2 \left(\frac{x 8^{3/10} \left(1024x^5 + 512\right)^{3/10}}{\left(2x^5 + 1\right)^{7/10}} \left(\int \frac{8^{2/5}}{8x^2 \left(1024x^5 + 512\right)^{3/5}} dx\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

2.1.65 Problem 67

Internal problem ID [9237]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 67
Date solved : Monday, January 27, 2025 at 05:52:27 PM
CAS classification : [[_2nd_order, _with_linear_symmetries]]

Solve

$$y'' + x^6 y' + 7x^5 y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.413 (sec)

Writing the ode as

$$y'' + x^6 y' + 7x^5 y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= x^6 \\ C &= 7x^5 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^5(x^7 - 16)}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^5\left(x^7 - 16\right) \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^5(x^7 - 16)}{4}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.116: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 12 \\ &= -12 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -12 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -12$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{12}{2} = 6$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{6} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^6$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x^6}{2} - \frac{4}{x} - \frac{16}{x^8} - \frac{128}{x^{15}} - \frac{1280}{x^{22}} - \frac{14336}{x^{29}} - \frac{172032}{x^{36}} - \frac{2162688}{x^{43}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 6$ gives

$$[\sqrt{r}]_\infty = \sum_{i=0}^{6} a_i x^i = \frac{x^6}{2} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^5 = x^5$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{x^{12}}{4}$$

This shows that the coefficient of x^5 in the above is 0. Now we need to find the coefficient of x^5 in r. How this is done depends on if $v = 0$ or not. Since $v = 6$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of x^5 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^5(x^7 - 16)}{4} \\ &= Q + \frac{R}{4} \\ &= \left(\frac{1}{4}x^{12} - 4x^5\right) + (0) \\ &= \frac{1}{4}x^{12} - 4x^5 \end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is -4. Now b can be found.

$$\begin{aligned} b &= (-4) - (0) \\ &= -4 \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{x^6}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-4}{\frac{1}{2}} - 6\right) &= -7 \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-4}{\frac{1}{2}} - 6\right) &= 1 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^5(x^7 - 16)}{4}$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-12	$\frac{x^6}{2}$	-7	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$, and since there are no poles then

$$
\begin{aligned}
d &= \alpha_\infty^- \\
&= 1
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= (-)[\sqrt{r}]_\infty \\
&= 0 + (-)\left(\frac{x^6}{2}\right) \\
&= -\frac{x^6}{2} \\
&= -\frac{x^6}{2}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = x + a_0 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(0) + 2\left(-\frac{x^6}{2}\right)(1) + \left((-3x^5) + \left(-\frac{x^6}{2}\right)^2 - \left(\frac{x^5(x^7-16)}{4}\right)\right) = 0
$$

$$
x^5 a_0 = 0
$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$
\{a_0 = 0\}
$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$
p(x) = x
$$

Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= pe^{\int \omega\, dx} \\
&= (x)\,\mathrm{e}^{\int -\frac{x^6}{2} dx} \\
&= (x)\,\mathrm{e}^{-\frac{x^7}{14}} \\
&= x\,\mathrm{e}^{-\frac{x^7}{14}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{x^6}{1} dx} \\
&= z_1 e^{-\frac{x^7}{14}} \\
&= z_1\left(\mathrm{e}^{-\frac{x^7}{14}}\right)
\end{aligned}
$$

Which simplifies to

$$y_1 = \mathrm{e}^{-\frac{x^7}{7}} x$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x^6}{1}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-\frac{x^7}{7}}}{(y_1)^2}\, dx \\
&= y_1 \left(\frac{7^{6/7}(-1)^{1/7}\left(-\frac{7x^6(-1)^{6/7}\Gamma\left(\frac{6}{7}\right)}{(-x^7)^{6/7}} + \frac{7\,7^{1/7}(-1)^{6/7}\mathrm{e}^{\frac{x^7}{7}}}{x} + \frac{7x^6(-1)^{6/7}\Gamma\left(\frac{6}{7}, -\frac{x^7}{7}\right)}{(-x^7)^{6/7}}\right)}{49} \right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-\frac{x^7}{7}} x\right) \\
&\quad + c_2 \left(\mathrm{e}^{-\frac{x^7}{7}} x \left(\frac{7^{6/7}(-1)^{1/7}\left(-\frac{7x^6(-1)^{6/7}\Gamma\left(\frac{6}{7}\right)}{(-x^7)^{6/7}} + \frac{7\,7^{1/7}(-1)^{6/7}\mathrm{e}^{\frac{x^7}{7}}}{x} + \frac{7x^6(-1)^{6/7}\Gamma\left(\frac{6}{7}, -\frac{x^7}{7}\right)}{(-x^7)^{6/7}}\right)}{49} \right) \right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve
$\frac{d^2}{dx^2} y(x) + x^6 \left(\frac{d}{dx} y(x)\right) + 7x^5 y(x) = 0$

- Highest derivative means the order of the ODE is 2
  $\frac{d^2}{dx^2} y(x)$
- Assume series solution for $y(x)$
  $y(x) = \sum_{k=0}^{\infty} a_k x^k$

☐ Rewrite ODE with series expansions

- ◦ Convert $x^5 \cdot y(x)$ to series expansion
  $x^5 \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+5}$
- ◦ Shift index using $k- >k-5$
  $x^5 \cdot y(x) = \sum_{k=5}^{\infty} a_{k-5} x^k$
- ◦ Convert $x^6 \cdot \left(\frac{d}{dx} y(x)\right)$ to series expansion
  $x^6 \cdot \left(\frac{d}{dx} y(x)\right) = \sum_{k=0}^{\infty} a_k k\, x^{k+5}$

- Shift index using $k->k-5$

  $x^6 \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=5}^{\infty} a_{k-5}(k-5)\, x^k$

- Convert $\frac{d^2}{dx^2}y(x)$ to series expansion

  $\frac{d^2}{dx^2}y(x) = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$

- Shift index using $k->k+2$

  $\frac{d^2}{dx^2}y(x) = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$

  Rewrite ODE with series expansions

  $30a_6x^4 + 20a_5x^3 + 12a_4x^2 + 6a_3x + 2a_2 + \left(\sum_{k=5}^{\infty} (a_{k+2}(k+2)\,(k+1) + a_{k-5}(k+2))\, x^k\right) = 0$

- The coefficients of each power of x must be 0

  $[2a_2 = 0, 6a_3 = 0, 12a_4 = 0, 20a_5 = 0, 30a_6 = 0]$

- Solve for the dependent coefficient(s)

  $\{a_2 = 0, a_3 = 0, a_4 = 0, a_5 = 0, a_6 = 0\}$

- Each term in the series must be 0, giving the recursion relation

  $(k+2)\,(ka_{k+2} + a_{k-5} + a_{k+2}) = 0$

- Shift index using $k->k+5$

  $(k+7)\,((k+5)\, a_{k+7} + a_k + a_{k+7}) = 0$

- Recursion relation that defines the series solution to the ODE

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^k, a_{k+7} = -\frac{a_k}{k+6}, a_2 = 0, a_3 = 0, a_4 = 0, a_5 = 0, a_6 = 0\right]$

CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$\left(x^8+1\right) y''-16x^7y'+72x^6y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 459.996 (sec)

Writing the ode as

$$\left(x^8+1\right) y''-16x^7y'+72x^6y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^8+1 \\ B &= -16x^7 \\ C &= 72x^6 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=y e^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r=\frac{-128x^6}{\left(x^8+1\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -128x^6 \\ t &= \left(x^8+1\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(-\frac{128x^6}{\left(x^8+1\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.118: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 16 - 6 \\ &= 10 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (x^8+1)^2$. There is a pole at $x = \frac{\sqrt{2}\,\sqrt{2-\sqrt{2}}}{2} + \frac{\sqrt{2-\sqrt{2}}}{2} + \frac{i\sqrt{2-\sqrt{2}}}{2}$ of order 2. There is a pole at $x = \frac{\sqrt{2-\sqrt{2}}}{2} + \frac{i\sqrt{2-\sqrt{2}}\,\sqrt{2}}{2} + \frac{i\sqrt{2-\sqrt{2}}}{2}$ of order 2. There is a pole at $x = -\frac{\sqrt{2-\sqrt{2}}}{2} + \frac{i\sqrt{2-\sqrt{2}}\,\sqrt{2}}{2} + \frac{i\sqrt{2-\sqrt{2}}}{2}$ of order 2. There is a pole at $x = -\frac{\sqrt{2}\,\sqrt{2-\sqrt{2}}}{2} - \frac{\sqrt{2-\sqrt{2}}}{2} + \frac{i\sqrt{2-\sqrt{2}}}{2}$ of order 2. There is a pole at $x = -\frac{\sqrt{2}\,\sqrt{2-\sqrt{2}}}{2} - \frac{\sqrt{2-\sqrt{2}}}{2} - \frac{i\sqrt{2-\sqrt{2}}}{2}$ of order 2. There is a pole at $x = -\frac{\sqrt{2-\sqrt{2}}}{2} - \frac{i\sqrt{2-\sqrt{2}}\,\sqrt{2}}{2} - \frac{i\sqrt{2-\sqrt{2}}}{2}$ of order 2. There is a pole at $x = \frac{\sqrt{2-\sqrt{2}}}{2} - \frac{i\sqrt{2-\sqrt{2}}\,\sqrt{2}}{2} - \frac{i\sqrt{2-\sqrt{2}}}{2}$ of order 2. There is a pole at $x = \frac{\sqrt{2}\,\sqrt{2-\sqrt{2}}}{2} + \frac{\sqrt{2-\sqrt{2}}}{2} - \frac{i\sqrt{2-\sqrt{2}}}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 10 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 10 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$
\begin{aligned}
r = {} & \frac{2}{\left(x-\frac{\sqrt{2+\sqrt{2}}}{2}-\frac{i\sqrt{2-\sqrt{2}}}{2}\right)^{2}}+\frac{2}{\left(x-\frac{\sqrt{2-\sqrt{2}}}{2}-\frac{i\sqrt{2+\sqrt{2}}}{2}\right)^{2}}+\frac{2}{\left(x+\frac{\sqrt{2-\sqrt{2}}}{2}-\frac{i\sqrt{2+\sqrt{2}}}{2}\right)^{2}} \\
& +\frac{2}{\left(x+\frac{\sqrt{2+\sqrt{2}}}{2}-\frac{i\sqrt{2-\sqrt{2}}}{2}\right)^{2}}+\frac{2}{\left(x+\frac{\sqrt{2+\sqrt{2}}}{2}+\frac{i\sqrt{2-\sqrt{2}}}{2}\right)^{2}} \\
& +\frac{2}{\left(x+\frac{\sqrt{2-\sqrt{2}}}{2}+\frac{i\sqrt{2+\sqrt{2}}}{2}\right)^{2}}+\frac{2}{\left(x-\frac{\sqrt{2-\sqrt{2}}}{2}+\frac{i\sqrt{2+\sqrt{2}}}{2}\right)^{2}} \\
& +\frac{2}{\left(x-\frac{\sqrt{2+\sqrt{2}}}{2}+\frac{i\sqrt{2-\sqrt{2}}}{2}\right)^{2}}+\frac{2\left(\frac{\sqrt{2+\sqrt{2}}}{2}+\frac{i\sqrt{2-\sqrt{2}}}{2}\right)^{7}}{x-\frac{\sqrt{2+\sqrt{2}}}{2}-\frac{i\sqrt{2-\sqrt{2}}}{2}}+\frac{2\left(\frac{\sqrt{2-\sqrt{2}}}{2}+\frac{i\sqrt{2+\sqrt{2}}}{2}\right)^{7}}{x-\frac{\sqrt{2-\sqrt{2}}}{2}-\frac{i\sqrt{2+\sqrt{2}}}{2}} \\
& +\frac{2\left(-\frac{\sqrt{2-\sqrt{2}}}{2}+\frac{i\sqrt{2+\sqrt{2}}}{2}\right)^{7}}{x+\frac{\sqrt{2-\sqrt{2}}}{2}-\frac{i\sqrt{2+\sqrt{2}}}{2}}+\frac{2\left(-\frac{\sqrt{2+\sqrt{2}}}{2}+\frac{i\sqrt{2-\sqrt{2}}}{2}\right)^{7}}{x+\frac{\sqrt{2+\sqrt{2}}}{2}-\frac{i\sqrt{2-\sqrt{2}}}{2}}+\frac{2\left(-\frac{\sqrt{2+\sqrt{2}}}{2}-\frac{i\sqrt{2-\sqrt{2}}}{2}\right)^{7}}{x+\frac{\sqrt{2+\sqrt{2}}}{2}+\frac{i\sqrt{2-\sqrt{2}}}{2}} \\
& +\frac{2\left(-\frac{\sqrt{2-\sqrt{2}}}{2}-\frac{i\sqrt{2+\sqrt{2}}}{2}\right)^{7}}{x+\frac{\sqrt{2-\sqrt{2}}}{2}+\frac{i\sqrt{2+\sqrt{2}}}{2}}+\frac{2\left(\frac{\sqrt{2-\sqrt{2}}}{2}-\frac{i\sqrt{2+\sqrt{2}}}{2}\right)^{7}}{x-\frac{\sqrt{2-\sqrt{2}}}{2}+\frac{i\sqrt{2+\sqrt{2}}}{2}}+\frac{2\left(\frac{\sqrt{2+\sqrt{2}}}{2}-\frac{i\sqrt{2-\sqrt{2}}}{2}\right)^{7}}{x-\frac{\sqrt{2+\sqrt{2}}}{2}+\frac{i\sqrt{2-\sqrt{2}}}{2}}
\end{aligned}
$$

For the pole at $x=\frac{\sqrt{2}\,\sqrt{2-\sqrt{2}}}{2}+\frac{\sqrt{2-\sqrt{2}}}{2}+\frac{i\sqrt{2-\sqrt{2}}}{2}$ let b be the coefficient of $\frac{1}{\left(x-\frac{\sqrt{2}\,\sqrt{2-\sqrt{2}}}{2}-\frac{\sqrt{2-\sqrt{2}}}{2}-\frac{i\sqrt{2-\sqrt{2}}}{2}\right)^{2}}$ in the partial fractions decomposition of r given above. Therefore $b=2$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^{+} &= \frac{1}{2}+\sqrt{1+4b}=2 \\
\alpha_c^{-} &= \frac{1}{2}-\sqrt{1+4b}=-1
\end{aligned}
$$

For the pole at $x=\frac{\sqrt{2-\sqrt{2}}}{2}+\frac{i\sqrt{2-\sqrt{2}}\,\sqrt{2}}{2}+\frac{i\sqrt{2-\sqrt{2}}}{2}$ let b be the coefficient of $\frac{1}{\left(x-\frac{\sqrt{2-\sqrt{2}}}{2}-\frac{i\sqrt{2-\sqrt{2}}\,\sqrt{2}}{2}-\frac{i\sqrt{2-\sqrt{2}}}{2}\right)^{2}}$ in the partial fractions decomposition of r given above. Therefore $b=2$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^{+} &= \frac{1}{2}+\sqrt{1+4b}=2 \\
\alpha_c^{-} &= \frac{1}{2}-\sqrt{1+4b}=-1
\end{aligned}
$$

For the pole at $x=-\frac{\sqrt{2-\sqrt{2}}}{2}+\frac{i\sqrt{2-\sqrt{2}}\,\sqrt{2}}{2}+\frac{i\sqrt{2-\sqrt{2}}}{2}$ let b be the coefficient of $\frac{1}{\left(x+\frac{\sqrt{2-\sqrt{2}}}{2}-\frac{i\sqrt{2-\sqrt{2}}\,\sqrt{2}}{2}-\frac{i\sqrt{2-\sqrt{2}}}{2}\right)^{2}}$ in the partial fractions decomposition of r given above. Therefore $b=2$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^{+} &= \frac{1}{2}+\sqrt{1+4b}=2 \\
\alpha_c^{-} &= \frac{1}{2}-\sqrt{1+4b}=-1
\end{aligned}
$$

For the pole at $x=-\frac{\sqrt{2}\,\sqrt{2-\sqrt{2}}}{2}-\frac{\sqrt{2-\sqrt{2}}}{2}+\frac{i\sqrt{2-\sqrt{2}}}{2}$ let b be the coefficient of $\frac{1}{\left(x+\frac{\sqrt{2}\,\sqrt{2-\sqrt{2}}}{2}+\frac{\sqrt{2-\sqrt{2}}}{2}-\frac{i\sqrt{2-\sqrt{2}}}{2}\right)^{2}}$ in the partial fractions decomposition of r given above. Therefore $b=2$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^{+} &= \frac{1}{2}+\sqrt{1+4b}=2 \\
\alpha_c^{-} &= \frac{1}{2}-\sqrt{1+4b}=-1
\end{aligned}
$$

For the pole at $x = -\frac{\sqrt{2}\,\sqrt{2-\sqrt{2}}}{2} - \frac{\sqrt{2-\sqrt{2}}}{2} - \frac{i\sqrt{2-\sqrt{2}}}{2}$ let b be the coefficient of $\frac{1}{\left(x+\frac{\sqrt{2}\,\sqrt{2-\sqrt{2}}}{2}+\frac{\sqrt{2-\sqrt{2}}}{2}+\frac{i\sqrt{2-\sqrt{2}}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1
\end{aligned}
$$

For the pole at $x = -\frac{\sqrt{2-\sqrt{2}}}{2} - \frac{i\sqrt{2-\sqrt{2}}\,\sqrt{2}}{2} - \frac{i\sqrt{2-\sqrt{2}}}{2}$ let b be the coefficient of $\frac{1}{\left(x+\frac{\sqrt{2-\sqrt{2}}}{2}+\frac{i\sqrt{2-\sqrt{2}}\,\sqrt{2}}{2}+\frac{i\sqrt{2-\sqrt{2}}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1
\end{aligned}
$$

For the pole at $x = \frac{\sqrt{2-\sqrt{2}}}{2} - \frac{i\sqrt{2-\sqrt{2}}\,\sqrt{2}}{2} - \frac{i\sqrt{2-\sqrt{2}}}{2}$ let b be the coefficient of $\frac{1}{\left(x-\frac{\sqrt{2-\sqrt{2}}}{2}+\frac{i\sqrt{2-\sqrt{2}}\,\sqrt{2}}{2}+\frac{i\sqrt{2-\sqrt{2}}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1
\end{aligned}
$$

For the pole at $x = \frac{\sqrt{2}\,\sqrt{2-\sqrt{2}}}{2} + \frac{\sqrt{2-\sqrt{2}}}{2} - \frac{i\sqrt{2-\sqrt{2}}}{2}$ let b be the coefficient of $\frac{1}{\left(x-\frac{\sqrt{2}\,\sqrt{2-\sqrt{2}}}{2}-\frac{\sqrt{2-\sqrt{2}}}{2}+\frac{i\sqrt{2-\sqrt{2}}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1
\end{aligned}
$$

Since the order of r at ∞ is $10 > 2$ then

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= 0 \\
\alpha_\infty^- &= 1
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = -\frac{128x^6}{(x^8+1)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
10	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^- + \alpha_{c_3}^- + \alpha_{c_4}^- + \alpha_{c_5}^- + \alpha_{c_6}^- + \alpha_{c_7}^- + \alpha_{c_8}^+\right) \\ &= 1 - (-5) \\ &= 6 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2}\right) + \left((-)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^-}{x-c_3}\right) + \left((-)[\sqrt{r}]_{c_4} + \frac{\alpha_{c_4}^-}{x-c_4}\right) \\ &= -\frac{1}{x - \frac{\sqrt{2}\sqrt{2-\sqrt{2}}}{2} - \frac{\sqrt{2-\sqrt{2}}}{2} - \frac{i\sqrt{2-\sqrt{2}}}{2}} - \frac{1}{x - \frac{\sqrt{2-\sqrt{2}}}{2} - \frac{i\sqrt{2-\sqrt{2}}\sqrt{2}}{2} - \frac{i\sqrt{2-\sqrt{2}}}{2}} - \frac{1}{x + \frac{\sqrt{2-\sqrt{2}}}{2} - \frac{i\sqrt{2-\sqrt{2}}\sqrt{2}}{2} -} \\ &= -\frac{1}{x - \frac{\sqrt{2}\sqrt{2-\sqrt{2}}}{2} - \frac{\sqrt{2-\sqrt{2}}}{2} - \frac{i\sqrt{2-\sqrt{2}}}{2}} - \frac{1}{x - \frac{\sqrt{2-\sqrt{2}}}{2} - \frac{i\sqrt{2-\sqrt{2}}\sqrt{2}}{2} - \frac{i\sqrt{2-\sqrt{2}}}{2}} - \frac{1}{x + \frac{\sqrt{2-\sqrt{2}}}{2} - \frac{i\sqrt{2-\sqrt{2}}\sqrt{2}}{2} -} \\ &= \frac{\left((3x^6 - 3ix^4 - 3ix^2 - 3)\sqrt{2} - 3(x^2+1)\left((-1+i)x^4 + 1 + i\right)\right)\sqrt{2-\sqrt{2}} - 3\left(\left((-1+i)x^4 + 1 + i\right)\right.}{2\left(x\sqrt{2-\sqrt{2}} + x^2 + 1\right)\left(x\left(1+\sqrt{2}\right)\sqrt{2-\sqrt{2}} + x^2 + 1\right)\left(x^2 - x\sqrt{2-\sqrt{2}} + 1\right)\left(-x\left(1+\sqrt{2}\right)\right.} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 6$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}$$

Let

$$p(x) = x^6 + x^5 a_5 + x^4 a_4 + x^3 a_3 + x^2 a_2 + x a_1 + a_0 \tag{2A}$$

Substituting the above in eq. (1A) and Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\left\{a_0 = -\frac{i\sqrt{2} - 1 + i}{i\sqrt{2} + 1 + i}, a_1 = \frac{\left(\frac{12}{7} - \frac{12i}{7}\right)\sqrt{2}}{\left(i\sqrt{2} + 1 + i\right)\sqrt{2-\sqrt{2}}}, a_2 = -\frac{15\left(-\sqrt{2} - 1 + i\right)}{7\left(i\sqrt{2} + 1 + i\right)}, a_3 = \frac{32}{7\sqrt{2-\sqrt{2}}\left(i\sqrt{2} + 1\right.}\right.$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^6 + \frac{\left(\frac{12}{7} + \frac{12i}{7}\right)x^5\sqrt{2}}{\left(i\sqrt{2} + 1 + i\right)\sqrt{2-\sqrt{2}}} + \frac{15x^4\left(\sqrt{2} + 1 + i\right)}{7\left(i\sqrt{2} + 1 + i\right)} + \frac{32x^3}{7\sqrt{2-\sqrt{2}}\left(i\sqrt{2} + 1 + i\right)} - \frac{15x^2\left(-\sqrt{2} - 1\right.}{7\left(i\sqrt{2} + 1 +\right.}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega\, dx} \\ &= \left(x^6 + \frac{\left(\frac{12}{7} + \frac{12i}{7}\right)x^5\sqrt{2}}{\left(i\sqrt{2} + 1 + i\right)\sqrt{2-\sqrt{2}}} + \frac{15x^4\left(\sqrt{2} + 1 + i\right)}{7\left(i\sqrt{2} + 1 + i\right)} + \frac{32x^3}{7\sqrt{2-\sqrt{2}}\left(i\sqrt{2} + 1 + i\right)} - \frac{15x^2\left(-\sqrt{2} -\right.}{7\left(i\sqrt{2} + 1\right.}\right. \\ &= \left(x^6 + \frac{\left(\frac{12}{7} + \frac{12i}{7}\right)x^5\sqrt{2}}{\left(i\sqrt{2} + 1 + i\right)\sqrt{2-\sqrt{2}}} + \frac{15x^4\left(\sqrt{2} + 1 + i\right)}{7\left(i\sqrt{2} + 1 + i\right)} + \frac{32x^3}{7\sqrt{2-\sqrt{2}}\left(i\sqrt{2} + 1 + i\right)} - \frac{15x^2\left(-\sqrt{2} -\right.}{7\left(i\sqrt{2} + 1\right.}\right. \\ &= \text{Expression too large to display} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-16x^7}{x^8+1}\,dx} \\ &= z_1 e^{\ln(x^8+1)} \\ &= z_1\left(x^8+1\right) \end{aligned}$$

Which simplifies to

$$y_1 = \text{Expression too large to display}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-16x^7}{x^8+1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{2\ln(x^8+1)}}{(y_1)^2}\,dx \\ &= y_1(\text{Expression too large to display}) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(\text{Expression too large to display}) \\ &\quad + c_2(\text{Expression too large to display}(\text{Expression too large to display})) \end{aligned}$$

Will add steps showing solving for IC soon.

CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$y'' + x^5 y' + 6x^4 y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.429 (sec)

Writing the ode as

$$y'' + x^5 y' + 6x^4 y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= x^5 \\ C &= 6x^4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^4(x^6 - 14)}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^4(x^6 - 14) \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^4(x^6 - 14)}{4}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.119: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 10 \\ &= -10 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -10 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -10$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{10}{2} = 5$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{5} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^5$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x^5}{2} - \frac{7}{2x} - \frac{49}{4x^7} - \frac{343}{4x^{13}} - \frac{12005}{16x^{19}} - \frac{117649}{16x^{25}} - \frac{2470629}{32x^{31}} - \frac{27176919}{32x^{37}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 5$ gives

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{5} a_i x^i \\
&= \frac{x^5}{2}
\end{aligned} \tag{10}
$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^4 = x^4$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$
\left([\sqrt{r}]_\infty\right)^2 = \frac{x^{10}}{4}
$$

This shows that the coefficient of x^4 in the above is 0. Now we need to find the coefficient of x^4 in r. How this is done depends on if $v = 0$ or not. Since $v = 5$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$
r = Q + \frac{R}{t}
$$

Where Q is the quotient and R is the remainder. Then the coefficient of x^4 in r will be the coefficient this term in the quotient. Doing long division gives

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{x^4(x^6 - 14)}{4} \\
&= Q + \frac{R}{4} \\
&= \left(\frac{1}{4}x^{10} - \frac{7}{2}x^4\right) + (0) \\
&= \frac{1}{4}x^{10} - \frac{7}{2}x^4
\end{aligned}
$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is $-\frac{7}{2}$. Now b can be found.

$$
\begin{aligned}
b &= \left(-\frac{7}{2}\right) - (0) \\
&= -\frac{7}{2}
\end{aligned}
$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \frac{x^5}{2} \\
\alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-\frac{7}{2}}{\frac{1}{2}} - 5\right) &= -6 \\
\alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-\frac{7}{2}}{\frac{1}{2}} - 5\right) &= 1
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{x^4(x^6 - 14)}{4}
$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-10	$\frac{x^5}{2}$	-6	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$, and since there are no poles then

$$\begin{aligned} d &= \alpha_\infty^- \\ &= 1 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= (-)[\sqrt{r}]_\infty \\ &= 0 + (-)\left(\frac{x^5}{2}\right) \\ &= -\frac{x^5}{2} \\ &= -\frac{x^5}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(-\frac{x^5}{2}\right)(1) + \left(\left(-\frac{5x^4}{2}\right) + \left(-\frac{x^5}{2}\right)^2 - \left(\frac{x^4(x^6-14)}{4}\right)\right) &= 0 \\ x^4 a_0 &= 0 \end{aligned}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= (x)\, \mathrm{e}^{\int -\frac{x^5}{2} dx} \\ &= (x)\, \mathrm{e}^{-\frac{x^6}{12}} \\ &= x\, \mathrm{e}^{-\frac{x^6}{12}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{x^5}{1} dx} \\ &= z_1 e^{-\frac{x^6}{12}} \\ &= z_1 \left(\mathrm{e}^{-\frac{x^6}{12}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-\frac{x^6}{6}} x$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{x^5}{1}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-\frac{x^6}{6}}}{(y_1)^2}\, dx \\ &= y_1 \left(\frac{6^{5/6}(-1)^{1/6}\left(-\frac{6x^5(-1)^{5/6}\Gamma\left(\frac{5}{6}\right)}{(-x^6)^{5/6}} + \frac{6\, 6^{1/6}(-1)^{5/6}\mathrm{e}^{\frac{x^6}{6}}}{x} + \frac{6x^5(-1)^{5/6}\Gamma\left(\frac{5}{6}, -\frac{x^6}{6}\right)}{(-x^6)^{5/6}}\right)}{36} \right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\mathrm{e}^{-\frac{x^6}{6}} x\right) \\ &\quad + c_2 \left(\mathrm{e}^{-\frac{x^6}{6}} x \left(\frac{6^{5/6}(-1)^{1/6}\left(-\frac{6x^5(-1)^{5/6}\Gamma\left(\frac{5}{6}\right)}{(-x^6)^{5/6}} + \frac{6\, 6^{1/6}(-1)^{5/6}\mathrm{e}^{\frac{x^6}{6}}}{x} + \frac{6x^5(-1)^{5/6}\Gamma\left(\frac{5}{6}, -\frac{x^6}{6}\right)}{(-x^6)^{5/6}}\right)}{36} \right) \right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$\frac{d^2}{dx^2}y(x) + x^5\left(\frac{d}{dx}y(x)\right) + 6x^4 y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^k$

- ☐ Rewrite ODE with series expansions
  - Convert $x^4 \cdot y(x)$ to series expansion

    $x^4 \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+4}$
  - Shift index using $k- > k-4$

    $x^4 \cdot y(x) = \sum_{k=4}^{\infty} a_{k-4} x^k$
  - Convert $x^5 \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion

    $x^5 \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k k\, x^{k+4}$

- Shift index using $k->k-4$

  $x^5 \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=4}^{\infty} a_{k-4}(k-4)\, x^k$

- Convert $\frac{d^2}{dx^2}y(x)$ to series expansion

  $\frac{d^2}{dx^2}y(x) = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$

- Shift index using $k->k+2$

  $\frac{d^2}{dx^2}y(x) = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$

  Rewrite ODE with series expansions

  $20a_5x^3 + 12a_4x^2 + 6a_3x + 2a_2 + \left(\sum_{k=4}^{\infty} \left(a_{k+2}(k+2)\,(k+1) + a_{k-4}(k+2)\right) x^k\right) = 0$

- The coefficients of each power of x must be 0

  $[2a_2 = 0, 6a_3 = 0, 12a_4 = 0, 20a_5 = 0]$

- Solve for the dependent coefficient(s)

  $\{a_2 = 0, a_3 = 0, a_4 = 0, a_5 = 0\}$

- Each term in the series must be 0, giving the recursion relation

  $(k+2)\,(ka_{k+2} + a_{k-4} + a_{k+2}) = 0$

- Shift index using $k->k+4$

  $(k+6)\,((k+4)\, a_{k+6} + a_k + a_{k+6}) = 0$

- Recursion relation that defines the series solution to the ODE

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^k, a_{k+6} = -\frac{a_k}{k+5}, a_2 = 0, a_3 = 0, a_4 = 0, a_5 = 0\right]$

2.1.68 Problem 70

Internal problem ID [9240]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 70
Date solved : `Monday, January 27, 2025 at 05:59:53 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$(1+3x)\,y''+xy'+2y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 30.965 (sec)

Writing the ode as

$$(1+3x)\,y''+xy'+2y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=1+3x\\ B&=x\\ C&=2\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned}r&=\frac{s}{t}\\ &=\frac{2AB'-2BA'+B^2-4AC}{4A^2}\end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{x^2-24x-6}{4\left(1+3x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned}s&=x^2-24x-6\\ t&=4(1+3x)^2\end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{x^2-24x-6}{4\left(1+3x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1, 2\}$,$\{1, 3\}$,$\{2\}$,$\{3\}$,$\{3, 4\}$,$\{1, 2, 5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.121: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(1 + 3x)^2$. There is a pole at $x = -\frac{1}{3}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{36} + \frac{19}{324\left(x + \frac{1}{3}\right)^2} - \frac{37}{54\left(x + \frac{1}{3}\right)}$$

For the pole at $x = -\frac{1}{3}$ let b be the coefficient of $\frac{1}{\left(x+\frac{1}{3}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{19}{324}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{19}{18} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{1}{18} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\
&= \sum_{i=0}^{0} a_i x^i
\end{aligned} \tag{8}
$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$
\sqrt{r} \approx \frac{1}{6} - \frac{37}{18x} - \frac{319}{27x^2} - \frac{11831}{81x^3} - \frac{2157901}{972x^4} - \frac{110035199}{2916x^5} - \frac{1501983319}{2187x^6} - \frac{85889060456}{6561x^7} + \dots \tag{9}
$$

Comparing Eq. (9) with Eq. (8) shows that

$$
a = \frac{1}{6}
$$

From Eq. (9) the sum up to $v = 0$ gives

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\
&= \frac{1}{6}
\end{aligned} \tag{10}
$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$
\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{36}
$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$
r = Q + \frac{R}{t}
$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{x^2 - 24x - 6}{36x^2 + 24x + 4} \\
&= Q + \frac{R}{36x^2 + 24x + 4} \\
&= \left(\frac{1}{36}\right) + \left(\frac{-\frac{74x}{3} - \frac{55}{9}}{36x^2 + 24x + 4}\right) \\
&= \frac{1}{36} + \frac{-\frac{74x}{3} - \frac{55}{9}}{36x^2 + 24x + 4}
\end{aligned}
$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is $-\frac{74}{3}$. Dividing this by leading coefficient in t which is 36 gives $-\frac{37}{54}$. Now b can be found.

$$
\begin{aligned}
b &= \left(-\frac{37}{54}\right) - (0) \\
&= -\frac{37}{54}
\end{aligned}
$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \frac{1}{6} \\
\alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{37}{54}}{\frac{1}{6}} - 0\right) &&= -\frac{37}{18} \\
\alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) = \frac{1}{2}\left(-\frac{-\frac{37}{54}}{\frac{1}{6}} - 0\right) = \frac{37}{18}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{x^2 - 24x - 6}{4\left(1+3x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
$-\frac{1}{3}$	2	0	$\frac{19}{18}$	$-\frac{1}{18}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{6}$	$-\frac{37}{18}$	$\frac{37}{18}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{37}{18}$ then

$$
\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^+\right) \\
&= \frac{37}{18} - \left(\frac{19}{18}\right) \\
&= 1
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x - c_1}\right) + (-)[\sqrt{r}]_\infty \\
&= \frac{19}{18\left(x+\frac{1}{3}\right)} + (-)\left(\frac{1}{6}\right) \\
&= \frac{19}{18\left(x+\frac{1}{3}\right)} - \frac{1}{6} \\
&= -\frac{-6+x}{2\left(1+3x\right)}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}
$$

Let

$$
p(x) = x + a_0 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(\frac{19}{18\left(x+\frac{1}{3}\right)}-\frac{1}{6}\right)(1)+\left(\left(-\frac{19}{18\left(x+\frac{1}{3}\right)^{2}}\right)+\left(\frac{19}{18\left(x+\frac{1}{3}\right)}-\frac{1}{6}\right)^{2}-\left(\frac{x^{2}-24x-6}{4\left(1+3x\right)^{2}}\right)\right)=0$$

$$\frac{a_0+6}{1+3x}=0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0=-6\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x)=-6+x$$

Therefore the first solution to the ode $z''=rz$ is

$$\begin{aligned}
z_1(x) &= pe^{\int \omega\, dx}\\
&= (-6+x)\,\mathrm{e}^{\int\left(\frac{19}{18\left(x+\frac{1}{3}\right)}-\frac{1}{6}\right)dx}\\
&= (-6+x)\,\mathrm{e}^{-\frac{x}{6}+\frac{19\ln(1+3x)}{18}}\\
&= (-6+x)\,(1+3x)^{19/18}\,\mathrm{e}^{-\frac{x}{6}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx}\\
&= z_1 e^{-\int \frac{1}{2}\frac{x}{1+3x}\, dx}\\
&= z_1 e^{-\frac{x}{6}+\frac{\ln(1+3x)}{18}}\\
&= z_1\left((1+3x)^{1/18}\,\mathrm{e}^{-\frac{x}{6}}\right)
\end{aligned}$$

Which simplifies to

$$y_1=(1+3x)^{10/9}\,\mathrm{e}^{-\frac{x}{3}}(-6+x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2=y_1\int\frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1\int\frac{e^{\int -\frac{x}{1+3x}\, dx}}{(y_1)^2}\, dx\\
&= y_1\int\frac{e^{-\frac{x}{3}+\frac{\ln(1+3x)}{9}}}{(y_1)^2}\, dx\\
&= y_1\left(\int\frac{\mathrm{e}^{-\frac{x}{3}+\frac{\ln(1+3x)}{9}}\,\mathrm{e}^{\frac{2x}{3}}}{(1+3x)^{20/9}\,(-6+x)^2}dx\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1y_1+c_2y_2\\
&= c_1\left((1+3x)^{10/9}\,\mathrm{e}^{-\frac{x}{3}}(-6+x)\right)\\
&\quad + c_2\left((1+3x)^{10/9}\,\mathrm{e}^{-\frac{x}{3}}(-6+x)\left(\int\frac{\mathrm{e}^{-\frac{x}{3}+\frac{\ln(1+3x)}{9}}\,\mathrm{e}^{\frac{2x}{3}}}{(1+3x)^{20/9}\,(-6+x)^2}dx\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$(3x+1)\left(\frac{d^2}{dx^2}y(x)\right)+x\left(\frac{d}{dx}y(x)\right)+2y(x)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x)=-\frac{2y(x)}{3x+1}-\frac{x\left(\frac{d}{dx}y(x)\right)}{3x+1}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x)+\frac{x\left(\frac{d}{dx}y(x)\right)}{3x+1}+\frac{2y(x)}{3x+1}=0$

- ☐ Check to see if $x_0=-\frac{1}{3}$ is a regular singular point
  - Define functions

    $\left[P_2(x)=\frac{x}{3x+1},P_3(x)=\frac{2}{3x+1}\right]$
  - $\left(x+\frac{1}{3}\right)\cdot P_2(x)$ is analytic at $x=-\frac{1}{3}$

    $\left(\left(x+\frac{1}{3}\right)\cdot P_2(x)\right)\bigg|_{x=-\frac{1}{3}}=-\frac{1}{9}$
  - $\left(x+\frac{1}{3}\right)^2\cdot P_3(x)$ is analytic at $x=-\frac{1}{3}$

    $\left(\left(x+\frac{1}{3}\right)^2\cdot P_3(x)\right)\bigg|_{x=-\frac{1}{3}}=0$
  - $x=-\frac{1}{3}$is a regular singular point

  Check to see if $x_0=-\frac{1}{3}$ is a regular singular point

  $x_0=-\frac{1}{3}$

- Multiply by denominators

  $(3x+1)\left(\frac{d^2}{dx^2}y(x)\right)+x\left(\frac{d}{dx}y(x)\right)+2y(x)=0$

- Change variables using $x=u-\frac{1}{3}$ so that the regular singular point is at $u=0$

  $3u\left(\frac{d^2}{du^2}y(u)\right)+\left(u-\frac{1}{3}\right)\left(\frac{d}{du}y(u)\right)+2y(u)=0$

- Assume series solution for $y(u)$

  $y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

- ☐ Rewrite ODE with series expansions
  - Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$

    $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,u^{k+r-1+m}$
  - Shift index using $k->k+1-m$

    $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,u^{k+r}$
  - Convert $u\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion

    $u\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)(k+r-1)\,u^{k+r-1}$
  - Shift index using $k->k+1$

    $u\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=-1}^{\infty}a_{k+1}(k+1+r)(k+r)\,u^{k+r}$

  Rewrite ODE with series expansions

  $\frac{a_0r(-10+9r)u^{-1+r}}{3}+\left(\sum_{k=0}^{\infty}\left(\frac{a_{k+1}(k+1+r)(9k-1+9r)}{3}+a_k(k+r+2)\right)u^{k+r}\right)=0$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $\frac{r(-10+9r)}{3} = 0$
- Values of r that satisfy the indicial equation
  $r \in \left\{0, \frac{10}{9}\right\}$
- Each term in the series must be 0, giving the recursion relation
  $3(k+1+r)\left(k-\frac{1}{9}+r\right)a_{k+1} + a_k(k+r+2) = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+1} = -\frac{3a_k(k+r+2)}{(k+1+r)(9k-1+9r)}$
- Recursion relation for $r = 0$
  $a_{k+1} = -\frac{3a_k(k+2)}{(k+1)(9k-1)}$
- Solution for $r = 0$
  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+1} = -\frac{3a_k(k+2)}{(k+1)(9k-1)}\right]$
- Revert the change of variables $u = x + \frac{1}{3}$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k \left(x+\frac{1}{3}\right)^k, a_{k+1} = -\frac{3a_k(k+2)}{(k+1)(9k-1)}\right]$
- Recursion relation for $r = \frac{10}{9}$
  $a_{k+1} = -\frac{3a_k\left(k+\frac{28}{9}\right)}{\left(k+\frac{19}{9}\right)(9k+9)}$
- Solution for $r = \frac{10}{9}$
  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+\frac{10}{9}}, a_{k+1} = -\frac{3a_k\left(k+\frac{28}{9}\right)}{\left(k+\frac{19}{9}\right)(9k+9)}\right]$
- Revert the change of variables $u = x + \frac{1}{3}$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k \left(x+\frac{1}{3}\right)^{k+\frac{10}{9}}, a_{k+1} = -\frac{3a_k\left(k+\frac{28}{9}\right)}{\left(k+\frac{19}{9}\right)(9k+9)}\right]$
- Combine solutions and rename parameters
  $\left[y(x) = \left(\sum_{k=0}^{\infty} a_k \left(x+\frac{1}{3}\right)^k\right) + \left(\sum_{k=0}^{\infty} b_k \left(x+\frac{1}{3}\right)^{k+\frac{10}{9}}\right), a_{k+1} = -\frac{3a_k(k+2)}{(k+1)(9k-1)}, b_{k+1} = -\frac{3b_k\left(k+\frac{28}{9}\right)}{\left(k+\frac{19}{9}\right)(9k+9)}\right]$

2.1.69 Problem 71

Internal problem ID [9241]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 71
Date solved : `Monday, January 27, 2025 at 06:00:25 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$\left(3x^2+x+1\right)y''+(2+15x)\,y'+12y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.763 (sec)

Writing the ode as

$$\left(3x^2+x+1\right)y''+(2+15x)\,y'+12y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A&=3x^2+x+1\\ B&=2+15x\\ C&=12 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r&=\frac{s}{t}\\ &=\frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{-9x^2-12x-18}{4\left(3x^2+x+1\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s&=-9x^2-12x-18\\ t&=4\left(3x^2+x+1\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{-9x^2-12x-18}{4\left(3x^2+x+1\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.123: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(3x^2 + x + 1)^2$. There is a pole at $x = -\frac{1}{6} + \frac{i\sqrt{11}}{6}$ of order 2. There is a pole at $x = -\frac{1}{6} - \frac{i\sqrt{11}}{6}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{\frac{27}{88} + \frac{3i\sqrt{11}}{88}}{\left(x + \frac{1}{6} - \frac{i\sqrt{11}}{6}\right)^2} + \frac{\frac{27}{88} - \frac{3i\sqrt{11}}{88}}{\left(x + \frac{1}{6} + \frac{i\sqrt{11}}{6}\right)^2} + \frac{57i\sqrt{11}}{242\left(x + \frac{1}{6} - \frac{i\sqrt{11}}{6}\right)} - \frac{57i\sqrt{11}}{242\left(x + \frac{1}{6} + \frac{i\sqrt{11}}{6}\right)}$$

For the pole at $x = -\frac{1}{6} + \frac{i\sqrt{11}}{6}$ let b be the coefficient of $\frac{1}{\left(x+\frac{1}{6}-\frac{i\sqrt{11}}{6}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{27}{88} + \frac{3i\sqrt{11}}{88}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} + \frac{\sqrt{1078 + 66i\sqrt{11}}}{44} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2} - \frac{\sqrt{1078 + 66i\sqrt{11}}}{44} \end{aligned}$$

For the pole at $x = -\frac{1}{6} - \frac{i\sqrt{11}}{6}$ let b be the coefficient of $\frac{1}{\left(x+\frac{1}{6}+\frac{i\sqrt{11}}{6}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{27}{88} - \frac{3i\sqrt{11}}{88}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} + \frac{\sqrt{1078 - 66i\sqrt{11}}}{44} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} - \frac{\sqrt{1078 - 66i\sqrt{11}}}{44}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = \frac{-9x^2 - 12x - 18}{4\left(3x^2 + x + 1\right)^2}
$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{1}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{-9x^2 - 12x - 18}{4\left(3x^2 + x + 1\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
$-\frac{1}{6} + \frac{i\sqrt{11}}{6}$	2	0	$\frac{1}{2} + \frac{\sqrt{1078+66i\sqrt{11}}}{44}$	$\frac{1}{2} - \frac{\sqrt{1078+66i\sqrt{11}}}{44}$
$-\frac{1}{6} - \frac{i\sqrt{11}}{6}$	2	0	$\frac{1}{2} + \frac{\sqrt{1078-66i\sqrt{11}}}{44}$	$\frac{1}{2} - \frac{\sqrt{1078-66i\sqrt{11}}}{44}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^-\right) \\
&= \frac{1}{2} - \left(-\frac{1}{2}\right) \\
&= 1
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2}\right) + (-)[\sqrt{r}]_\infty \\
&= \frac{\frac{1}{2}-\frac{\sqrt{1078+66i\sqrt{11}}}{44}}{x+\frac{1}{6}-\frac{i\sqrt{11}}{6}} + \frac{\frac{1}{2}-\frac{\sqrt{1078-66i\sqrt{11}}}{44}}{x+\frac{1}{6}+\frac{i\sqrt{11}}{6}} + (-)(0) \\
&= \frac{\frac{1}{2}-\frac{\sqrt{1078+66i\sqrt{11}}}{44}}{x+\frac{1}{6}-\frac{i\sqrt{11}}{6}} + \frac{\frac{1}{2}-\frac{\sqrt{1078-66i\sqrt{11}}}{44}}{x+\frac{1}{6}+\frac{i\sqrt{11}}{6}} \\
&= -\frac{3x}{6x^2+2x+2}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = x + a_0 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(0) + 2\left(\frac{\frac{1}{2}-\frac{\sqrt{1078+66i\sqrt{11}}}{44}}{x+\frac{1}{6}-\frac{i\sqrt{11}}{6}} + \frac{\frac{1}{2}-\frac{\sqrt{1078-66i\sqrt{11}}}{44}}{x+\frac{1}{6}+\frac{i\sqrt{11}}{6}}\right)(1) + \left(\left(-\frac{\frac{1}{2}-\frac{\sqrt{1078+66i\sqrt{11}}}{44}}{\left(x+\frac{1}{6}-\frac{i\sqrt{11}}{6}\right)^2} - \frac{\frac{1}{2}-\frac{\sqrt{1078-66i\sqrt{11}}}{44}}{\left(x+\frac{1}{6}+\frac{i\sqrt{11}}{6}\right)^2}\right) + \left(\frac{\frac{1}{2}-}{x}\right.\right.
$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$
\{a_0 = 0\}
$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$
p(x) = x
$$

Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= (x)\, \mathrm{e}^{\int \left(\frac{\frac{1}{2}-\frac{\sqrt{1078+66i\sqrt{11}}}{44}}{x+\frac{1}{6}-\frac{i\sqrt{11}}{6}} + \frac{\frac{1}{2}-\frac{\sqrt{1078-66i\sqrt{11}}}{44}}{x+\frac{1}{6}+\frac{i\sqrt{11}}{6}}\right) dx} \\
&= (x)\, \mathrm{e}^{-\frac{\ln\left(36x^2+12x+12\right)}{4} + \frac{\sqrt{11}\arctan\left(\frac{(6x+1)\sqrt{11}}{11}\right)}{22}} \\
&= \frac{x\sqrt{2}\, 3^{3/4} \mathrm{e}^{\frac{\sqrt{11}\arctan\left(\frac{(6x+1)\sqrt{11}}{11}\right)}{22}}}{6\left(3x^2+x+1\right)^{1/4}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{2+15x}{3x^2+x+1}\, dx} \\
&= z_1 e^{-\frac{5\ln\left(3x^2+x+1\right)}{4} + \frac{\sqrt{11}\arctan\left(\frac{(6x+1)\sqrt{11}}{11}\right)}{22}} \\
&= z_1\left(\frac{\mathrm{e}^{\frac{\sqrt{11}\arctan\left(\frac{(6x+1)\sqrt{11}}{11}\right)}{22}}}{\left(3x^2+x+1\right)^{5/4}}\right)
\end{aligned}
$$

Which simplifies to

$$y_1 = \frac{\mathrm{e}^{\frac{\sqrt{11}\, \arctan\left(\frac{(6x+1)\sqrt{11}}{11}\right)}{11}} x\sqrt{2}\, 3^{3/4}}{6\left(3x^2+x+1\right)^{3/2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{2+15x}{3x^2+x+1}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-\frac{5\ln\left(3x^2+x+1\right)}{2}+\frac{\sqrt{11}\, \arctan\left(\frac{(6x+1)\sqrt{11}}{11}\right)}{11}}}{(y_1)^2}\, dx \\
&= y_1 \left(\int \frac{2\,\mathrm{e}^{-\frac{5\ln\left(3x^2+x+1\right)}{2}+\frac{\sqrt{11}\, \arctan\left(\frac{(6x+1)\sqrt{11}}{11}\right)}{11}} \left(3x^2+x+1\right)^3 \mathrm{e}^{-\frac{2\sqrt{11}\, \arctan\left(\frac{(6x+1)\sqrt{11}}{11}\right)}{11}} \sqrt{3}}{x^2} dx\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{\mathrm{e}^{\frac{\sqrt{11}\, \arctan\left(\frac{(6x+1)\sqrt{11}}{11}\right)}{11}} x\sqrt{2}\, 3^{3/4}}{6\left(3x^2+x+1\right)^{3/2}}\right) \\
&+ c_2 \left(\frac{\mathrm{e}^{\frac{\sqrt{11}\, \arctan\left(\frac{(6x+1)\sqrt{11}}{11}\right)}{11}} x\sqrt{2}\, 3^{3/4}}{6\left(3x^2+x+1\right)^{3/2}} \left(\int \frac{2\,\mathrm{e}^{-\frac{5\ln\left(3x^2+x+1\right)}{2}+\frac{\sqrt{11}\, \arctan\left(\frac{(6x+1)\sqrt{11}}{11}\right)}{11}} \left(3x^2+x+1\right)^3 \mathrm{e}^{-\frac{2\sqrt{11}\, \arctan\left(\frac{(6x+1)\sqrt{11}}{11}\right)}{11}}}{x^2}\right.\right.
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$\left(3x^2+x+1\right)\left(\frac{d^2}{dx^2}y(x)\right) + (2+15x)\left(\frac{d}{dx}y(x)\right) + 12y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{12y(x)}{3x^2+x+1} - \frac{(2+15x)\left(\frac{d}{dx}y(x)\right)}{3x^2+x+1}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x) + \frac{(2+15x)\left(\frac{d}{dx}y(x)\right)}{3x^2+x+1} + \frac{12y(x)}{3x^2+x+1} = 0$

☐ Check to see if x_0 is a regular singular point

- ○ Define functions

  $\left[P_2(x) = \frac{2+15x}{3x^2+x+1}, P_3(x) = \frac{12}{3x^2+x+1}\right]$

- ○ $\left(\frac{\mathrm{I}\sqrt{11}}{6}+x+\frac{1}{6}\right)\cdot P_2(x)$ is analytic at $x = -\frac{1}{6}-\frac{\mathrm{I}\sqrt{11}}{6}$

$\left(\left(\frac{\mathrm{I}\sqrt{11}}{6}+x+\frac{1}{6}\right)\cdot P_2(x)\right)\Big|_{x=-\frac{1}{6}-\frac{\mathrm{I}\sqrt{11}}{6}}=0$

- $\left(\frac{\mathrm{I}\sqrt{11}}{6}+x+\frac{1}{6}\right)^2\cdot P_3(x)$ is analytic at $x=-\frac{1}{6}-\frac{\mathrm{I}\sqrt{11}}{6}$

  $\left(\left(\frac{\mathrm{I}\sqrt{11}}{6}+x+\frac{1}{6}\right)^2\cdot P_3(x)\right)\Big|_{x=-\frac{1}{6}-\frac{\mathrm{I}\sqrt{11}}{6}}=0$

- $x=-\frac{1}{6}-\frac{\mathrm{I}\sqrt{11}}{6}$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=-\frac{1}{6}-\frac{\mathrm{I}\sqrt{11}}{6}$

- Multiply by denominators

  $(3x^2+x+1)\left(\frac{d^2}{dx^2}y(x)\right)+(2+15x)\left(\frac{d}{dx}y(x)\right)+12y(x)=0$

- Change variables using $x=u-\frac{1}{6}-\frac{\mathrm{I}\sqrt{11}}{6}$ so that the regular singular point is at $u=0$

  $(3u^2-\mathrm{I}u\sqrt{11})\left(\frac{d^2}{du^2}y(u)\right)+\left(-\frac{1}{2}+15u-\frac{5\,\mathrm{I}\sqrt{11}}{2}\right)\left(\frac{d}{du}y(u)\right)+12y(u)=0$

- Assume series solution for $y(u)$

  $y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

- ☐ Rewrite ODE with series expansions
  - Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$

    $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,u^{k+r-1+m}$
  - Shift index using $k->k+1-m$

    $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,u^{k+r}$
  - Convert $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m=1..2$

    $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)(k+r-1)\,u^{k+r-2+m}$
  - Shift index using $k->k+2-m$

    $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=-2+m}^{\infty}a_{k+2-m}(k+2-m+r)(k+1-m+r)\,u^{k+r}$

  Rewrite ODE with series expansions

  $\frac{\mathrm{I}\sqrt{11}\,r\left(\mathrm{I}\sqrt{11}-33-22r\right)a_0u^{-1+r}}{22}+\left(\sum_{k=0}^{\infty}\left(\frac{\mathrm{I}\sqrt{11}\,(k+1+r)\left(\mathrm{I}\sqrt{11}-22k-55-22r\right)a_{k+1}}{22}+3a_k(k+r+2)^2\right)u^{k+r}\right)=0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $\frac{\mathrm{I}}{22}\sqrt{11}\,r\left(\mathrm{I}\sqrt{11}-33-22r\right)=0$

- Values of r that satisfy the indicial equation

  $r\in\left\{0,-\frac{3}{2}+\frac{\mathrm{I}\sqrt{11}}{22}\right\}$

- Each term in the series must be 0, giving the recursion relation

  $3a_k(k+r+2)^2-(k+1+r)\,a_{k+1}\left(\frac{1}{2}+\mathrm{I}\left(k+r+\frac{5}{2}\right)\sqrt{11}\right)=0$

- Recursion relation that defines series solution to ODE

  $a_{k+1}=\frac{6a_k\left(k^2+2kr+r^2+4k+4r+4\right)}{2\,\mathrm{I}\sqrt{11}\,k^2+4\,\mathrm{I}kr\sqrt{11}+2\,\mathrm{I}\sqrt{11}\,r^2+7\,\mathrm{I}k\sqrt{11}+7\,\mathrm{I}r\sqrt{11}+5\,\mathrm{I}\sqrt{11}+k+r+1}$

- Recursion relation for $r=0$

  $a_{k+1}=\frac{6a_k\left(k^2+4k+4\right)}{2\,\mathrm{I}\sqrt{11}\,k^2+1+7\,\mathrm{I}k\sqrt{11}+5\,\mathrm{I}\sqrt{11}+k}$

- Solution for $r=0$

  $\left[y(u)=\sum_{k=0}^{\infty}a_k u^k, a_{k+1}=\frac{6a_k\left(k^2+4k+4\right)}{2\,\mathrm{I}\sqrt{11}\,k^2+1+7\,\mathrm{I}k\sqrt{11}+5\,\mathrm{I}\sqrt{11}+k}\right]$

- Revert the change of variables $u=\frac{I\sqrt{11}}{6}+x+\frac{1}{6}$

$$\left[y(x)=\sum_{k=0}^{\infty}a_k\left(\frac{I\sqrt{11}}{6}+x+\frac{1}{6}\right)^k, a_{k+1}=\frac{6a_k(k^2+4k+4)}{2I\sqrt{11}\,k^2+1+7Ik\sqrt{11}+5I\sqrt{11}+k}\right]$$

- Recursion relation for $r=-\frac{3}{2}+\frac{I\sqrt{11}}{22}$

$$a_{k+1}=\frac{6a_k\left(k^2+2k\left(-\frac{3}{2}+\frac{I\sqrt{11}}{22}\right)+\left(-\frac{3}{2}+\frac{I\sqrt{11}}{22}\right)^2+4k-2+\frac{2I\sqrt{11}}{11}\right)}{2I\sqrt{11}\,k^2+4Ik\left(-\frac{3}{2}+\frac{I\sqrt{11}}{22}\right)\sqrt{11}+2I\sqrt{11}\left(-\frac{3}{2}+\frac{I\sqrt{11}}{22}\right)^2+7Ik\sqrt{11}+7I\left(-\frac{3}{2}+\frac{I\sqrt{11}}{22}\right)\sqrt{11}+\frac{111I\sqrt{11}}{22}+k-\frac{1}{2}}$$

- Solution for $r=-\frac{3}{2}+\frac{I\sqrt{11}}{22}$

$$\left[y(u)=\sum_{k=0}^{\infty}a_k u^{k-\frac{3}{2}+\frac{I\sqrt{11}}{22}}, a_{k+1}=\frac{6a_k\left(k^2+2k\left(-\frac{3}{2}+\frac{I\sqrt{11}}{22}\right)+\left(-\frac{3}{2}+\frac{I\sqrt{11}}{22}\right)^2+4k-2+\frac{2I\sqrt{11}}{11}\right)}{2I\sqrt{11}\,k^2+4Ik\left(-\frac{3}{2}+\frac{I\sqrt{11}}{22}\right)\sqrt{11}+2I\sqrt{11}\left(-\frac{3}{2}+\frac{I\sqrt{11}}{22}\right)^2+7Ik\sqrt{11}+7I\left(-\frac{3}{2}+\frac{I\sqrt{11}}{22}\right)\sqrt{11}\right.$$

- Revert the change of variables $u=\frac{I\sqrt{11}}{6}+x+\frac{1}{6}$

$$\left[y(x)=\sum_{k=0}^{\infty}a_k\left(\frac{I\sqrt{11}}{6}+x+\frac{1}{6}\right)^{k-\frac{3}{2}+\frac{I\sqrt{11}}{22}}, a_{k+1}=\frac{6a_k\left(k^2+2k\left(-\frac{3}{2}+\frac{I\sqrt{11}}{22}\right)+\left(-\frac{3}{2}+\frac{I\sqrt{11}}{22}\right)^2+4\right.}{2I\sqrt{11}\,k^2+4Ik\left(-\frac{3}{2}+\frac{I\sqrt{11}}{22}\right)\sqrt{11}+2I\sqrt{11}\left(-\frac{3}{2}+\frac{I\sqrt{11}}{22}\right)^2+7Ik\sqrt{11}+}\right.$$

- Combine solutions and rename parameters

$$\left[y(x)=\left(\sum_{k=0}^{\infty}a_k\left(\frac{I\sqrt{11}}{6}+x+\frac{1}{6}\right)^k\right)+\left(\sum_{k=0}^{\infty}b_k\left(\frac{I\sqrt{11}}{6}+x+\frac{1}{6}\right)^{k-\frac{3}{2}+\frac{I\sqrt{11}}{22}}\right), a_{k+1}=\frac{6a_k(k^2+4k+}{2I\sqrt{11}\,k^2+1+7Ik\sqrt{11}}\right.$$

CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$(2+x)\,y''+(1+x)\,y'+3y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.286 (sec)

Writing the ode as

$$(2+x)\,y''+(1+x)\,y'+3y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A&=2+x\\ B&=1+x\\ C&=3 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r&=\frac{s}{t}\\ &=\frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{x^2-10x-21}{4\,(2+x)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s&=x^2-10x-21\\ t&=4(2+x)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{x^2-10x-21}{4\,(2+x)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.125: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(2+x)^2$. There is a pole at $x = -2$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} - \frac{7}{2\,(2+x)} + \frac{3}{4\,(2+x)^2}$$

For the pole at $x = -2$ let b be the coefficient of $\frac{1}{(2+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\
&= \sum_{i=0}^{0} a_i x^i
\end{aligned} \tag{8}
$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$
\sqrt{r} \approx \frac{1}{2} - \frac{7}{2x} - \frac{9}{2x^2} - \frac{97}{2x^3} - \frac{1291}{4x^4} - \frac{11103}{4x^5} - \frac{98061}{4x^6} - \frac{913053}{4x^7} + \dots \tag{9}
$$

Comparing Eq. (9) with Eq. (8) shows that

$$
a = \frac{1}{2}
$$

From Eq. (9) the sum up to $v = 0$ gives

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\
&= \frac{1}{2}
\end{aligned} \tag{10}
$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$
\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}
$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$
r = Q + \frac{R}{t}
$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{x^2 - 10x - 21}{4x^2 + 16x + 16} \\
&= Q + \frac{R}{4x^2 + 16x + 16} \\
&= \left(\frac{1}{4}\right) + \left(\frac{-14x - 25}{4x^2 + 16x + 16}\right) \\
&= \frac{1}{4} + \frac{-14x - 25}{4x^2 + 16x + 16}
\end{aligned}
$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is -14. Dividing this by leading coefficient in t which is 4 gives $-\frac{7}{2}$. Now b can be found.

$$
\begin{aligned}
b &= \left(-\frac{7}{2}\right) - (0) \\
&= -\frac{7}{2}
\end{aligned}
$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \frac{1}{2} \\
\alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-\frac{7}{2}}{\frac{1}{2}} - 0\right) &= -\frac{7}{2} \\
\alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-\frac{7}{2}}{\frac{1}{2}} - 0\right) &= \frac{7}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{x^2 - 10x - 21}{4\left(2+x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
-2	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
0	$\frac{1}{2}$	$-\frac{7}{2}$	$\frac{7}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = \frac{7}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^{-} - \left(\alpha_{c_1}^{+}\right) \\
&= \frac{7}{2} - \left(\frac{3}{2}\right) \\
&= 2
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\
&= \frac{3}{2\left(2+x\right)} + (-)\left(\frac{1}{2}\right) \\
&= \frac{3}{2\left(2+x\right)} - \frac{1}{2} \\
&= -\frac{-1+x}{2\left(2+x\right)}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 2$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}
$$

Let

$$
p(x) = x^2 + a_1 x + a_0 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$(2)+2\left(\frac{3}{2(2+x)}-\frac{1}{2}\right)(2x+a_1)+\left(\left(-\frac{3}{2(2+x)^2}\right)+\left(\frac{3}{2(2+x)}-\frac{1}{2}\right)^2-\left(\frac{x^2-10x-21}{4(2+x)^2}\right)\right)=0$$

$$\frac{(a_1+4)x+2a_0+a_1+4}{2+x}=0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0=0, a_1=-4\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x)=x^2-4x$$

Therefore the first solution to the ode $z''=rz$ is

$$\begin{aligned}
z_1(x) &= pe^{\int \omega\,dx} \\
&= (x^2-4x)\,\mathrm{e}^{\int\left(\frac{3}{2(2+x)}-\frac{1}{2}\right)dx} \\
&= (x^2-4x)\,\mathrm{e}^{-\frac{x}{2}+\frac{3\ln(2+x)}{2}} \\
&= x(x-4)(2+x)^{3/2}\,\mathrm{e}^{-\frac{x}{2}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{1+x}{2+x}\,dx} \\
&= z_1 e^{-\frac{x}{2}+\frac{\ln(2+x)}{2}} \\
&= z_1\left(\sqrt{2+x}\,\mathrm{e}^{-\frac{x}{2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1=(2+x)^2\,\mathrm{e}^{-x}x(x-4)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2=y_1\int\frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1\int\frac{e^{\int -\frac{1+x}{2+x}\,dx}}{(y_1)^2}\,dx \\
&= y_1\int\frac{e^{-x+\ln(2+x)}}{(y_1)^2}\,dx \\
&= y_1\left(-\frac{\mathrm{e}^{-2}\,\mathrm{Ei}_1(-2-x)}{48}-\frac{\mathrm{e}^{x}}{288(2+x)^2}-\frac{11\,\mathrm{e}^{x}}{864(2+x)}-\frac{\mathrm{e}^{x}}{3456(x-4)}-\frac{\mathrm{e}^{x}}{128x}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1y_1+c_2y_2 \\
&= c_1\left((2+x)^2\,\mathrm{e}^{-x}x(x-4)\right)+c_2\left((2+x)^2\,\mathrm{e}^{-x}x(x-4)\left(-\frac{\mathrm{e}^{-2}\,\mathrm{Ei}_1(-2-x)}{48}-\frac{\mathrm{e}^{x}}{288(2+x)^2}\right.\right. \\
&\quad \left.\left.-\frac{11\,\mathrm{e}^{x}}{864(2+x)}-\frac{\mathrm{e}^{x}}{3456(x-4)}-\frac{\mathrm{e}^{x}}{128x}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$(x+2)\left(\frac{d^2}{dx^2}y(x)\right)+(x+1)\left(\frac{d}{dx}y(x)\right)+3y(x)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$
- Isolate 2nd derivative

CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$(4+x)\,y''+(2+x)\,y'+2y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.276 (sec)

Writing the ode as

$$(4+x)\,y''+(2+x)\,y'+2y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=4+x\\B&=2+x\\C&=2\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned}r&=\frac{s}{t}\\&=\frac{2AB'-2BA'+B^2-4AC}{4A^2}\end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{x^2-4x-24}{4\,(4+x)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned}s&=x^2-4x-24\\t&=4(4+x)^2\end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{x^2-4x-24}{4\,(4+x)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.127: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(4+x)^2$. There is a pole at $x = -4$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

<u>Attempting to find a solution using case $n = 1$.</u>

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} + \frac{2}{(4+x)^2} - \frac{3}{4+x}$$

For the <u>pole at $x = -4$</u> let b be the coefficient of $\frac{1}{(4+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1 \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} - \frac{3}{x} + \frac{5}{x^2} - \frac{34}{x^3} + \frac{59}{x^4} - \frac{586}{x^5} + \frac{370}{x^6} - \frac{12484}{x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 - 4x - 24}{4x^2 + 32x + 64} \\ &= Q + \frac{R}{4x^2 + 32x + 64} \\ &= \left(\frac{1}{4}\right) + \left(\frac{-12x - 40}{4x^2 + 32x + 64}\right) \\ &= \frac{1}{4} + \frac{-12x - 40}{4x^2 + 32x + 64} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is -12. Dividing this by leading coefficient in t which is 4 gives -3. Now b can be found.

$$\begin{aligned} b &= (-3) - (0) \\ &= -3 \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-3}{\frac{1}{2}} - 0\right) &&= -3 \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-3}{\frac{1}{2}} - 0\right) &&= 3 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2 - 4x - 24}{4\left(4+x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
-4	2	0	2	-1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	-3	3

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 3$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^+\right) \\
&= 3 - (2) \\
&= 1
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\
&= \frac{2}{4+x} + (-)\left(\frac{1}{2}\right) \\
&= \frac{2}{4+x} - \frac{1}{2} \\
&= -\frac{x}{2\left(4+x\right)}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned}
(0) + 2\left(\frac{2}{4+x} - \frac{1}{2}\right)(1) + \left(\left(-\frac{2}{\left(4+x\right)^2}\right) + \left(\frac{2}{4+x} - \frac{1}{2}\right)^2 - \left(\frac{x^2-4x-24}{4\left(4+x\right)^2}\right) \right) &= 0 \\
\frac{a_0}{4+x} &= 0
\end{aligned}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= (x) \, e^{\int \left(\frac{2}{4+x} - \frac{1}{2}\right) dx} \\ &= (x) \, e^{-\frac{x}{2} + 2\ln(4+x)} \\ &= x(4+x)^2 \, e^{-\frac{x}{2}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{2+x}{4+x} \, dx} \\ &= z_1 e^{-\frac{x}{2} + \ln(4+x)} \\ &= z_1 \left((4+x) \, e^{-\frac{x}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = (4+x)^3 \, e^{-x} x$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{2+x}{4+x} \, dx}}{(y_1)^2} \, dx \\ &= y_1 \int \frac{e^{-x + 2\ln(4+x)}}{(y_1)^2} \, dx \\ &= y_1 \left(-\frac{29 \, e^{x}}{768 \, (4+x)} - \frac{e^{-4} \, \mathrm{Ei}_1(-4-x)}{24} - \frac{5 \, e^{x}}{192 \, (4+x)^2} - \frac{e^{x}}{48 \, (4+x)^3} - \frac{e^{x}}{256x} \right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left((4+x)^3 \, e^{-x} x\right) + c_2 \left((4+x)^3 \, e^{-x} x \left(-\frac{29 \, e^{x}}{768 \, (4+x)} - \frac{e^{-4} \, \mathrm{Ei}_1(-4-x)}{24} - \frac{5 \, e^{x}}{192 \, (4+x)^2} \right.\right. \\ &\quad \left.\left. - \frac{e^{x}}{48 \, (4+x)^3} - \frac{e^{x}}{256x} \right) \right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$$y(x) \to x \exp \left(\int_1^x -\frac{K[1]}{2(K[1]+4)} dK[1] - \frac{1}{2} \int_1^x \frac{K[2]+2}{K[2]+4} dK[2] \right) \left(c_2 \int_1^x \frac{\exp \left(-2 \int_1^{K[3]} -\frac{K[1]}{2(K[1]+4)} dK[1] \right)}{K[3]^2} dK[3] + c_1 \right)$$

2.1.72 Problem 74

Internal problem ID [9244]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 74
Date solved : `Monday, January 27, 2025 at 06:00:27 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$\left(2x^2+3x\right)y''+10(1+x)\,y'+8y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.290 (sec)

Writing the ode as

$$\left(2x^2+3x\right)y''+(10x+10)\,y'+8y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A&=2x^2+3x\\ B&=10x+10\\ C&=8 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r&=\frac{s}{t}\\ &=\frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{-x^2+6x+10}{\left(2x^2+3x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s&=-x^2+6x+10\\ t&=\left(2x^2+3x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{-x^2+6x+10}{\left(2x^2+3x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.129: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (2x^2 + 3x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -\frac{3}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{5}{36\left(x+\frac{3}{2}\right)^2} + \frac{22}{27\left(x+\frac{3}{2}\right)} - \frac{22}{27x} + \frac{10}{9x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{10}{9}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{3} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{2}{3} \end{aligned}$$

For the pole at $x = -\frac{3}{2}$ let b be the coefficient of $\frac{1}{\left(x+\frac{3}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{5}{36}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{6} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{6} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{-x^2 + 6x + 10}{(2x^2 + 3x)^2}$$

Since the gcd$(s,t) = 1$. This gives $b = -\frac{1}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{-x^2 + 6x + 10}{(2x^2 + 3x)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{5}{3}$	$-\frac{2}{3}$
$-\frac{3}{2}$	2	0	$\frac{5}{6}$	$\frac{1}{6}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^-\right) \\
&= \frac{1}{2} - \left(-\frac{1}{2}\right) \\
&= 1
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2} \right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{2}{3x} + \frac{1}{6x+9} + (-)(0) \\
&= -\frac{2}{3x} + \frac{1}{6x+9} \\
&= -\frac{x+2}{x(2x+3)}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{2}{3x} + \frac{1}{6x+9}\right)(1) + \left(\left(\frac{2}{3x^2} - \frac{1}{6\left(x+\frac{3}{2}\right)^2}\right) + \left(-\frac{2}{3x} + \frac{1}{6x+9}\right)^2 - \left(\frac{-x^2+6x+10}{\left(2x^2+3x\right)^2}\right)\right) = 0$$

$$\frac{-4 + 2a_0}{x\left(2x+3\right)} = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 2\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x + 2$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= (x+2)\,\mathrm{e}^{\int \left(-\frac{2}{3x} + \frac{1}{6x+9}\right) dx} \\
&= (x+2)\,\mathrm{e}^{\frac{\ln(2x+3)}{6} - \frac{2\ln(x)}{3}} \\
&= \frac{(x+2)\left(2x+3\right)^{1/6}}{x^{2/3}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{10x+10}{2x^2+3x}\, dx} \\
&= z_1 e^{-\frac{5\ln(2x+3)}{6} - \frac{5\ln(x)}{3}} \\
&= z_1 \left(\frac{1}{\left(2x+3\right)^{5/6} x^{5/3}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{x+2}{\left(2x+3\right)^{2/3} x^{7/3}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{10x+10}{2x^2+3x}\, dx}}{\left(y_1\right)^2}\, dx \\
&= y_1 \int \frac{\mathrm{e}^{-\frac{5\ln(2x+3)}{3} - \frac{10\ln(x)}{3}}}{\left(y_1\right)^2}\, dx \\
&= y_1 \left(\int \frac{\mathrm{e}^{-\frac{5\ln(2x+3)}{3} - \frac{10\ln(x)}{3}} \left(2x+3\right)^{4/3} x^{14/3}}{\left(x+2\right)^2}\, dx\right)
\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{x+2}{(2x+3)^{2/3}\, x^{7/3}}\right) + c_2\left(\frac{x+2}{(2x+3)^{2/3}\, x^{7/3}}\left(\int \frac{e^{-\frac{5\ln(2x+3)}{3}-\frac{10\ln(x)}{3}}(2x+3)^{4/3}\, x^{14/3}}{(x+2)^2}dx\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$(2x^2+3x)\left(\frac{d^2}{dx^2}y(x)\right)+10(x+1)\left(\frac{d}{dx}y(x)\right)+8y(x)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$
- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x)=-\frac{8y(x)}{x(2x+3)}-\frac{10(x+1)\left(\frac{d}{dx}y(x)\right)}{x(2x+3)}$
- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x)+\frac{10(x+1)\left(\frac{d}{dx}y(x)\right)}{x(2x+3)}+\frac{8y(x)}{x(2x+3)}=0$
- □ Check to see if x_0 is a regular singular point
  - Define functions

    $\left[P_2(x)=\frac{10(x+1)}{x(2x+3)}, P_3(x)=\frac{8}{x(2x+3)}\right]$
  - $x\cdot P_2(x)$ is analytic at $x=0$

    $\left.(x\cdot P_2(x))\right|_{x=0}=\frac{10}{3}$
  - $x^2\cdot P_3(x)$ is analytic at $x=0$

    $\left.(x^2\cdot P_3(x))\right|_{x=0}=0$
  - $x=0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=0$
- Multiply by denominators

  $x(2x+3)\left(\frac{d^2}{dx^2}y(x)\right)+(10x+10)\left(\frac{d}{dx}y(x)\right)+8y(x)=0$
- Assume series solution for $y(x)$

  $y(x)=\sum_{k=0}^{\infty} a_k x^{k+r}$
- □ Rewrite ODE with series expansions
  - Convert $x^m\cdot\left(\frac{d}{dx}y(x)\right)$ to series expansion for $m=0..1$

    $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1+m}$
  - Shift index using $k->k+1-m$

    $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$
  - Convert $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m=1..2$

    $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, x^{k+r-2+m}$
  - Shift index using $k->k+2-m$

$$x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$$

Rewrite ODE with series expansions

$$a_0 r(7+3r)\,x^{-1+r} + \left(\sum_{k=0}^{\infty} \left(a_{k+1}(k+1+r)\,(3k+10+3r) + 2a_k(k+r+2)^2\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $r(7+3r) = 0$
- Values of r that satisfy the indicial equation
  $r \in \left\{0, -\frac{7}{3}\right\}$
- Each term in the series must be 0, giving the recursion relation
  $a_{k+1}(k+1+r)\,(3k+10+3r) + 2a_k(k+r+2)^2 = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+1} = -\frac{2a_k(k+r+2)^2}{(k+1+r)(3k+10+3r)}$
- Recursion relation for $r = 0$
  $a_{k+1} = -\frac{2a_k(k+2)^2}{(k+1)(3k+10)}$
- Solution for $r = 0$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^k, a_{k+1} = -\frac{2a_k(k+2)^2}{(k+1)(3k+10)}\right]$
- Recursion relation for $r = -\frac{7}{3}$
  $a_{k+1} = -\frac{2a_k\left(k-\frac{1}{3}\right)^2}{\left(k-\frac{4}{3}\right)(3k+3)}$
- Solution for $r = -\frac{7}{3}$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k-\frac{7}{3}}, a_{k+1} = -\frac{2a_k\left(k-\frac{1}{3}\right)^2}{\left(k-\frac{4}{3}\right)(3k+3)}\right]$
- Combine solutions and rename parameters
  $\left[y(x) = \left(\sum_{k=0}^{\infty} a_k x^k\right) + \left(\sum_{k=0}^{\infty} b_k x^{k-\frac{7}{3}}\right), a_{k+1} = -\frac{2a_k(k+2)^2}{(k+1)(3k+10)}, b_{k+1} = -\frac{2b_k\left(k-\frac{1}{3}\right)^2}{\left(k-\frac{4}{3}\right)(3k+3)}\right]$

2.1.73 Problem 75

Internal problem ID [9245]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 75
Date solved : `Monday, January 27, 2025 at 06:00:28 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' - (6-7x)\,y' + 8y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.263 (sec)

Writing the ode as

$$x^2y'' + (-6+7x)\,y' + 8y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -6+7x \\ C &= 8 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{3x^2 - 60x + 36}{4x^4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 3x^2 - 60x + 36 \\ t &= 4x^4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{3x^2 - 60x + 36}{4x^4}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.131: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^4$. There is a pole at $x = 0$ of order 4. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Looking at higher order poles of order $2v \geq 4$ (must be even order for case one).Then for each pole c, $[\sqrt{r}]_c$ is the sum of terms $\frac{1}{(x-c)^i}$ for $2 \leq i \leq v$ in the Laurent series expansion of $\sqrt{r}$ expanded around each pole c. Hence

$$[\sqrt{r}]_c = \sum_{2}^{v} \frac{a_i}{(x-c)^i} \tag{1B}$$

Let a be the coefficient of the term $\frac{1}{(x-c)^v}$ in the above where v is the pole order divided by 2. Let b be the coefficient of $\frac{1}{(x-c)^{v+1}}$ in r minus the coefficient of $\frac{1}{(x-c)^{v+1}}$ in $[\sqrt{r}]_c$. Then

$$\begin{aligned} \alpha_c^+ &= \frac{1}{2}\left(\frac{b}{a} + v\right) \\ \alpha_c^- &= \frac{1}{2}\left(-\frac{b}{a} + v\right) \end{aligned}$$

The partial fraction decomposition of r is

$$r = -\frac{15}{x^3} + \frac{3}{4x^2} + \frac{9}{x^4}$$

There is pole in r at $x = 0$ of order 4, hence $v = 2$. Expanding $\sqrt{r}$ as Laurent series about this pole $c = 0$ gives

$$[\sqrt{r}]_c \approx \frac{3}{x^2} - \frac{5}{2x} - \frac{11}{12} - \frac{55x}{72} - \frac{671x^2}{864} - \frac{4565x^3}{5184} + \dots \tag{2B}$$

Using eq. (1B), taking the sum up to $v = 2$ the above becomes

$$[\sqrt{r}]_c = \frac{3}{x^2} \tag{3B}$$

The above shows that the coefficient of $\frac{1}{(x-0)^2}$ is

$$a = 3$$

Now we need to find b. let b be the coefficient of the term $\frac{1}{(x-c)^{v+1}}$ in r minus the coefficient of the same term but in the sum $[\sqrt{r}]_c$ found in eq. (3B). Here c is current pole which is $c = 0$. This term becomes $\frac{1}{x^3}$. The coefficient of this term in the sum $[\sqrt{r}]_c$ is seen to be 0 and the coefficient of this term r is found from the partial fraction decomposition from above to be -15. Therefore

$$\begin{aligned} b &= (-15) - (0) \\ &= -15 \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_c &= \frac{3}{x^2} \\ \alpha_c^+ &= \frac{1}{2}\left(\frac{b}{a} + v\right) &= \frac{1}{2}\left(\frac{-15}{3} + 2\right) &= -\frac{3}{2} \\ \alpha_c^- &= \frac{1}{2}\left(-\frac{b}{a} + v\right) = \frac{1}{2}\left(-\frac{-15}{3} + 2\right) = \frac{7}{2} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{3x^2 - 60x + 36}{4x^4}$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{3x^2 - 60x + 36}{4x^4}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	4	$\frac{3}{x^2}$	$-\frac{3}{2}$	$\frac{7}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -\frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^+\right) \\
&= -\frac{1}{2} - \left(-\frac{3}{2}\right) \\
&= 1
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\
&= \frac{3}{x^2} - \frac{3}{2x} + (-)\,(0) \\
&= \frac{3}{x^2} - \frac{3}{2x} \\
&= -\frac{3(-2+x)}{2x^2}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = x + a_0 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(0) + 2\left(\frac{3}{x^2} - \frac{3}{2x}\right)(1) + \left(\left(-\frac{6}{x^3} + \frac{3}{2x^2}\right) + \left(\frac{3}{x^2} - \frac{3}{2x}\right)^2 - \left(\frac{3x^2 - 60x + 36}{4x^4}\right)\right) = 0
$$

$$
\frac{6 + 3a_0}{x^2} = 0
$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$
\{a_0 = -2\}
$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$
p(x) = -2 + x
$$

Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx} \\
&= (-2+x)\, e^{\int \left(\frac{3}{x^2} - \frac{3}{2x}\right) dx} \\
&= (-2+x)\, e^{-\frac{3\ln(x)}{2} - \frac{3}{x}} \\
&= \frac{(-2+x)\, e^{-\frac{3}{x}}}{x^{3/2}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-6+7x}{x^2}\,dx} \\
&= z_1 e^{-\frac{7\ln(x)}{2}-\frac{3}{x}} \\
&= z_1 \left(\frac{\mathrm{e}^{-\frac{3}{x}}}{x^{7/2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{\mathrm{e}^{-\frac{6}{x}}(-2+x)}{x^5}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-6+7x}{x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-7\ln(x)-\frac{6}{x}}}{(y_1)^2}\,dx \\
&= y_1 \left(\frac{12\,\mathrm{e}^{\frac{6}{x}}}{\frac{6}{x}-3} + 54\,\mathrm{Ei}_1\left(-\frac{6}{x}\right) + \frac{x^2\mathrm{e}^{\frac{6}{x}}}{2} + 7x\,\mathrm{e}^{\frac{6}{x}}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{\mathrm{e}^{-\frac{6}{x}}(-2+x)}{x^5}\right) + c_2 \left(\frac{\mathrm{e}^{-\frac{6}{x}}(-2+x)}{x^5}\left(\frac{12\,\mathrm{e}^{\frac{6}{x}}}{\frac{6}{x}-3} + 54\,\mathrm{Ei}_1\left(-\frac{6}{x}\right) + \frac{x^2\mathrm{e}^{\frac{6}{x}}}{2} + 7x\,\mathrm{e}^{\frac{6}{x}}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Book : Collection of Kovacic problems
Section : section 1
Problem number : 76
Date solved : `Monday, January 27, 2025 at 06:00:29 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$\left(2x^2+x+1\right)y''+(1+7x)\,y'+2y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.984 (sec)

Writing the ode as

$$\left(2x^2+x+1\right)y''+(1+7x)\,y'+2y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2x^2+x+1 \\ B &= 1+7x \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{5x^2-2x+5}{4\left(2x^2+x+1\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 5x^2-2x+5 \\ t &= 4\left(2x^2+x+1\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{5x^2-2x+5}{4\left(2x^2+x+1\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.132: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(2x^2 + x + 1)^2$. There is a pole at $x = -\frac{1}{4} + \frac{i\sqrt{7}}{4}$ of order 2. There is a pole at $x = -\frac{1}{4} - \frac{i\sqrt{7}}{4}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{-\frac{29}{224} + \frac{9i\sqrt{7}}{224}}{\left(x + \frac{1}{4} - \frac{i\sqrt{7}}{4}\right)^2} + \frac{-\frac{29}{224} - \frac{9i\sqrt{7}}{224}}{\left(x + \frac{1}{4} + \frac{i\sqrt{7}}{4}\right)^2} - \frac{8i\sqrt{7}}{49\left(x + \frac{1}{4} - \frac{i\sqrt{7}}{4}\right)} + \frac{8i\sqrt{7}}{49\left(x + \frac{1}{4} + \frac{i\sqrt{7}}{4}\right)}$$

For the pole at $x = -\frac{1}{4} + \frac{i\sqrt{7}}{4}$ let b be the coefficient of $\frac{1}{\left(x+\frac{1}{4}-\frac{i\sqrt{7}}{4}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{29}{224} + \frac{9i\sqrt{7}}{224}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} + \frac{3\sqrt{42 + 14i\sqrt{7}}}{56} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2} - \frac{3\sqrt{42 + 14i\sqrt{7}}}{56} \end{aligned}$$

For the pole at $x=-\frac{1}{4}-\frac{i\sqrt{7}}{4}$ let b be the coefficient of $\frac{1}{\left(x+\frac{1}{4}+\frac{i\sqrt{7}}{4}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b=-\frac{29}{224}-\frac{9i\sqrt{7}}{224}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0\\
\alpha_c^+ &= \frac{1}{2}+\sqrt{1+4b}=\frac{1}{2}+\frac{3\sqrt{42-14i\sqrt{7}}}{56}\\
\alpha_c^- &= \frac{1}{2}-\sqrt{1+4b}=\frac{1}{2}-\frac{3\sqrt{42-14i\sqrt{7}}}{56}
\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty=0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r=\frac{s}{t}=\frac{5x^2-2x+5}{4\left(2x^2+x+1\right)^2}$$

Since the $\gcd(s,t)=1$. This gives $b=\frac{5}{16}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0\\
\alpha_\infty^+ &= \frac{1}{2}+\sqrt{1+4b}=\frac{5}{4}\\
\alpha_\infty^- &= \frac{1}{2}-\sqrt{1+4b}=-\frac{1}{4}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r=\frac{5x^2-2x+5}{4\left(2x^2+x+1\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
$-\frac{1}{4}+\frac{i\sqrt{7}}{4}$	2	0	$\frac{1}{2}+\frac{3\sqrt{42+14i\sqrt{7}}}{56}$	$\frac{1}{2}-\frac{3\sqrt{42+14i\sqrt{7}}}{56}$
$-\frac{1}{4}-\frac{i\sqrt{7}}{4}$	2	0	$\frac{1}{2}+\frac{3\sqrt{42-14i\sqrt{7}}}{56}$	$\frac{1}{2}-\frac{3\sqrt{42-14i\sqrt{7}}}{56}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{5}{4}$	$-\frac{1}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+=\frac{5}{4}$ then

$$\begin{aligned}
d &= \alpha_\infty^+-\left(\alpha_{c_1}^-+\alpha_{c_2}^-\right)\\
&= \frac{5}{4}-\left(\frac{1}{4}\right)\\
&= 1
\end{aligned}$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$\omega=\sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c+\frac{\alpha_c^{s(c)}}{x-c}\right)+s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{-}}{x-c_2}\right) + (+)[\sqrt{r}]_{\infty} \\
&= \frac{\frac{1}{2}-\frac{3\sqrt{42+14i\sqrt{7}}}{56}}{x+\frac{1}{4}-\frac{i\sqrt{7}}{4}} + \frac{\frac{1}{2}-\frac{3\sqrt{42-14i\sqrt{7}}}{56}}{x+\frac{1}{4}+\frac{i\sqrt{7}}{4}} + (0) \\
&= \frac{\frac{1}{2}-\frac{3\sqrt{42+14i\sqrt{7}}}{56}}{x+\frac{1}{4}-\frac{i\sqrt{7}}{4}} + \frac{\frac{1}{2}-\frac{3\sqrt{42-14i\sqrt{7}}}{56}}{x+\frac{1}{4}+\frac{i\sqrt{7}}{4}} \\
&= \frac{x+1}{4x^2+2x+2}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{\frac{1}{2}-\frac{3\sqrt{42+14i\sqrt{7}}}{56}}{x+\frac{1}{4}-\frac{i\sqrt{7}}{4}} + \frac{\frac{1}{2}-\frac{3\sqrt{42-14i\sqrt{7}}}{56}}{x+\frac{1}{4}+\frac{i\sqrt{7}}{4}}\right)(1) + \left(\left(-\frac{\frac{1}{2}-\frac{3\sqrt{42+14i\sqrt{7}}}{56}}{\left(x+\frac{1}{4}-\frac{i\sqrt{7}}{4}\right)^2} - \frac{\frac{1}{2}-\frac{3\sqrt{42-14i\sqrt{7}}}{56}}{\left(x+\frac{1}{4}+\frac{i\sqrt{7}}{4}\right)^2}\right) + \left(\frac{\frac{1}{2}-3\sqrt{}}{x+\frac{1}{4}}\right.\right.$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 1\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x + 1$$

Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx} \\
&= (x+1)\, e^{\int \left(\frac{\frac{1}{2}-\frac{3\sqrt{42+14i\sqrt{7}}}{56}}{x+\frac{1}{4}-\frac{i\sqrt{7}}{4}} + \frac{\frac{1}{2}-\frac{3\sqrt{42-14i\sqrt{7}}}{56}}{x+\frac{1}{4}+\frac{i\sqrt{7}}{4}}\right) dx} \\
&= (x+1)\, e^{\frac{\ln\left(16x^2+8x+8\right)}{8} + \frac{3\sqrt{7}\, \arctan\left(\frac{(4x+1)\sqrt{7}}{7}\right)}{28}} \\
&= (x+1)\, 2^{3/8} \left(2x^2+x+1\right)^{1/8} e^{\frac{3\sqrt{7}\, \arctan\left(\frac{(4x+1)\sqrt{7}}{7}\right)}{28}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{1+7x}{2x^2+x+1}\, dx} \\
&= z_1 e^{-\frac{7\ln\left(2x^2+x+1\right)}{8} + \frac{3\sqrt{7}\, \arctan\left(\frac{(4x+1)\sqrt{7}}{7}\right)}{28}} \\
&= z_1 \left(\frac{e^{\frac{3\sqrt{7}\, \arctan\left(\frac{(4x+1)\sqrt{7}}{7}\right)}{28}}}{\left(2x^2+x+1\right)^{7/8}}\right)
\end{aligned}
$$

Which simplifies to

$$y_1 = \frac{\mathrm{e}^{\frac{3\sqrt{7}\, \arctan\left(\frac{(4x+1)\sqrt{7}}{7}\right)}{14}} (x+1)\, 2^{3/8}}{(2x^2+x+1)^{3/4}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{1+7x}{2x^2+x+1}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-\frac{7\ln(2x^2+x+1)}{4}+\frac{3\sqrt{7}\, \arctan\left(\frac{(4x+1)\sqrt{7}}{7}\right)}{14}}}{(y_1)^2}\, dx \\
&= y_1 \left(\int \frac{\mathrm{e}^{-\frac{7\ln(2x^2+x+1)}{4}+\frac{3\sqrt{7}\, \arctan\left(\frac{(4x+1)\sqrt{7}}{7}\right)}{14}} (2x^2+x+1)^{3/2}\, \mathrm{e}^{-\frac{3\sqrt{7}\, \arctan\left(\frac{(4x+1)\sqrt{7}}{7}\right)}{7}}\, 2^{1/4}}{2(x+1)^2} dx\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{\mathrm{e}^{\frac{3\sqrt{7}\, \arctan\left(\frac{(4x+1)\sqrt{7}}{7}\right)}{14}} (x+1)\, 2^{3/8}}{(2x^2+x+1)^{3/4}}\right) \\
&+ c_2 \left(\frac{\mathrm{e}^{\frac{3\sqrt{7}\, \arctan\left(\frac{(4x+1)\sqrt{7}}{7}\right)}{14}} (x+1)\, 2^{3/8}}{(2x^2+x+1)^{3/4}} \left(\int \frac{\mathrm{e}^{-\frac{7\ln(2x^2+x+1)}{4}+\frac{3\sqrt{7}\, \arctan\left(\frac{(4x+1)\sqrt{7}}{7}\right)}{14}} (2x^2+x+1)^{3/2}\, \mathrm{e}^{-\frac{3\sqrt{7}\, \arctan\left(\frac{(4x+1)}{7}\right.}{7}}}{2(x+1)^2}\right.\right.
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$(2x^2+x+1)\left(\frac{d^2}{dx^2}y(x)\right) + (1+7x)\left(\frac{d}{dx}y(x)\right) + 2y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{2y(x)}{2x^2+x+1} - \frac{(1+7x)\left(\frac{d}{dx}y(x)\right)}{2x^2+x+1}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x) + \frac{(1+7x)\left(\frac{d}{dx}y(x)\right)}{2x^2+x+1} + \frac{2y(x)}{2x^2+x+1} = 0$

☐ Check to see if x_0 is a regular singular point

  - Define functions

    $\left[P_2(x) = \frac{1+7x}{2x^2+x+1}, P_3(x) = \frac{2}{2x^2+x+1}\right]$

  - $\left(\frac{\mathrm{I}\sqrt{7}}{4} + x + \frac{1}{4}\right) \cdot P_2(x)$ is analytic at $x = -\frac{1}{4} - \frac{\mathrm{I}\sqrt{7}}{4}$

$$\left(\left(\frac{I\sqrt{7}}{4}+x+\frac{1}{4}\right)\cdot P_2(x)\right)\Big|_{x=-\frac{1}{4}-\frac{I\sqrt{7}}{4}}=0$$

- $\left(\frac{I\sqrt{7}}{4}+x+\frac{1}{4}\right)^2\cdot P_3(x)$ is analytic at $x=-\frac{1}{4}-\frac{I\sqrt{7}}{4}$

$$\left(\left(\frac{I\sqrt{7}}{4}+x+\frac{1}{4}\right)^2\cdot P_3(x)\right)\Big|_{x=-\frac{1}{4}-\frac{I\sqrt{7}}{4}}=0$$

- $x=-\frac{1}{4}-\frac{I\sqrt{7}}{4}$is a regular singular point

Check to see if x_0 is a regular singular point

$x_0=-\frac{1}{4}-\frac{I\sqrt{7}}{4}$

- Multiply by denominators

$$(2x^2+x+1)\left(\frac{d^2}{dx^2}y(x)\right)+(1+7x)\left(\frac{d}{dx}y(x)\right)+2y(x)=0$$

- Change variables using $x=u-\frac{1}{4}-\frac{I\sqrt{7}}{4}$ so that the regular singular point is at $u=0$

$$(2u^2-Iu\sqrt{7})\left(\frac{d^2}{du^2}y(u)\right)+\left(-\frac{3}{4}+7u-\frac{7I\sqrt{7}}{4}\right)\left(\frac{d}{du}y(u)\right)+2y(u)=0$$

- Assume series solution for $y(u)$

$$y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$$

☐ Rewrite ODE with series expansions

- Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$

$$u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,u^{k+r-1+m}$$

- Shift index using $k->k+1-m$

$$u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,u^{k+r}$$

- Convert $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m=1..2$

$$u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)(k+r-1)\,u^{k+r-2+m}$$

- Shift index using $k->k+2-m$

$$u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=-2+m}^{\infty}a_{k+2-m}(k+2-m+r)(k+1-m+r)\,u^{k+r}$$

Rewrite ODE with series expansions

$$\frac{I\sqrt{7}\left(3I\sqrt{7}-21-28r\right)ra_0u^{-1+r}}{28}+\left(\sum_{k=0}^{\infty}\left(\frac{I\sqrt{7}\left(3I\sqrt{7}-28k-49-28r\right)(k+1+r)a_{k+1}}{28}+a_k(k+r+2)(2k+2r+1)\right)\right)$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$\frac{I}{28}\sqrt{7}\left(3I\sqrt{7}-21-28r\right)r=0$$

- Values of r that satisfy the indicial equation

$$r\in\left\{0,\frac{3I\sqrt{7}}{28}-\frac{3}{4}\right\}$$

- Each term in the series must be 0, giving the recursion relation

$$-Ia_{k+1}(k+1+r)\left(k+r+\frac{7}{4}\right)\sqrt{7}+\frac{(-3k-3r-3)a_{k+1}}{4}+2(k+r+2)\,a_k\left(k+r+\frac{1}{2}\right)=0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1}=\frac{4a_k\left(2k^2+4kr+2r^2+5k+5r+2\right)}{3+4I\sqrt{7}\,k^2+8I\sqrt{7}\,kr+4I\sqrt{7}\,r^2+11I\sqrt{7}\,k+11I\sqrt{7}\,r+7I\sqrt{7}+3k+3r}$$

- Recursion relation for $r=0$

$$a_{k+1}=\frac{4a_k\left(2k^2+5k+2\right)}{3+4I\sqrt{7}\,k^2+11I\sqrt{7}\,k+7I\sqrt{7}+3k}$$

- Solution for $r=0$

$$\left[y(u)=\sum_{k=0}^{\infty}a_k u^k, a_{k+1}=\frac{4a_k\left(2k^2+5k+2\right)}{3+4I\sqrt{7}\,k^2+11I\sqrt{7}\,k+7I\sqrt{7}+3k}\right]$$

- Revert the change of variables $u = \frac{I\sqrt{7}}{4} + x + \frac{1}{4}$

$$\left[y(x) = \sum_{k=0}^{\infty} a_k \left(\frac{I\sqrt{7}}{4} + x + \frac{1}{4}\right)^k, a_{k+1} = \frac{4a_k\,(2k^2+5k+2)}{3+4\,I\sqrt{7}\,k^2+11\,I\sqrt{7}\,k+7\,I\sqrt{7}+3k}\right]$$

- Recursion relation for $r = \frac{3\,I\sqrt{7}}{28} - \frac{3}{4}$

$$a_{k+1} = \frac{4a_k\left(2k^2+4k\left(\frac{3\,I\sqrt{7}}{28}-\frac{3}{4}\right)+2\left(\frac{3\,I\sqrt{7}}{28}-\frac{3}{4}\right)^2+5k+\frac{15\,I\sqrt{7}}{28}-\frac{7}{4}\right)}{\frac{3}{4}+4\,I\sqrt{7}\,k^2+8\,I\sqrt{7}\,k\left(\frac{3\,I\sqrt{7}}{28}-\frac{3}{4}\right)+4\,I\sqrt{7}\left(\frac{3\,I\sqrt{7}}{28}-\frac{3}{4}\right)^2+11\,I\sqrt{7}\,k+11\,I\sqrt{7}\left(\frac{3\,I\sqrt{7}}{28}-\frac{3}{4}\right)+\frac{205\,I\sqrt{7}}{28}+3k}$$

- Solution for $r = \frac{3\,I\sqrt{7}}{28} - \frac{3}{4}$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+\frac{3\,I\sqrt{7}}{28}-\frac{3}{4}}, a_{k+1} = \frac{4a_k\left(2k^2+4k\left(\frac{3\,I\sqrt{7}}{28}-\frac{3}{4}\right)+2\left(\frac{3\,I\sqrt{7}}{28}-\frac{3}{4}\right)^2+5k+\frac{15\,I\sqrt{7}}{28}-\frac{7}{4}\right)}{\frac{3}{4}+4\,I\sqrt{7}\,k^2+8\,I\sqrt{7}\,k\left(\frac{3\,I\sqrt{7}}{28}-\frac{3}{4}\right)+4\,I\sqrt{7}\left(\frac{3\,I\sqrt{7}}{28}-\frac{3}{4}\right)^2+11\,I\sqrt{7}\,k+11\,I\sqrt{7}\left(\frac{3\,I\sqrt{7}}{28}-\frac{3}{4}\right)+\frac{205\,I}{28}}$$

- Revert the change of variables $u = \frac{I\sqrt{7}}{4} + x + \frac{1}{4}$

$$\left[y(x) = \sum_{k=0}^{\infty} a_k \left(\frac{I\sqrt{7}}{4} + x + \frac{1}{4}\right)^{k+\frac{3\,I\sqrt{7}}{28}-\frac{3}{4}}, a_{k+1} = \frac{4a_k\left(2k^2+4k\left(\frac{3\,I\sqrt{7}}{28}-\frac{3}{4}\right)+2\left(\frac{3\,I\sqrt{7}}{28}-\frac{3}{4}\right)^2+5k+\frac{15\,I\sqrt{}}{28}\right.}{\frac{3}{4}+4\,I\sqrt{7}\,k^2+8\,I\sqrt{7}\,k\left(\frac{3\,I\sqrt{7}}{28}-\frac{3}{4}\right)+4\,I\sqrt{7}\left(\frac{3\,I\sqrt{7}}{28}-\frac{3}{4}\right)^2+11\,I\sqrt{7}\,k+11\,I\sqrt{7}}$$

- Combine solutions and rename parameters

$$\left[y(x) = \left(\sum_{k=0}^{\infty} a_k \left(\frac{I\sqrt{7}}{4} + x + \frac{1}{4}\right)^k\right) + \left(\sum_{k=0}^{\infty} b_k \left(\frac{I\sqrt{7}}{4} + x + \frac{1}{4}\right)^{k+\frac{3\,I\sqrt{7}}{28}-\frac{3}{4}}\right), a_{k+1} = \frac{4a_k\,(2k^2+5k+2)}{3+4\,I\sqrt{7}\,k^2+11\,I\sqrt{7}\,k+7\,I\sqrt{}}\right.$$

2.1.75 Problem 77

Internal problem ID [9247]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 77
Date solved : `Monday, January 27, 2025 at 06:00:30 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$(3+x)\,y''+(1+2x)\,y'-(2-x)\,y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.161 (sec)

Writing the ode as

$$(3+x)\,y''+(1+2x)\,y'+(x-2)\,y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=3+x\\B&=1+2x\\C&=x-2\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned}r&=\frac{s}{t}\\&=\frac{2AB'-2BA'+B^2-4AC}{4A^2}\end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{35}{4\,(3+x)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned}s&=35\\t&=4(3+x)^2\end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{35}{4\,(3+x)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.134: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(3+x)^2$. There is a pole at $x = -3$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{35}{4\,(3+x)^2}$$

For the pole at $x = -3$ let b be the coefficient of $\frac{1}{(3+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{35}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{5}{2} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{35}{4\,(3+x)^2}$$

Since the gcd$(s,t)=1$. This gives $b=\frac{35}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2}+\sqrt{1+4b}=\frac{7}{2} \\
\alpha_\infty^- &= \frac{1}{2}-\sqrt{1+4b}=-\frac{5}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r=\frac{35}{4\,(3+x)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
-3	2	0	$\frac{7}{2}$	$-\frac{5}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{7}{2}$	$-\frac{5}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^-=-\frac{5}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\
&= -\frac{5}{2}-\left(-\frac{5}{2}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$
\omega=\sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c+\frac{\alpha_c^{s(c)}}{x-c}\right)+s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1}+\frac{\alpha_{c_1}^-}{x-c_1}\right)+(-)[\sqrt{r}]_\infty \\
&= -\frac{5}{2\,(3+x)}+(-)\,(0) \\
&= -\frac{5}{2\,(3+x)} \\
&= -\frac{5}{2\,(3+x)}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p''+2\omega p'+\left(\omega'+\omega^2-r\right)p=0 \tag{1A}
$$

Let

$$
p(x)=1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(-\frac{5}{2\left(3+x\right)}\right)(0)+\left(\left(\frac{5}{2\left(3+x\right)^{2}}\right)+\left(-\frac{5}{2\left(3+x\right)}\right)^{2}-\left(\frac{35}{4\left(3+x\right)^{2}}\right)\right)=0$$
$$0=0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z''=rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= \mathrm{e}^{\int -\frac{5}{2(3+x)}dx} \\ &= \frac{1}{\left(3+x\right)^{5/2}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{1+2x}{3+x}\,dx} \\ &= z_1 e^{-x+\frac{5\ln(3+x)}{2}} \\ &= z_1\left(\left(3+x\right)^{5/2}\mathrm{e}^{-x}\right) \end{aligned}$$

Which simplifies to

$$y_1=\mathrm{e}^{-x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{1+2x}{3+x}\,dx}}{\left(y_1\right)^2}\,dx \\ &= y_1 \int \frac{e^{-2x+5\ln(3+x)}}{\left(y_1\right)^2}\,dx \\ &= y_1\left(\frac{x\left(x^5+18x^4+135x^3+540x^2+1215x+1458\right)\mathrm{e}^{-2x+5\ln(3+x)}\mathrm{e}^{2x}}{6\left(3+x\right)^5}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\mathrm{e}^{-x}\right)+c_2\left(\mathrm{e}^{-x}\left(\frac{x\left(x^5+18x^4+135x^3+540x^2+1215x+1458\right)\mathrm{e}^{-2x+5\ln(3+x)}\mathrm{e}^{2x}}{6\left(3+x\right)^5}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$(x+3)\left(\frac{d^2}{dx^2}y(x)\right)+(2x+1)\left(\frac{d}{dx}y(x)\right)-(-x+2)\,y(x)=0$

- Highest derivative means the order of the ODE is 2

$\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

$\frac{d^2}{dx^2}y(x)=-\frac{(x-2)y(x)}{x+3}-\frac{(2x+1)\left(\frac{d}{dx}y(x)\right)}{x+3}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

$\frac{d^2}{dx^2}y(x)+\frac{(2x+1)\left(\frac{d}{dx}y(x)\right)}{x+3}+\frac{(x-2)y(x)}{x+3}=0$

□ Check to see if $x_0=-3$ is a regular singular point

  - Define functions

  $\left[P_2(x)=\frac{2x+1}{x+3}, P_3(x)=\frac{x-2}{x+3}\right]$

  - $(x+3)\cdot P_2(x)$ is analytic at $x=-3$

  $\left((x+3)\cdot P_2(x)\right)\Big|_{x=-3}=-5$

  - $(x+3)^2\cdot P_3(x)$ is analytic at $x=-3$

  $\left((x+3)^2\cdot P_3(x)\right)\Big|_{x=-3}=0$

  - $x=-3$is a regular singular point

Check to see if $x_0=-3$ is a regular singular point

$x_0=-3$

- Multiply by denominators

$(x+3)\left(\frac{d^2}{dx^2}y(x)\right)+(2x+1)\left(\frac{d}{dx}y(x)\right)+(x-2)\,y(x)=0$

- Change variables using $x=u-3$ so that the regular singular point is at $u=0$

$u\left(\frac{d^2}{du^2}y(u)\right)+(2u-5)\left(\frac{d}{du}y(u)\right)+(u-5)\,y(u)=0$

- Assume series solution for $y(u)$

$y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

□ Rewrite ODE with series expansions

  - Convert $u^m\cdot y(u)$ to series expansion for $m=0..1$

  $u^m\cdot y(u)=\sum_{k=0}^{\infty}a_k u^{k+r+m}$

  - Shift index using $k->k-m$

  $u^m\cdot y(u)=\sum_{k=m}^{\infty}a_{k-m}u^{k+r}$

  - Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$

  $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,u^{k+r-1+m}$

  - Shift index using $k->k+1-m$

  $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,u^{k+r}$

  - Convert $u\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion

  $u\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,u^{k+r-1}$

  - Shift index using $k->k+1$

$u \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)(k+r)u^{k+r}$

Rewrite ODE with series expansions

$a_0r(-6+r)u^{-1+r} + (a_1(1+r)(-5+r) + a_0(-5+2r))u^r + \left(\sum_{k=1}^{\infty} (a_{k+1}(k+1+r)(k-5+r)\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $r(-6+r) = 0$
- Values of r that satisfy the indicial equation
  $r \in \{0, 6\}$
- Each term must be 0
  $a_1(1+r)(-5+r) + a_0(-5+2r) = 0$
- Each term in the series must be 0, giving the recursion relation
  $a_{k+1}(k+1+r)(k-5+r) + 2a_kk + 2a_kr - 5a_k + a_{k-1} = 0$
- Shift index using $k- >k+1$
  $a_{k+2}(k+2+r)(k-4+r) + 2a_{k+1}(k+1) + 2ra_{k+1} - 5a_{k+1} + a_k = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+2} = -\frac{2ka_{k+1}+2ra_{k+1}+a_k-3a_{k+1}}{(k+2+r)(k-4+r)}$
- Recursion relation for $r = 0$
  $a_{k+2} = -\frac{2ka_{k+1}+a_k-3a_{k+1}}{(k+2)(k-4)}$
- Series not valid for $r = 0$, division by 0 in the recursion relation at $k = 4$
  $a_{k+2} = -\frac{2ka_{k+1}+a_k-3a_{k+1}}{(k+2)(k-4)}$
- Recursion relation for $r = 6$
  $a_{k+2} = -\frac{2ka_{k+1}+a_k+9a_{k+1}}{(k+8)(k+2)}$
- Solution for $r = 6$
  $\left[y(u) = \sum_{k=0}^{\infty} a_ku^{k+6}, a_{k+2} = -\frac{2ka_{k+1}+a_k+9a_{k+1}}{(k+8)(k+2)}, 7a_1 + 7a_0 = 0\right]$
- Revert the change of variables $u = x+3$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k(x+3)^{k+6}, a_{k+2} = -\frac{2ka_{k+1}+a_k+9a_{k+1}}{(k+8)(k+2)}, 7a_1 + 7a_0 = 0\right]$

CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$y'' + 3xy' + \left(2x^2 + 4\right) y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.242 (sec)

Writing the ode as

$$y'' + 3xy' + \left(2x^2 + 4\right) y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 3x \\ C &= 2x^2 + 4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 - 10}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2 - 10 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2}{4} - \frac{5}{2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.136: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 2 \\ &= -2 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x}{2} - \frac{5}{2x} - \frac{25}{4x^3} - \frac{125}{4x^5} - \frac{3125}{16x^7} - \frac{21875}{16x^9} - \frac{328125}{32x^{11}} - \frac{2578125}{32x^{13}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= \frac{x}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{x^2}{4}$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 - 10}{4} \\ &= Q + \frac{R}{4} \\ &= \left(\frac{x^2}{4} - \frac{5}{2}\right) + (0) \\ &= \frac{x^2}{4} - \frac{5}{2} \end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is $-\frac{5}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{5}{2}\right) - (0) \\ &= -\frac{5}{2} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{x}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{5}{2}}{\frac{1}{2}} - 1\right) &&= -3 \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{5}{2}}{\frac{1}{2}} - 1\right) &&= 2 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2}{4} - \frac{5}{2}$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-2	$\frac{x}{2}$	-3	2

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either + or − and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 2$, and since there are no poles then

$$\begin{aligned} d &= \alpha_\infty^- \\ &= 2 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= (-)[\sqrt{r}]_\infty \\ &= 0 + (-)\left(\frac{x}{2}\right) \\ &= -\frac{x}{2} \\ &= -\frac{x}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 2$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}$$

Let

$$p(x) = x^2 + a_1 x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (2) + 2\left(-\frac{x}{2}\right)(2x + a_1) + \left(\left(-\frac{1}{2}\right) + \left(-\frac{x}{2}\right)^2 - \left(\frac{x^2}{4} - \frac{5}{2}\right)\right) &= 0 \\ a_1 x + 2a_0 + 2 &= 0 \end{aligned}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = -1, a_1 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^2 - 1$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega\, dx} \\ &= \left(x^2 - 1\right) e^{\int -\frac{x}{2} dx} \\ &= \left(x^2 - 1\right) e^{-\frac{x^2}{4}} \\ &= \left(x^2 - 1\right) e^{-\frac{x^2}{4}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{3x}{1}\, dx} \\ &= z_1 e^{-\frac{3x^2}{4}} \\ &= z_1\left(e^{-\frac{3x^2}{4}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = (x^2 - 1)\,\mathrm{e}^{-x^2}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{3x}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{3x^2}{2}}}{(y_1)^2}\,dx \\
&= y_1 \left(\int \frac{\mathrm{e}^{-\frac{3x^2}{2}}\,\mathrm{e}^{2x^2}}{(x^2-1)^2} dx\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left((x^2-1)\,\mathrm{e}^{-x^2}\right) + c_2\left((x^2-1)\,\mathrm{e}^{-x^2}\left(\int \frac{\mathrm{e}^{-\frac{3x^2}{2}}\,\mathrm{e}^{2x^2}}{(x^2-1)^2} dx\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$\frac{d^2}{dx^2}y(x) + 3x\left(\frac{d}{dx}y(x)\right) + (2x^2+4)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite ODE with series expansions

  ◦ Convert $x^m \cdot y(x)$ to series expansion for $m = 0..2$

    $x^m \cdot y(x) = \sum_{k=\max(0,-m)}^{\infty} a_k x^{k+m}$

  ◦ Shift index using $k- > k - m$

    $x^m \cdot y(x) = \sum_{k=\max(0,-m)+m}^{\infty} a_{k-m} x^k$

  ◦ Convert $x \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion

    $x \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k k\, x^k$

  ◦ Convert $\frac{d^2}{dx^2}y(x)$ to series expansion

    $\frac{d^2}{dx^2}y(x) = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$

  ◦ Shift index using $k- > k + 2$

$\frac{d^2}{dx^2}y(x) = \sum_{k=0}^{\infty} a_{k+2}(k+2)(k+1)\, x^k$

Rewrite ODE with series expansions

$2a_2 + 4a_0 + (6a_3 + 7a_1)\, x + \left(\sum_{k=2}^{\infty} (a_{k+2}(k+2)(k+1) + a_k(3k+4) + 2a_{k-2})\, x^k\right) = 0$

- The coefficients of each power of x must be 0

  $[2a_2 + 4a_0 = 0, 6a_3 + 7a_1 = 0]$

- Solve for the dependent coefficient(s)

  $\left\{a_2 = -2a_0, a_3 = -\frac{7a_1}{6}\right\}$

- Each term in the series must be 0, giving the recursion relation

  $(k^2 + 3k + 2)\, a_{k+2} + 3a_k k + 4a_k + 2a_{k-2} = 0$

- Shift index using $k- > k+2$

  $\left((k+2)^2 + 3k + 8\right) a_{k+4} + 3a_{k+2}(k+2) + 4a_{k+2} + 2a_k = 0$

- Recursion relation that defines the series solution to the ODE

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^k, a_{k+4} = -\frac{3ka_{k+2}+2a_k+10a_{k+2}}{k^2+7k+12}, a_2 = -2a_0, a_3 = -\frac{7a_1}{6}\right]$

CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$(2+4x)\, y''-4y'-(6+4x)\, y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.223 (sec)

Writing the ode as

$$(2+4x)\, y''-4y'+(-4x-6)\, y = 0 \tag{1}$$
$$Ay''+By'+Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2+4x \\ B &= -4 \\ C &= -4x-6 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{4x^2+8x+6}{(1+2x)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 4x^2+8x+6 \\ t &= (1+2x)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{4x^2+8x+6}{(1+2x)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.138: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (1 + 2x)^2$. There is a pole at $x = -\frac{1}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = 1 + \frac{3}{4\left(x + \frac{1}{2}\right)^2} + \frac{1}{x + \frac{1}{2}}$$

For the pole at $x = -\frac{1}{2}$ let b be the coefficient of $\frac{1}{\left(x+\frac{1}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx 1 + \frac{1}{2x} - \frac{1}{4x^3} + \frac{11}{32x^4} - \frac{21}{64x^5} + \frac{15}{64x^6} - \frac{3}{32x^7} - \frac{117}{2048x^8} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = 1$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= 1 \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = 1$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{4x^2 + 8x + 6}{4x^2 + 4x + 1} \\ &= Q + \frac{R}{4x^2 + 4x + 1} \\ &= (1) + \left(\frac{4x + 5}{4x^2 + 4x + 1}\right) \\ &= 1 + \frac{4x + 5}{4x^2 + 4x + 1} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is 4. Dividing this by leading coefficient in t which is 4 gives 1. Now b can be found.

$$\begin{aligned} b &= (1) - (0) \\ &= 1 \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= 1 \\ \alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{1}{1} - 0\right) &&= \frac{1}{2} \\ \alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{1}{1} - 0\right) &&= -\frac{1}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{4x^2+8x+6}{(1+2x)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
$-\frac{1}{2}$	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	1	$\frac{1}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -\frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^- - (\alpha_{c_1}^-) \\ &= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= -\frac{1}{2\left(x+\frac{1}{2}\right)} + (-)(1) \\ &= -\frac{1}{2\left(x+\frac{1}{2}\right)} - 1 \\ &= -\frac{2(x+1)}{1+2x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{2\left(x+\frac{1}{2}\right)} - 1\right)(0) + \left(\left(\frac{1}{2\left(x+\frac{1}{2}\right)^2}\right) + \left(-\frac{1}{2\left(x+\frac{1}{2}\right)} - 1\right)^2 - \left(\frac{4x^2+8x+6}{(1+2x)^2}\right)\right) = 0$$

$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= \mathrm{e}^{\int \left(-\frac{1}{2\left(x+\frac{1}{2}\right)}-1\right) dx} \\ &= \frac{\mathrm{e}^{-x}}{\sqrt{1+2x}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-4}{2+4x} \, dx} \\ &= z_1 e^{\frac{\ln(1+2x)}{2}} \\ &= z_1 \left(\sqrt{1+2x}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-4}{2+4x} \, dx}}{(y_1)^2} \, dx \\ &= y_1 \int \frac{e^{\ln(1+2x)}}{(y_1)^2} \, dx \\ &= y_1 \left(x \, \mathrm{e}^{2x}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\mathrm{e}^{-x}\right) + c_2 \left(\mathrm{e}^{-x} \left(x \, \mathrm{e}^{2x}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$(2+4x)\left(\frac{d^2}{dx^2}y(x)\right) - 4\frac{d}{dx}y(x) - (6+4x)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = \frac{(2x+3)y(x)}{2x+1} + \frac{2\left(\frac{d}{dx}y(x)\right)}{2x+1}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

$\frac{d^2}{dx^2}y(x) - \frac{2\left(\frac{d}{dx}y(x)\right)}{2x+1} - \frac{(2x+3)y(x)}{2x+1} = 0$

- ☐ Check to see if $x_0 = -\frac{1}{2}$ is a regular singular point
  - ◦ Define functions
    $\left[P_2(x) = -\frac{2}{2x+1}, P_3(x) = -\frac{2x+3}{2x+1}\right]$
  - ◦ $\left(x+\frac{1}{2}\right)\cdot P_2(x)$ is analytic at $x = -\frac{1}{2}$
    $\left(\left(x+\frac{1}{2}\right)\cdot P_2(x)\right)\Big|_{x=-\frac{1}{2}} = -1$
  - ◦ $\left(x+\frac{1}{2}\right)^2\cdot P_3(x)$ is analytic at $x = -\frac{1}{2}$
    $\left(\left(x+\frac{1}{2}\right)^2\cdot P_3(x)\right)\Big|_{x=-\frac{1}{2}} = 0$
  - ◦ $x = -\frac{1}{2}$is a regular singular point
    Check to see if $x_0 = -\frac{1}{2}$ is a regular singular point
    $x_0 = -\frac{1}{2}$
- • Multiply by denominators
  $(2x+1)\left(\frac{d^2}{dx^2}y(x)\right) - 2\frac{d}{dx}y(x) + (-2x-3)\,y(x) = 0$
- • Change variables using $x = u - \frac{1}{2}$ so that the regular singular point is at $u = 0$
  $2u\left(\frac{d^2}{du^2}y(u)\right) - 2\frac{d}{du}y(u) + (-2u-2)\,y(u) = 0$
- • Assume series solution for $y(u)$
  $y(u) = \sum\limits_{k=0}^{\infty} a_k u^{k+r}$
- ☐ Rewrite ODE with series expansions
  - ◦ Convert $u^m \cdot y(u)$ to series expansion for $m = 0..1$
    $u^m \cdot y(u) = \sum\limits_{k=0}^{\infty} a_k u^{k+r+m}$
  - ◦ Shift index using $k- >k-m$
    $u^m \cdot y(u) = \sum\limits_{k=m}^{\infty} a_{k-m} u^{k+r}$
  - ◦ Convert $\frac{d}{du}y(u)$ to series expansion
    $\frac{d}{du}y(u) = \sum\limits_{k=0}^{\infty} a_k(k+r)\,u^{k+r-1}$
  - ◦ Shift index using $k- >k+1$
    $\frac{d}{du}y(u) = \sum\limits_{k=-1}^{\infty} a_{k+1}(k+1+r)\,u^{k+r}$
  - ◦ Convert $u\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion
    $u\cdot\left(\frac{d^2}{du^2}y(u)\right) = \sum\limits_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,u^{k+r-1}$
  - ◦ Shift index using $k- >k+1$
    $u\cdot\left(\frac{d^2}{du^2}y(u)\right) = \sum\limits_{k=-1}^{\infty} a_{k+1}(k+1+r)\,(k+r)\,u^{k+r}$
    Rewrite ODE with series expansions
    $2a_0r(-2+r)\,u^{-1+r} + (2a_1(1+r)\,(-1+r) - 2a_0)\,u^r + \left(\sum\limits_{k=1}^{\infty} (2a_{k+1}(k+1+r)\,(k+r-1) - 2a_k\right.$
- • $a_0$cannot be 0 by assumption, giving the indicial equation
  $2r(-2+r) = 0$
- • Values of r that satisfy the indicial equation
  $r \in \{0, 2\}$

- Each term must be 0
  $2a_1(1+r)(-1+r) - 2a_0 = 0$
- Each term in the series must be 0, giving the recursion relation
  $2a_{k+1}(k+1+r)(k+r-1) - 2a_k - 2a_{k-1} = 0$
- Shift index using $k- > k+1$
  $2a_{k+2}(k+2+r)(k+r) - 2a_{k+1} - 2a_k = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+2} = \frac{a_{k+1}+a_k}{(k+2+r)(k+r)}$
- Recursion relation for $r = 0$
  $a_{k+2} = \frac{a_{k+1}+a_k}{(k+2)k}$
- Series not valid for $r = 0$, division by 0 in the recursion relation at $k = 0$
  $a_{k+2} = \frac{a_{k+1}+a_k}{(k+2)k}$
- Recursion relation for $r = 2$
  $a_{k+2} = \frac{a_{k+1}+a_k}{(k+4)(k+2)}$
- Solution for $r = 2$
  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+2}, a_{k+2} = \frac{a_{k+1}+a_k}{(k+4)(k+2)}, 6a_1 - 2a_0 = 0\right]$
- Revert the change of variables $u = x + \frac{1}{2}$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k \left(x+\frac{1}{2}\right)^{k+2}, a_{k+2} = \frac{a_{k+1}+a_k}{(k+4)(k+2)}, 6a_1 - 2a_0 = 0\right]$

2.1.78 Problem 80

Internal problem ID [9250]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 80
Date solved : `Monday, January 27, 2025 at 06:00:32 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$y'' - 3xy' + (2x^2 + 5)\, y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.231 (sec)

Writing the ode as

$$y'' - 3xy' + (2x^2 + 5)\, y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -3x \\ C &= 2x^2 + 5 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 - 26}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2 - 26 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2}{4} - \frac{13}{2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.140: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 2 \\ &= -2 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x}{2} - \frac{13}{2x} - \frac{169}{4x^3} - \frac{2197}{4x^5} - \frac{142805}{16x^7} - \frac{2599051}{16x^9} - \frac{101362989}{32x^{11}} - \frac{2070701061}{32x^{13}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= \frac{x}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{x^2}{4}$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 - 26}{4} \\ &= Q + \frac{R}{4} \\ &= \left(\frac{x^2}{4} - \frac{13}{2}\right) + (0) \\ &= \frac{x^2}{4} - \frac{13}{2} \end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is $-\frac{13}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{13}{2}\right) - (0) \\ &= -\frac{13}{2} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{x}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{13}{2}}{\frac{1}{2}} - 1\right) &&= -7 \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{13}{2}}{\frac{1}{2}} - 1\right) &&= 6 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2}{4} - \frac{13}{2}$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-2	$\frac{x}{2}$	-7	6

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 6$, and since there are no poles then

$$\begin{aligned} d &= \alpha_\infty^- \\ &= 6 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= (-)[\sqrt{r}]_\infty \\ &= 0 + (-)\left(\frac{x}{2}\right) \\ &= -\frac{x}{2} \\ &= -\frac{x}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 6$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}$$

Let

$$p(x) = x^6 + a_5x^5 + a_4x^4 + a_3x^3 + a_2x^2 + a_1x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\left(30x^4 + 20x^3a_5 + 12x^2a_4 + 6xa_3 + 2a_2\right) + 2\left(-\frac{x}{2}\right)\left(6x^5 + 5x^4a_5 + 4x^3a_4 + 3x^2a_3 + 2xa_2 + a_1\right) + \left(\left(-\frac{1}{2}\right.\right.$$

$$a_5x^5 + 2(15 + a_4)x^4 + (3a_3 + 20a_5)x^3 + 4(a_2 + 3a_4)x^2 + (5$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = -15, a_1 = 0, a_2 = 45, a_3 = 0, a_4 = -15, a_5 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^6 - 15x^4 + 45x^2 - 15$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= pe^{\int \omega\, dx} \\ &= \left(x^6 - 15x^4 + 45x^2 - 15\right)e^{\int -\frac{x}{2} dx} \\ &= \left(x^6 - 15x^4 + 45x^2 - 15\right)e^{-\frac{x^2}{4}} \\ &= \left(x^6 - 15x^4 + 45x^2 - 15\right)e^{-\frac{x^2}{4}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-3x}{1}\, dx} \\ &= z_1 e^{\frac{3x^2}{4}} \\ &= z_1\left(e^{\frac{3x^2}{4}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = e^{\frac{x^2}{2}}\left(x^6 - 15x^4 + 45x^2 - 15\right)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-3x}{1}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{\frac{3x^2}{2}}}{(y_1)^2}\, dx \\ &= y_1 \left(\int \frac{e^{\frac{3x^2}{2}} e^{-x^2}}{\left(x^6 - 15x^4 + 45x^2 - 15\right)^2} dx\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(e^{\frac{x^2}{2}}\left(x^6 - 15x^4 + 45x^2 - 15\right)\right) \\ &\quad + c_2\left(e^{\frac{x^2}{2}}\left(x^6 - 15x^4 + 45x^2 - 15\right)\left(\int \frac{e^{\frac{3x^2}{2}} e^{-x^2}}{\left(x^6 - 15x^4 + 45x^2 - 15\right)^2} dx\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$\frac{d^2}{dx^2}y(x) - 3x\left(\frac{d}{dx}y(x)\right) + \left(2x^2 + 5\right) y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite ODE with series expansions

  ◦ Convert $x^m \cdot y(x)$ to series expansion for $m = 0..2$

  $x^m \cdot y(x) = \sum_{k=\max(0,-m)}^{\infty} a_k x^{k+m}$

  ◦ Shift index using $k- > k - m$

  $x^m \cdot y(x) = \sum_{k=\max(0,-m)+m}^{\infty} a_{k-m} x^k$

  ◦ Convert $x \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion

  $x \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k k\, x^k$

  ◦ Convert $\frac{d^2}{dx^2}y(x)$ to series expansion

  $\frac{d^2}{dx^2}y(x) = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$

- Shift index using $k->k+2$

  $\frac{d^2}{dx^2}y(x)=\sum_{k=0}^{\infty} a_{k+2}(k+2)(k+1)x^k$

  Rewrite ODE with series expansions

  $2a_2+5a_0+(6a_3+2a_1)x+\left(\sum_{k=2}^{\infty}(a_{k+2}(k+2)(k+1)-a_k(3k-5)+2a_{k-2})x^k\right)=0$

- The coefficients of each power of x must be 0

  $[2a_2+5a_0=0, 6a_3+2a_1=0]$

- Solve for the dependent coefficient(s)

  $\left\{a_2=-\frac{5a_0}{2}, a_3=-\frac{a_1}{3}\right\}$

- Each term in the series must be 0, giving the recursion relation

  $(k^2+3k+2)a_{k+2}-3a_kk+5a_k+2a_{k-2}=0$

- Shift index using $k->k+2$

  $\left((k+2)^2+3k+8\right)a_{k+4}-3a_{k+2}(k+2)+5a_{k+2}+2a_k=0$

- Recursion relation that defines the series solution to the ODE

  $\left[y(x)=\sum_{k=0}^{\infty}a_kx^k, a_{k+4}=\frac{3ka_{k+2}-2a_k+a_{k+2}}{k^2+7k+12}, a_2=-\frac{5a_0}{2}, a_3=-\frac{a_1}{3}\right]$

2.1.79 Problem 81

Internal problem ID [9251]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 81
Date solved : `Monday, January 27, 2025 at 06:00:33 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$2y'' + 5xy' + \left(2x^2 + 4\right) y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.187 (sec)

Writing the ode as

$$2y'' + 5xy' + \left(2x^2 + 4\right) y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2 \\ B &= 5x \\ C &= 2x^2 + 4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{9x^2 - 12}{16} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 9x^2 - 12 \\ t &= 16 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{9x^2}{16} - \frac{3}{4}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.142: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 2 \\ &= -2 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{3x}{4} - \frac{1}{2x} - \frac{1}{6x^3} - \frac{1}{9x^5} - \frac{5}{54x^7} - \frac{7}{81x^9} - \frac{7}{81x^{11}} - \frac{22}{243x^{13}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{3}{4}$$

From Eq. (9) the sum up to $v = 1$ gives

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\
&= \frac{3x}{4}
\end{aligned} \tag{10}
$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{9x^2}{16}$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{9x^2 - 12}{16} \\
&= Q + \frac{R}{16} \\
&= \left(\frac{9x^2}{16} - \frac{3}{4}\right) + (0) \\
&= \frac{9x^2}{16} - \frac{3}{4}
\end{aligned}
$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is $-\frac{3}{4}$. Now b can be found.

$$
\begin{aligned}
b &= \left(-\frac{3}{4}\right) - (0) \\
&= -\frac{3}{4}
\end{aligned}
$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \frac{3x}{4} \\
\alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{3}{4}}{\frac{3}{4}} - 1\right) &&= -1 \\
\alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{3}{4}}{\frac{3}{4}} - 1\right) &&= 0
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{9x^2}{16} - \frac{3}{4}$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
-2	$\frac{3x}{4}$	-1	0

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 0$, and since there are no poles then

$$
\begin{aligned}
d &= \alpha_\infty^- \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= (-)[\sqrt{r}]_\infty \\
&= 0 + (-)\left(\frac{3x}{4}\right) \\
&= -\frac{3x}{4} \\
&= -\frac{3x}{4}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
\begin{aligned}
(0) + 2\left(-\frac{3x}{4}\right)(0) + \left(\left(-\frac{3}{4}\right) + \left(-\frac{3x}{4}\right)^2 - \left(\frac{9x^2}{16} - \frac{3}{4}\right)\right) &= 0 \\
0 &= 0
\end{aligned}
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= e^{\int -\frac{3x}{4} dx} \\
&= e^{-\frac{3x^2}{8}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{5x}{2}\, dx} \\
&= z_1 e^{-\frac{5x^2}{8}} \\
&= z_1 \left(e^{-\frac{5x^2}{8}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = e^{-x^2}
$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{5x}{2}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-\frac{5x^2}{4}}}{(y_1)^2}\, dx \\ &= y_1 \left(-\frac{i\sqrt{\pi}\,\sqrt{3}\,\operatorname{erf}\left(\frac{i\sqrt{3}\,x}{2}\right)}{3}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\mathrm{e}^{-x^2}\right) + c_2 \left(\mathrm{e}^{-x^2} \left(-\frac{i\sqrt{\pi}\,\sqrt{3}\,\operatorname{erf}\left(\frac{i\sqrt{3}\,x}{2}\right)}{3}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$2\frac{d^2}{dx^2}y(x) + 5x\left(\frac{d}{dx}y(x)\right) + (2x^2+4)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = (-x^2-2)\,y(x) - \frac{5x\left(\frac{d}{dx}y(x)\right)}{2}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x) + \frac{5x\left(\frac{d}{dx}y(x)\right)}{2} + (x^2+2)\,y(x) = 0$

- Multiply by denominators

  $2\frac{d^2}{dx^2}y(x) + 5x\left(\frac{d}{dx}y(x)\right) + (2x^2+4)\,y(x) = 0$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite ODE with series expansions

  ○ Convert $x^m \cdot y(x)$ to series expansion for $m = 0..2$

  $x^m \cdot y(x) = \sum_{k=\max(0,-m)}^{\infty} a_k x^{k+m}$

  ○ Shift index using $k->k-m$

  $x^m \cdot y(x) = \sum_{k=\max(0,-m)+m}^{\infty} a_{k-m} x^k$

  ○ Convert $x \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion

  $x \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k k\, x^k$

- Convert $\frac{d^2}{dx^2}y(x)$ to series expansion

  $\frac{d^2}{dx^2}y(x) = \sum\limits_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$
- Shift index using $k- > k+2$

  $\frac{d^2}{dx^2}y(x) = \sum\limits_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$

  Rewrite ODE with series expansions

  $4a_2 + 4a_0 + (12a_3 + 9a_1)\, x + \left(\sum\limits_{k=2}^{\infty} (2a_{k+2}(k+2)\,(k+1) + a_k(5k+4) + 2a_{k-2})\, x^k\right) = 0$

- The coefficients of each power of x must be 0

  $[4a_2 + 4a_0 = 0, 12a_3 + 9a_1 = 0]$
- Solve for the dependent coefficient(s)

  $\left\{a_2 = -a_0, a_3 = -\frac{3a_1}{4}\right\}$
- Each term in the series must be 0, giving the recursion relation

  $(2k^2 + 6k + 4)\, a_{k+2} + 5a_k k + 4a_k + 2a_{k-2} = 0$
- Shift index using $k- > k+2$

  $\left(2(k+2)^2 + 6k + 16\right) a_{k+4} + 5a_{k+2}(k+2) + 4a_{k+2} + 2a_k = 0$
- Recursion relation that defines the series solution to the ODE

  $\left[y(x) = \sum\limits_{k=0}^{\infty} a_k x^k, a_{k+4} = -\frac{5ka_{k+2}+2a_k+14a_{k+2}}{2(k^2+7k+12)}, a_2 = -a_0, a_3 = -\frac{3a_1}{4}\right]$

2.1.80 Problem 82

Internal problem ID [9252]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 82
Date solved : `Monday, January 27, 2025 at 06:00:33 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$y'' + 4xy' + \left(4x^2 + 2\right) y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.054 (sec)

Writing the ode as

$$y'' + 4xy' + \left(4x^2 + 2\right) y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 4x \\ C &= 4x^2 + 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.144: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{4x}{1}\, dx} \\ &= z_1 e^{-x^2} \\ &= z_1 \left(\mathrm{e}^{-x^2}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-x^2}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{4x}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-2x^2}}{(y_1)^2}\,dx \\
&= y_1(x)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{-x^2}\right) + c_2\left(\mathrm{e}^{-x^2}(x)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

2.1.81 Problem 83

Internal problem ID [9253]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 83
Date solved : `Monday, January 27, 2025 at 06:00:34 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$y'' + 4xy' + \left(4x^2 + 2\right) y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.061 (sec)

Writing the ode as

$$y'' + 4xy' + \left(4x^2 + 2\right) y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 4x \\ C &= 4x^2 + 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\,e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.146: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{4x}{1}\,dx} \\ &= z_1 e^{-x^2} \\ &= z_1\left(\mathrm{e}^{-x^2}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-x^2}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{4x}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-2x^2}}{(y_1)^2}\,dx \\
&= y_1(x)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{-x^2}\right) + c_2\left(\mathrm{e}^{-x^2}(x)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve
$\frac{d^2}{dx^2}y(x) + 4x\left(\frac{d}{dx}y(x)\right) + (4x^2+2)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2
  $\frac{d^2}{dx^2}y(x)$
- Assume series solution for $y(x)$
  $y(x) = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite ODE with series expansions

  ○ Convert $x^m \cdot y(x)$ to series expansion for $m = 0..2$
  $x^m \cdot y(x) = \sum_{k=\max(0,-m)}^{\infty} a_k x^{k+m}$
  ○ Shift index using $k- >k-m$
  $x^m \cdot y(x) = \sum_{k=\max(0,-m)+m}^{\infty} a_{k-m} x^k$
  ○ Convert $x \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion
  $x \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k k\, x^k$
  ○ Convert $\frac{d^2}{dx^2}y(x)$ to series expansion
  $\frac{d^2}{dx^2}y(x) = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$
  ○ Shift index using $k- >k+2$
  $\frac{d^2}{dx^2}y(x) = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$

Rewrite ODE with series expansions
$2a_2 + 2a_0 + (6a_3 + 6a_1)\,x + \left(\sum_{k=2}^{\infty} \left(a_{k+2}(k+2)\,(k+1) + 2a_k(2k+1) + 4a_{k-2}\right) x^k\right) = 0$

- The coefficients of each power of x must be 0
  $[2a_2 + 2a_0 = 0, 6a_3 + 6a_1 = 0]$
- Solve for the dependent coefficient(s)
  $\{a_2 = -a_0, a_3 = -a_1\}$
- Each term in the series must be 0, giving the recursion relation
  $(k^2 + 3k + 2)\,a_{k+2} + 4a_k k + 2a_k + 4a_{k-2} = 0$

- Shift index using $k->k+2$

  $$\left((k+2)^2+3k+8\right)a_{k+4}+4a_{k+2}(k+2)+2a_{k+2}+4a_k=0$$

- Recursion relation that defines the series solution to the ODE

  $$\left[y(x)=\sum_{k=0}^{\infty}a_k x^k, a_{k+4}=-\frac{2(2ka_{k+2}+2a_k+5a_{k+2})}{k^2+7k+12}, a_2=-a_0, a_3=-a_1\right]$$

2.1.82 Problem 84

Internal problem ID [9254]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 84
Date solved : `Monday, January 27, 2025 at 06:00:34 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$2x^2\left(x^2+x+1\right)y''+x\left(11x^2+11x+9\right)y'+\left(7x^2+10x+6\right)y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 1.072 (sec)

Writing the ode as

$$\left(2x^4+2x^3+2x^2\right)y''+\left(11x^3+11x^2+9x\right)y'+\left(7x^2+10x+6\right)y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2x^4+2x^3+2x^2 \\ B &= 11x^3+11x^2+9x \\ C &= 7x^2+10x+6 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{21x^4+18x^3+27x^2-2x-3}{16\left(x^3+x^2+x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 21x^4+18x^3+27x^2-2x-3 \\ t &= 16\left(x^3+x^2+x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{21x^4+18x^3+27x^2-2x-3}{16\left(x^3+x^2+x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.148: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 4 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16(x^3 + x^2 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -\frac{1}{2} + \frac{i\sqrt{3}}{2}$ of order 2. There is a pole at $x = -\frac{1}{2} - \frac{i\sqrt{3}}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{3}{16x^2} + \frac{1}{4x} + \frac{-\frac{5}{24} + \frac{i\sqrt{3}}{24}}{\left(x + \frac{1}{2} - \frac{i\sqrt{3}}{2}\right)^2} + \frac{-\frac{5}{24} - \frac{i\sqrt{3}}{24}}{\left(x + \frac{1}{2} + \frac{i\sqrt{3}}{2}\right)^2} + \frac{-\frac{1}{8} - \frac{43i\sqrt{3}}{72}}{x + \frac{1}{2} - \frac{i\sqrt{3}}{2}} + \frac{-\frac{1}{8} + \frac{43i\sqrt{3}}{72}}{x + \frac{1}{2} + \frac{i\sqrt{3}}{2}}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{3}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{4} \end{aligned}$$

For the pole at $x = -\frac{1}{2} + \frac{i\sqrt{3}}{2}$ let b be the coefficient of $\frac{1}{\left(x+\frac{1}{2}-\frac{i\sqrt{3}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{5}{24} + \frac{i\sqrt{3}}{24}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} + \frac{\sqrt{6+6i\sqrt{3}}}{12} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} - \frac{\sqrt{6+6i\sqrt{3}}}{12}
\end{aligned}
$$

For the pole at $x = -\frac{1}{2} - \frac{i\sqrt{3}}{2}$ let b be the coefficient of $\frac{1}{\left(x+\frac{1}{2}+\frac{i\sqrt{3}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{5}{24} - \frac{i\sqrt{3}}{24}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} + \frac{\sqrt{6-6i\sqrt{3}}}{12} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} - \frac{\sqrt{6-6i\sqrt{3}}}{12}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = \frac{21x^4 + 18x^3 + 27x^2 - 2x - 3}{16\left(x^3 + x^2 + x\right)^2}
$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{21}{16}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{4} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{4}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{21x^4 + 18x^3 + 27x^2 - 2x - 3}{16\left(x^3 + x^2 + x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{3}{4}$	$\frac{1}{4}$
$-\frac{1}{2} + \frac{i\sqrt{3}}{2}$	2	0	$\frac{1}{2} + \frac{\sqrt{6+6i\sqrt{3}}}{12}$	$\frac{1}{2} - \frac{\sqrt{6+6i\sqrt{3}}}{12}$
$-\frac{1}{2} - \frac{i\sqrt{3}}{2}$	2	0	$\frac{1}{2} + \frac{\sqrt{6-6i\sqrt{3}}}{12}$	$\frac{1}{2} - \frac{\sqrt{6-6i\sqrt{3}}}{12}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{7}{4}$	$-\frac{3}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying

$\alpha_\infty^+ = \frac{7}{4}$ then

$$\begin{aligned}d &= \alpha_\infty^+ - \left(\alpha_{c1}^- + \alpha_{c2}^+ + \alpha_{c3}^+\right)\\ &= \frac{7}{4} - \left(\frac{7}{4}\right)\\ &= 0\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x-c_2}\right) + \left((+)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^+}{x-c_3}\right) + (+)[\sqrt{r}]_\infty\\ &= \frac{1}{4x} + \frac{\frac{1}{2}+\frac{\sqrt{6+6i\sqrt{3}}}{12}}{x+\frac{1}{2}-\frac{i\sqrt{3}}{2}} + \frac{\frac{1}{2}+\frac{\sqrt{6-6i\sqrt{3}}}{12}}{x+\frac{1}{2}+\frac{i\sqrt{3}}{2}} + (0)\\ &= \frac{1}{4x} + \frac{\frac{1}{2}+\frac{\sqrt{6+6i\sqrt{3}}}{12}}{x+\frac{1}{2}-\frac{i\sqrt{3}}{2}} + \frac{\frac{1}{2}+\frac{\sqrt{6-6i\sqrt{3}}}{12}}{x+\frac{1}{2}+\frac{i\sqrt{3}}{2}}\\ &= \frac{7x^2+3x+1}{4x\,(x^2+x+1)}\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{4x} + \frac{\frac{1}{2}+\frac{\sqrt{6+6i\sqrt{3}}}{12}}{x+\frac{1}{2}-\frac{i\sqrt{3}}{2}} + \frac{\frac{1}{2}+\frac{\sqrt{6-6i\sqrt{3}}}{12}}{x+\frac{1}{2}+\frac{i\sqrt{3}}{2}}\right)(0) + \left(\left(-\frac{1}{4x^2} - \frac{\frac{1}{2}+\frac{\sqrt{6+6i\sqrt{3}}}{12}}{\left(x+\frac{1}{2}-\frac{i\sqrt{3}}{2}\right)^2} - \frac{\frac{1}{2}+\frac{\sqrt{6-6i\sqrt{3}}}{12}}{\left(x+\frac{1}{2}+\frac{i\sqrt{3}}{2}\right)^2}\right) + \left(\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}z_1(x) &= p e^{\int \omega\,dx}\\ &= e^{\int\left(\frac{1}{4x} + \frac{\frac{1}{2}+\frac{\sqrt{6+6i\sqrt{3}}}{12}}{x+\frac{1}{2}-\frac{i\sqrt{3}}{2}} + \frac{\frac{1}{2}+\frac{\sqrt{6-6i\sqrt{3}}}{12}}{x+\frac{1}{2}+\frac{i\sqrt{3}}{2}}\right)dx}\\ &= 2\left(x^2+x+1\right)^{3/4}\sqrt{2}\,x^{1/4}\mathrm{e}^{-\frac{\sqrt{3}\,\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}{6}}\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}\\ &= z_1 e^{-\int \frac{1}{2}\frac{11x^3+11x^2+9x}{2x^4+2x^3+2x^2}\,dx}\\ &= z_1 e^{-\frac{\ln\left(x^2+x+1\right)}{4} - \frac{\sqrt{3}\,\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}{6} - \frac{9\ln(x)}{4}}\\ &= z_1\left(\frac{\mathrm{e}^{-\frac{\sqrt{3}\,\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}{6}}}{\left(x^2+x+1\right)^{1/4}x^{9/4}}\right)\end{aligned}$$

Which simplifies to

$$y_1 = \frac{2\sqrt{x^2+x+1}\,\mathrm{e}^{-\frac{\sqrt{3}\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}{3}}\sqrt{2}}{x^2}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{11x^3+11x^2+9x}{2x^4+2x^3+2x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{\mathrm{e}^{-\frac{\ln(x^2+x+1)}{2} - \frac{\sqrt{3}\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}{3} - \frac{9\ln(x)}{2}}}{(y_1)^2}\,dx \\
&= y_1 \left(\int \frac{\mathrm{e}^{-\frac{\ln(x^2+x+1)}{2} - \frac{\sqrt{3}\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}{3} - \frac{9\ln(x)}{2}}\,x^4\,\mathrm{e}^{\frac{2\sqrt{3}\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}{3}}}{8x^2+8x+8}\,dx\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{2\sqrt{x^2+x+1}\,\mathrm{e}^{-\frac{\sqrt{3}\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}{3}}\sqrt{2}}{x^2}\right) \\
&\quad + c_2 \left(\frac{2\sqrt{x^2+x+1}\,\mathrm{e}^{-\frac{\sqrt{3}\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}{3}}\sqrt{2}}{x^2}\left(\int \frac{\mathrm{e}^{-\frac{\ln(x^2+x+1)}{2} - \frac{\sqrt{3}\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}{3} - \frac{9\ln(x)}{2}}\,x^4\,\mathrm{e}^{\frac{2\sqrt{3}\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}{3}}}{8x^2+8x+8}\,dx\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve
$2x^2(x^2+x+1)\left(\frac{d^2}{dx^2}y(x)\right) + x(11x^2+11x+9)\left(\frac{d}{dx}y(x)\right) + (7x^2+10x+6)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2
  $\frac{d^2}{dx^2}y(x)$
- Isolate 2nd derivative
  $\frac{d^2}{dx^2}y(x) = -\frac{(7x^2+10x+6)y(x)}{2x^2(x^2+x+1)} - \frac{(11x^2+11x+9)\left(\frac{d}{dx}y(x)\right)}{2x(x^2+x+1)}$
- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea
  $\frac{d^2}{dx^2}y(x) + \frac{(11x^2+11x+9)\left(\frac{d}{dx}y(x)\right)}{2x(x^2+x+1)} + \frac{(7x^2+10x+6)y(x)}{2x^2(x^2+x+1)} = 0$
- ☐ Check to see if x_0 is a regular singular point
  - Define functions
    $\left[P_2(x) = \frac{11x^2+11x+9}{2x(x^2+x+1)}, P_3(x) = \frac{7x^2+10x+6}{2x^2(x^2+x+1)}\right]$
  - $x \cdot P_2(x)$ is analytic at $x = 0$

$\left(x \cdot P_2(x)\right)\Big|_{x=0} = \frac{9}{2}$

- ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $\left(x^2 \cdot P_3(x)\right)\Big|_{x=0} = 3$

- ◦ $x = 0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $2x^2(x^2+x+1)\left(\frac{d^2}{dx^2}y(x)\right) + x(11x^2+11x+9)\left(\frac{d}{dx}y(x)\right) + (7x^2+10x+6)\,y(x) = 0$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

- ◦ Convert $x^m \cdot y(x)$ to series expansion for $m = 0..2$

  $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- ◦ Shift index using $k->k-m$

  $x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- ◦ Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m = 1..3$

  $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$

- ◦ Shift index using $k->k+1-m$

  $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$

- ◦ Convert $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m = 2..4$

  $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r-2+m}$

- ◦ Shift index using $k->k+2-m$

  $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(2+r)\,(3+2r)\,x^r + \left(a_1(3+r)\,(5+2r) + a_0(5+2r)\,(2+r)\right)x^{1+r} + \left(\sum_{k=2}^{\infty} (a_k(k+r+2)\,(2k+\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(2+r)\,(3+2r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \left\{-2, -\frac{3}{2}\right\}$

- Each term must be 0

  $a_1(3+r)\,(5+2r) + a_0(5+2r)\,(2+r) = 0$

- Solve for the dependent coefficient(s)

  $a_1 = -\frac{(2+r)a_0}{3+r}$

- Each term in the series must be 0, giving the recursion relation

  $2((a_k + a_{k-2} + a_{k-1})\,k + (a_k + a_{k-2} + a_{k-1})\,r + 2a_k - a_{k-2} + a_{k-1})\left(k + r + \frac{3}{2}\right) = 0$

- Shift index using $k->k+2$

  $2((a_{k+2} + a_k + a_{k+1})\,(k+2) + (a_{k+2} + a_k + a_{k+1})\,r + 2a_{k+2} - a_k + a_{k+1})\left(k + \frac{7}{2} + r\right) = 0$

- Recursion relation that defines series solution to ODE

$$a_{k+2} = -\frac{ka_k + ka_{k+1} + ra_k + ra_{k+1} + a_k + 3a_{k+1}}{k+4+r}$$

- Recursion relation for $r = -2$

$$a_{k+2} = -\frac{ka_k + ka_{k+1} - a_k + a_{k+1}}{k+2}$$

- Solution for $r = -2$

$$\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k-2}, a_{k+2} = -\frac{ka_k + ka_{k+1} - a_k + a_{k+1}}{k+2}, a_1 = 0\right]$$

- Recursion relation for $r = -\frac{3}{2}$

$$a_{k+2} = -\frac{ka_k + ka_{k+1} - \frac{1}{2}a_k + \frac{3}{2}a_{k+1}}{k+\frac{5}{2}}$$

- Solution for $r = -\frac{3}{2}$

$$\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k-\frac{3}{2}}, a_{k+2} = -\frac{ka_k + ka_{k+1} - \frac{1}{2}a_k + \frac{3}{2}a_{k+1}}{k+\frac{5}{2}}, a_1 = -\frac{a_0}{3}\right]$$

- Combine solutions and rename parameters

$$\left[y(x) = \left(\sum_{k=0}^{\infty} a_k x^{k-2}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k-\frac{3}{2}}\right), a_{k+2} = -\frac{ka_k + ka_{k+1} - a_k + a_{k+1}}{k+2}, a_1 = 0, b_{k+2} = -\frac{kb_k + kb_{k+1} - \frac{1}{2}b_k +}{k+\frac{5}{2}}\right.$$

2.1.83 Problem 85

Internal problem ID [9255]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 85
Date solved : `Monday, January 27, 2025 at 06:00:36 PM`
CAS classification :
`[[_2nd_order, _with_linear_symmetries], [_2nd_order, _linear, '_with_symmetry_[0,F(x)]']`

Solve

$$3x^2y'' + 2x\left(-2x^2 + x + 1\right)y' + \left(-8x^2 + 2x\right)y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.359 (sec)

Writing the ode as

$$3x^2y'' + \left(-4x^3 + 2x^2 + 2x\right)y' + \left(-8x^2 + 2x\right)y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 3x^2 \\ B &= -4x^3 + 2x^2 + 2x \\ C &= -8x^2 + 2x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{4x^4 - 4x^3 + 15x^2 - 4x - 2}{9x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 4x^4 - 4x^3 + 15x^2 - 4x - 2 \\ t &= 9x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{4x^4 - 4x^3 + 15x^2 - 4x - 2}{9x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.150: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 4 \\ &= -2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 9x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{4x^2}{9} - \frac{4x}{9} + \frac{5}{3} - \frac{2}{9x^2} - \frac{4}{9x}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{2}{9}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{2}{3} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{3} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\
&= \sum_{i=0}^{1} a_i x^i \qquad (8)
\end{aligned}
$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$
\sqrt{r} \approx \frac{2x}{3} - \frac{1}{3} + \frac{7}{6x} + \frac{1}{4x^2} - \frac{17}{16x^3} - \frac{31}{32x^4} + \frac{85}{64x^5} + \frac{353}{128x^6} + \dots \qquad (9)
$$

Comparing Eq. (9) with Eq. (8) shows that

$$
a = \frac{2}{3}
$$

From Eq. (9) the sum up to $v = 1$ gives

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\
&= -\frac{1}{3} + \frac{2x}{3} \qquad (10)
\end{aligned}
$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$
\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{9} - \frac{4}{9}x + \frac{4}{9}x^2
$$

This shows that the coefficient of 1 in the above is $\frac{1}{9}$. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$
r = Q + \frac{R}{t}
$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{4x^4 - 4x^3 + 15x^2 - 4x - 2}{9x^2} \\
&= Q + \frac{R}{9x^2} \\
&= \left(\frac{4}{9}x^2 - \frac{4}{9}x + \frac{5}{3}\right) + \left(\frac{-4x - 2}{9x^2}\right) \\
&= \frac{4x^2}{9} - \frac{4x}{9} + \frac{5}{3} + \frac{-4x - 2}{9x^2}
\end{aligned}
$$

We see that the coefficient of the term x in the quotient is $\frac{5}{3}$. Now b can be found.

$$
\begin{aligned}
b &= \left(\frac{5}{3}\right) - \left(\frac{1}{9}\right) \\
&= \frac{14}{9}
\end{aligned}
$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= -\frac{1}{3} + \frac{2x}{3} \\
\alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{\frac{14}{9}}{\frac{2}{3}} - 1\right) &&= \frac{2}{3} \\
\alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{\frac{14}{9}}{\frac{2}{3}} - 1\right) &&= -\frac{5}{3}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{4x^4 - 4x^3 + 15x^2 - 4x - 2}{9x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{2}{3}$	$\frac{1}{3}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-2	$-\frac{1}{3} + \frac{2x}{3}$	$\frac{2}{3}$	$-\frac{5}{3}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{2}{3}$ then

$$\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^+\right) \\
&= \frac{2}{3} - \left(\frac{2}{3}\right) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x - c_1} \right) + (+)[\sqrt{r}]_\infty \\
&= \frac{2}{3x} + \left(-\frac{1}{3} + \frac{2x}{3} \right) \\
&= \frac{2}{3x} - \frac{1}{3} + \frac{2x}{3} \\
&= \frac{2}{3x} - \frac{1}{3} + \frac{2x}{3}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{2}{3x} - \frac{1}{3} + \frac{2x}{3}\right)(0) + \left(\left(-\frac{2}{3x^2} + \frac{2}{3}\right) + \left(\frac{2}{3x} - \frac{1}{3} + \frac{2x}{3}\right)^2 - \left(\frac{4x^4 - 4x^3 + 15x^2 - 4x - 2}{9x^2}\right)\right) = 0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx} \\
&= \mathrm{e}^{\int \left(\frac{2}{3x} - \frac{1}{3} + \frac{2x}{3}\right) dx} \\
&= x^{2/3} \mathrm{e}^{\frac{x(x-1)}{3}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{-4x^3 + 2x^2 + 2x}{3x^2}\, dx} \\
&= z_1 e^{\frac{x^2}{3} - \frac{x}{3} - \frac{\ln(x)}{3}} \\
&= z_1 \left(\frac{\mathrm{e}^{\frac{x(x-1)}{3}}}{x^{1/3}} \right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = x^{1/3} \mathrm{e}^{\frac{2x(x-1)}{3}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-4x^3 + 2x^2 + 2x}{3x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{\frac{2x^2}{3} - \frac{2x}{3} - \frac{2\ln(x)}{3}}}{(y_1)^2}\, dx \\
&= y_1 \left(\int \frac{\mathrm{e}^{\frac{2x^2}{3} - \frac{2x}{3} - \frac{2\ln(x)}{3}} \mathrm{e}^{-\frac{4x(x-1)}{3}}}{x^{2/3}}\, dx \right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(x^{1/3} \mathrm{e}^{\frac{2x(x-1)}{3}} \right) + c_2 \left(x^{1/3} \mathrm{e}^{\frac{2x(x-1)}{3}} \left(\int \frac{\mathrm{e}^{\frac{2x^2}{3} - \frac{2x}{3} - \frac{2\ln(x)}{3}} \mathrm{e}^{-\frac{4x(x-1)}{3}}}{x^{2/3}}\, dx \right) \right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$3x^2\left(\frac{d^2}{dx^2}y(x)\right)+2x(-2x^2+x+1)\left(\frac{d}{dx}y(x)\right)+(-8x^2+2x)\,y(x)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x)=\frac{2(4x-1)y(x)}{3x}+\frac{2(2x^2-x-1)\left(\frac{d}{dx}y(x)\right)}{3x}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x)-\frac{2(2x^2-x-1)\left(\frac{d}{dx}y(x)\right)}{3x}-\frac{2(4x-1)y(x)}{3x}=0$

□ Check to see if $x_0=0$ is a regular singular point

  ◦ Define functions

  $\left[P_2(x)=-\frac{2(2x^2-x-1)}{3x},P_3(x)=-\frac{2(4x-1)}{3x}\right]$

  ◦ $x\cdot P_2(x)$ is analytic at $x=0$

  $\left.(x\cdot P_2(x))\right|_{x=0}=\frac{2}{3}$

  ◦ $x^2\cdot P_3(x)$ is analytic at $x=0$

  $\left.(x^2\cdot P_3(x))\right|_{x=0}=0$

  ◦ $x=0$is a regular singular point

  Check to see if $x_0=0$ is a regular singular point

  $x_0=0$

- Multiply by denominators

  $3\left(\frac{d^2}{dx^2}y(x)\right)x+(-4x^2+2x+2)\left(\frac{d}{dx}y(x)\right)+(2-8x)\,y(x)=0$

- Assume series solution for $y(x)$

  $y(x)=\sum_{k=0}^{\infty}a_kx^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $x^m\cdot y(x)$ to series expansion for $m=0..1$

  $x^m\cdot y(x)=\sum_{k=0}^{\infty}a_kx^{k+r+m}$

  ◦ Shift index using $k->k-m$

  $x^m\cdot y(x)=\sum_{k=m}^{\infty}a_{k-m}x^{k+r}$

  ◦ Convert $x^m\cdot\left(\frac{d}{dx}y(x)\right)$ to series expansion for $m=0..2$

  $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,x^{k+r-1+m}$

  ◦ Shift index using $k->k+1-m$

  $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,x^{k+r}$

  ◦ Convert $x\cdot\left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

  $x\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,x^{k+r-1}$

  ◦ Shift index using $k->k+1$

  $x\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=-1}^{\infty}a_{k+1}(k+1+r)\,(k+r)\,x^{k+r}$

  Rewrite ODE with series expansions

$$a_0r(-1+3r)\,x^{-1+r}+(a_1(1+r)\,(2+3r)+2a_0(1+r))\,x^r+\left(\sum_{k=1}^{\infty}(a_{k+1}(k+1+r)\,(3k+2+3r)+\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $r(-1+3r)=0$
- Values of r that satisfy the indicial equation
  $r\in\left\{0,\frac{1}{3}\right\}$
- Each term must be 0
  $a_1(1+r)\,(2+3r)+2a_0(1+r)=0$
- Each term in the series must be 0, giving the recursion relation
  $(k+1+r)\,(3ka_{k+1}+3ra_{k+1}+2a_k-4a_{k-1}+2a_{k+1})=0$
- Shift index using $k->k+1$
  $(k+r+2)\,(3(k+1)\,a_{k+2}+3ra_{k+2}+2a_{k+1}-4a_k+2a_{k+2})=0$
- Recursion relation that defines series solution to ODE
  $a_{k+2}=\frac{2(-a_{k+1}+2a_k)}{3k+5+3r}$
- Recursion relation for $r=0$
  $a_{k+2}=\frac{2(-a_{k+1}+2a_k)}{3k+5}$
- Solution for $r=0$
  $\left[y(x)=\sum_{k=0}^{\infty}a_kx^k,a_{k+2}=\frac{2(-a_{k+1}+2a_k)}{3k+5},2a_1+2a_0=0\right]$
- Recursion relation for $r=\frac{1}{3}$
  $a_{k+2}=\frac{2(-a_{k+1}+2a_k)}{3k+6}$
- Solution for $r=\frac{1}{3}$
  $\left[y(x)=\sum_{k=0}^{\infty}a_kx^{k+\frac{1}{3}},a_{k+2}=\frac{2(-a_{k+1}+2a_k)}{3k+6},4a_1+\frac{8a_0}{3}=0\right]$
- Combine solutions and rename parameters
  $\left[y(x)=\left(\sum_{k=0}^{\infty}a_kx^k\right)+\left(\sum_{k=0}^{\infty}b_kx^{k+\frac{1}{3}}\right),a_{k+2}=\frac{2(-a_{k+1}+2a_k)}{3k+5},2a_1+2a_0=0,b_{k+2}=\frac{2(-b_{k+1}+2b_k)}{3k+6},4b_1+\right.$

Book : Collection of Kovacic problems
Section : section 1
Problem number : 86
Date solved : `Monday, January 27, 2025 at 06:00:37 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$12x^2(1+x)\,y'' + x\left(3x^2+35x+11\right)y' - \left(-5x^2-10x+1\right)y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.338 (sec)

Writing the ode as

$$\left(12x^3+12x^2\right)y'' + \left(3x^3+35x^2+11x\right)y' + \left(5x^2+10x-1\right)y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 12x^3+12x^2 \\ B &= 3x^3+35x^2+11x \\ C &= 5x^2+10x-1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{9x^4-30x^3-197x^2-190x-95}{576\left(x^2+x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 9x^4-30x^3-197x^2-190x-95 \\ t &= 576\left(x^2+x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{9x^4-30x^3-197x^2-190x-95}{576\left(x^2+x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.152: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 4 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 576(x^2 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{64} - \frac{7}{64\,(1+x)^2} - \frac{95}{576x^2} - \frac{1}{12\,(1+x)}$$

For the pole at $x = -1$ let b be the coefficient of $\frac{1}{(1+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{7}{64}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{8} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{8} \end{aligned}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{95}{576}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{19}{24} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{5}{24} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{8} - \frac{1}{3x} - \frac{29}{24x^2} - \frac{193}{72x^3} - \frac{3017}{216x^4} - \frac{40009}{648x^5} - \frac{642029}{1944x^6} - \frac{10350493}{5832x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{8}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{8} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{64}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{9x^4 - 30x^3 - 197x^2 - 190x - 95}{576x^4 + 1152x^3 + 576x^2} \\ &= Q + \frac{R}{576x^4 + 1152x^3 + 576x^2} \\ &= \left(\frac{1}{64}\right) + \left(\frac{-48x^3 - 206x^2 - 190x - 95}{576x^4 + 1152x^3 + 576x^2}\right) \\ &= \frac{1}{64} + \frac{-48x^3 - 206x^2 - 190x - 95}{576x^4 + 1152x^3 + 576x^2} \end{aligned}$$

Since the degree of t is 4, then we see that the coefficient of the term x^3 in the remainder R is -48. Dividing this by leading coefficient in t which is 576 gives $-\frac{1}{12}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{1}{12}\right) - (0) \\ &= -\frac{1}{12} \end{aligned}$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \frac{1}{8} \\
\alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{1}{12}}{\frac{1}{8}} - 0\right) &&= -\frac{1}{3} \\
\alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{1}{12}}{\frac{1}{8}} - 0\right) &&= \frac{1}{3}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{9x^4 - 30x^3 - 197x^2 - 190x - 95}{576\left(x^2+x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
-1	2	0	$\frac{7}{8}$	$\frac{1}{8}$
0	2	0	$\frac{19}{24}$	$\frac{5}{24}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
0	$\frac{1}{8}$	$-\frac{1}{3}$	$\frac{1}{3}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = \frac{1}{3}$ then

$$
\begin{aligned}
d &= \alpha_\infty^{-} - \left(\alpha_{c_1}^{-} + \alpha_{c_2}^{-}\right) \\
&= \frac{1}{3} - \left(\frac{1}{3}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{-}}{x-c_2}\right) + (-)[\sqrt{r}]_\infty \\
&= \frac{1}{8+8x} + \frac{5}{24x} + (-)\left(\frac{1}{8}\right) \\
&= \frac{1}{8+8x} + \frac{5}{24x} - \frac{1}{8} \\
&= \frac{1}{8+8x} + \frac{5}{24x} - \frac{1}{8}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(\frac{1}{8+8x}+\frac{5}{24x}-\frac{1}{8}\right)(0)+\left(\left(-\frac{1}{8\left(1+x\right)^{2}}-\frac{5}{24x^{2}}\right)+\left(\frac{1}{8+8x}+\frac{5}{24x}-\frac{1}{8}\right)^{2}-\left(\frac{9x^{4}-30x^{3}-19}{576\left(x\right.}\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z''=rz$ is

$$\begin{aligned}
z_1(x) &= pe^{\int \omega\,dx} \\
&= \mathrm{e}^{\int \left(\frac{1}{8+8x}+\frac{5}{24x}-\frac{1}{8}\right)dx} \\
&= x^{5/24}(1+x)^{1/8}\,\mathrm{e}^{-\frac{x}{8}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{3x^3+35x^2+11x}{12x^3+12x^2}\,dx} \\
&= z_1 e^{-\frac{x}{8}-\frac{11\ln(x)}{24}-\frac{7\ln(1+x)}{8}} \\
&= z_1\left(\frac{\mathrm{e}^{-\frac{x}{8}}}{x^{11/24}\left(1+x\right)^{7/8}}\right)
\end{aligned}$$

Which simplifies to

$$y_1=\frac{\mathrm{e}^{-\frac{x}{4}}}{x^{1/4}\left(1+x\right)^{3/4}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2=y_1\int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1\int \frac{e^{\int -\frac{3x^3+35x^2+11x}{12x^3+12x^2}\,dx}}{\left(y_1\right)^2}\,dx \\
&= y_1\int \frac{e^{-\frac{x}{4}-\frac{11\ln(x)}{12}-\frac{7\ln(1+x)}{4}}}{\left(y_1\right)^2}\,dx \\
&= y_1\left(\int \mathrm{e}^{-\frac{x}{4}-\frac{11\ln(x)}{12}-\frac{7\ln(1+x)}{4}}\sqrt{x}\left(1+x\right)^{3/2}\mathrm{e}^{\frac{x}{2}}\,dx\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{\mathrm{e}^{-\frac{x}{4}}}{x^{1/4}\left(1+x\right)^{3/4}}\right)+c_2\left(\frac{\mathrm{e}^{-\frac{x}{4}}}{x^{1/4}\left(1+x\right)^{3/4}}\left(\int \mathrm{e}^{-\frac{x}{4}-\frac{11\ln(x)}{12}-\frac{7\ln(1+x)}{4}}\sqrt{x}\left(1+x\right)^{3/2}\mathrm{e}^{\frac{x}{2}}\,dx\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$12x^2(x+1)\left(\frac{d^2}{dx^2}y(x)\right)+x(3x^2+35x+11)\left(\frac{d}{dx}y(x)\right)-(-5x^2-10x+1)\,y(x)=0$

- Highest derivative means the order of the ODE is 2

$\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

$\frac{d^2}{dx^2}y(x)=-\frac{(5x^2+10x-1)y(x)}{12(x+1)x^2}-\frac{(3x^2+35x+11)\left(\frac{d}{dx}y(x)\right)}{12x(x+1)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

$\frac{d^2}{dx^2}y(x)+\frac{(3x^2+35x+11)\left(\frac{d}{dx}y(x)\right)}{12x(x+1)}+\frac{(5x^2+10x-1)y(x)}{12(x+1)x^2}=0$

☐ Check to see if x_0 is a regular singular point

- ○ Define functions

$\left[P_2(x)=\frac{3x^2+35x+11}{12x(x+1)},P_3(x)=\frac{5x^2+10x-1}{12(x+1)x^2}\right]$

- ○ $(x+1)\cdot P_2(x)$ is analytic at $x=-1$

$\left.((x+1)\cdot P_2(x))\right|_{x=-1}=\frac{7}{4}$

- ○ $(x+1)^2\cdot P_3(x)$ is analytic at $x=-1$

$\left.((x+1)^2\cdot P_3(x))\right|_{x=-1}=0$

- ○ $x=-1$is a regular singular point

Check to see if x_0 is a regular singular point

$x_0=-1$

- Multiply by denominators

$12x^2(x+1)\left(\frac{d^2}{dx^2}y(x)\right)+x(3x^2+35x+11)\left(\frac{d}{dx}y(x)\right)+(5x^2+10x-1)\,y(x)=0$

- Change variables using $x=u-1$ so that the regular singular point is at $u=0$

$(12u^3-24u^2+12u)\left(\frac{d^2}{du^2}y(u)\right)+(3u^3+26u^2-50u+21)\left(\frac{d}{du}y(u)\right)+(5u^2-6)\,y(u)=0$

- Assume series solution for $y(u)$

$y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

☐ Rewrite ODE with series expansions

- ○ Convert $u^m\cdot y(u)$ to series expansion for $m=0..2$

$u^m\cdot y(u)=\sum_{k=0}^{\infty}a_k u^{k+r+m}$

- ○ Shift index using $k->k-m$

$u^m\cdot y(u)=\sum_{k=m}^{\infty}a_{k-m}u^{k+r}$

- ○ Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..3$

$u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,u^{k+r-1+m}$

- ○ Shift index using $k->k+1-m$

$u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,u^{k+r}$

- ○ Convert $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m=1..3$

$u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)(k+r-1)\,u^{k+r-2+m}$

- ○ Shift index using $k->k+2-m$

$$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\, u^{k+r}$$

Rewrite ODE with series expansions

$$3a_0r(3+4r)\, u^{-1+r} + (3a_1(1+r)(7+4r) - 2a_0(3+4r)(1+3r))\, u^r + (3a_2(2+r)(11+4r) - 2a_1($$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $3r(3+4r) = 0$
- Values of r that satisfy the indicial equation
  $r \in \left\{0, -\frac{3}{4}\right\}$
- The coefficients of each power of u must be 0
  $[3a_1(1+r)(7+4r) - 2a_0(3+4r)(1+3r) = 0, 3a_2(2+r)(11+4r) - 2a_1(7+4r)(4+3r) + 2a_0r($
- Solve for the dependent coefficient(s)
  $\left\{a_1 = \frac{2a_0(12r^2+13r+3)}{3(4r^2+11r+7)}, a_2 = \frac{2a_0(54r^3+135r^2+101r+24)}{9(4r^3+23r^2+41r+22)}\right\}$
- Each term in the series must be 0, giving the recursion relation
  $12(-2a_k + a_{k-1} + a_{k+1})\, k^2 + (24(-2a_k + a_{k-1} + a_{k+1})\, r - 26a_k + 3a_{k-2} - 10a_{k-1} + 33a_{k+1})\, k + 12$
- Shift index using $k- > k+2$
  $12(-2a_{k+2} + a_{k+1} + a_{k+3})\,(k+2)^2 + (24(-2a_{k+2} + a_{k+1} + a_{k+3})\, r - 26a_{k+2} + 3a_k - 10a_{k+1} + 33a_k$
- Recursion relation that defines series solution to ODE
  $a_{k+3} = -\frac{12k^2a_{k+1} - 24k^2a_{k+2} + 24kra_{k+1} - 48kra_{k+2} + 12r^2a_{k+1} - 24r^2a_{k+2} + 3ka_k + 38ka_{k+1} - 122ka_{k+2} + 3ra_k + 38ra_{k+1} - 122ra_{k+}}{3(4k^2+8kr+4r^2+27k+27r+45)}$
- Recursion relation for $r = 0$
  $a_{k+3} = -\frac{12k^2a_{k+1} - 24k^2a_{k+2} + 3ka_k + 38ka_{k+1} - 122ka_{k+2} + 5a_k + 26a_{k+1} - 154a_{k+2}}{3(4k^2+27k+45)}$
- Solution for $r = 0$
  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+3} = -\frac{12k^2a_{k+1} - 24k^2a_{k+2} + 3ka_k + 38ka_{k+1} - 122ka_{k+2} + 5a_k + 26a_{k+1} - 154a_{k+2}}{3(4k^2+27k+45)}, a_1 = \frac{2a_0}{7}, a_2 = \right.$
- Revert the change of variables $u = x+1$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k(x+1)^k, a_{k+3} = -\frac{12k^2a_{k+1} - 24k^2a_{k+2} + 3ka_k + 38ka_{k+1} - 122ka_{k+2} + 5a_k + 26a_{k+1} - 154a_{k+2}}{3(4k^2+27k+45)}, a_1 = \frac{2a_0}{7}, \right.$
- Recursion relation for $r = -\frac{3}{4}$
  $a_{k+3} = -\frac{12k^2a_{k+1} - 24k^2a_{k+2} + 3ka_k + 20ka_{k+1} - 86ka_{k+2} + \frac{11}{4}a_k + \frac{17}{4}a_{k+1} - 76a_{k+2}}{3(4k^2+21k+27)}$
- Solution for $r = -\frac{3}{4}$
  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k-\frac{3}{4}}, a_{k+3} = -\frac{12k^2a_{k+1} - 24k^2a_{k+2} + 3ka_k + 20ka_{k+1} - 86ka_{k+2} + \frac{11}{4}a_k + \frac{17}{4}a_{k+1} - 76a_{k+2}}{3(4k^2+21k+27)}, a_1 = 0, a_2 = \right.$
- Revert the change of variables $u = x+1$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k(x+1)^{k-\frac{3}{4}}, a_{k+3} = -\frac{12k^2a_{k+1} - 24k^2a_{k+2} + 3ka_k + 20ka_{k+1} - 86ka_{k+2} + \frac{11}{4}a_k + \frac{17}{4}a_{k+1} - 76a_{k+2}}{3(4k^2+21k+27)}, a_1 = 0, \right.$
- Combine solutions and rename parameters
  $\left[y(x) = \left(\sum_{k=0}^{\infty} a_k(x+1)^k\right) + \left(\sum_{k=0}^{\infty} b_k(x+1)^{k-\frac{3}{4}}\right), a_{k+3} = -\frac{12k^2a_{k+1} - 24k^2a_{k+2} + 3ka_k + 38ka_{k+1} - 122ka_{k+2} + 5}{3(4k^2+27k+45)}\right.$

2.1.85 Problem 87

Internal problem ID [9257]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 87
Date solved : `Monday, January 27, 2025 at 06:00:37 PM`
CAS classification :
`[[_2nd_order, _with_linear_symmetries], [_2nd_order, _linear, '_with_symmetry_[0,F(x)]']`

Solve

$$x^2\left(10x^2+x+5\right)y''+x\left(48x^2+3x+4\right)y'+\left(36x^2+x\right)y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 1.019 (sec)

Writing the ode as

$$\left(10x^4+x^3+5x^2\right)y''+\left(48x^3+3x^2+4x\right)y'+\left(36x^2+x\right)y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A&=10x^4+x^3+5x^2\\ B&=48x^3+3x^2+4x\\ C&=36x^2+x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r&=\frac{s}{t} \\ &=\frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{-96x^4-16x^3-97x^2-12x-24}{4\left(10x^3+x^2+5x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s&=-96x^4-16x^3-97x^2-12x-24\\ t&=4\left(10x^3+x^2+5x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{-96x^4 - 16x^3 - 97x^2 - 12x - 24}{4\left(10x^3 + x^2 + 5x\right)^2} \right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.154: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 4 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(10x^3 + x^2 + 5x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -\frac{1}{20} + \frac{i\sqrt{199}}{20}$ of order 2. There is a pole at $x = -\frac{1}{20} - \frac{i\sqrt{199}}{20}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$\begin{aligned} r = &-\frac{6}{25x^2} - \frac{3}{125x} + \frac{-\frac{1}{19900} - \frac{i\sqrt{199}}{1990}}{\left(x + \frac{1}{20} - \frac{i\sqrt{199}}{20}\right)^2} \\ &+ \frac{-\frac{1}{19900} + \frac{i\sqrt{199}}{1990}}{\left(x + \frac{1}{20} + \frac{i\sqrt{199}}{20}\right)^2} + \frac{\frac{3}{250} - \frac{647i\sqrt{199}}{9900250}}{x + \frac{1}{20} - \frac{i\sqrt{199}}{20}} + \frac{\frac{3}{250} + \frac{647i\sqrt{199}}{9900250}}{x + \frac{1}{20} + \frac{i\sqrt{199}}{20}} \end{aligned}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{6}{25}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{3}{5} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{2}{5} \end{aligned}$$

For the pole at $x = -\frac{1}{20} + \frac{i\sqrt{199}}{20}$ let b be the coefficient of $\frac{1}{\left(x+\frac{1}{20}-\frac{i\sqrt{199}}{20}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{19900} - \frac{i\sqrt{199}}{1990}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} + \frac{\sqrt{989826 - 1990i\sqrt{199}}}{1990} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} - \frac{\sqrt{989826 - 1990i\sqrt{199}}}{1990}
\end{aligned}
$$

For the pole at $x = -\frac{1}{20} - \frac{i\sqrt{199}}{20}$ let b be the coefficient of $\frac{1}{\left(x+\frac{1}{20}+\frac{i\sqrt{199}}{20}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{19900} + \frac{i\sqrt{199}}{1990}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} + \frac{\sqrt{989826 + 1990i\sqrt{199}}}{1990} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} - \frac{\sqrt{989826 + 1990i\sqrt{199}}}{1990}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = \frac{-96x^4 - 16x^3 - 97x^2 - 12x - 24}{4\left(10x^3 + x^2 + 5x\right)^2}
$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{6}{25}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{5} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{2}{5}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{-96x^4 - 16x^3 - 97x^2 - 12x - 24}{4\left(10x^3 + x^2 + 5x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{3}{5}$	$\frac{2}{5}$
$-\frac{1}{20} + \frac{i\sqrt{199}}{20}$	2	0	$\frac{1}{2} + \frac{\sqrt{989826-1990i\sqrt{199}}}{1990}$	$\frac{1}{2} - \frac{\sqrt{989826-1990i\sqrt{199}}}{1990}$
$-\frac{1}{20} - \frac{i\sqrt{199}}{20}$	2	0	$\frac{1}{2} + \frac{\sqrt{989826+1990i\sqrt{199}}}{1990}$	$\frac{1}{2} - \frac{\sqrt{989826+1990i\sqrt{199}}}{1990}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{3}{5}$	$\frac{2}{5}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying

$\alpha_\infty^+ = \frac{3}{5}$ then

$$\begin{aligned} d &= \alpha_\infty^+ - \left(\alpha_{c_1}^+ + \alpha_{c_2}^- + \alpha_{c_3}^-\right) \\ &= \frac{3}{5} - \left(\frac{3}{5}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2}\right) + \left((-)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^-}{x-c_3}\right) + (+)[\sqrt{r}]_\infty \\ &= \frac{3}{5x} + \frac{\frac{1}{2} - \frac{\sqrt{989826-1990i\sqrt{199}}}{1990}}{x + \frac{1}{20} - \frac{i\sqrt{199}}{20}} + \frac{\frac{1}{2} - \frac{\sqrt{989826+1990i\sqrt{199}}}{1990}}{x + \frac{1}{20} + \frac{i\sqrt{199}}{20}} + (0) \\ &= \frac{3}{5x} + \frac{\frac{1}{2} - \frac{\sqrt{989826-1990i\sqrt{199}}}{1990}}{x + \frac{1}{20} - \frac{i\sqrt{199}}{20}} + \frac{\frac{1}{2} - \frac{\sqrt{989826+1990i\sqrt{199}}}{1990}}{x + \frac{1}{20} + \frac{i\sqrt{199}}{20}} \\ &= \frac{12x^2 + x + 6}{20x^3 + 2x^2 + 10x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{3}{5x} + \frac{\frac{1}{2} - \frac{\sqrt{989826-1990i\sqrt{199}}}{1990}}{x + \frac{1}{20} - \frac{i\sqrt{199}}{20}} + \frac{\frac{1}{2} - \frac{\sqrt{989826+1990i\sqrt{199}}}{1990}}{x + \frac{1}{20} + \frac{i\sqrt{199}}{20}}\right)(0) + \left(\left(-\frac{3}{5x^2} - \frac{\frac{1}{2} - \frac{\sqrt{989826-1990i\sqrt{199}}}{1990}}{\left(x + \frac{1}{20} - \frac{i\sqrt{199}}{20}\right)^2} - \right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega\, dx} \\ &= e^{\int \left(\frac{3}{5x} + \frac{\frac{1}{2} - \frac{\sqrt{989826-1990i\sqrt{199}}}{1990}}{x + \frac{1}{20} - \frac{i\sqrt{199}}{20}} + \frac{\frac{1}{2} - \frac{\sqrt{989826+1990i\sqrt{199}}}{1990}}{x + \frac{1}{20} + \frac{i\sqrt{199}}{20}}\right) dx} \\ &= x^{3/5} e^{-\frac{\sqrt{199}\arctan\left(\frac{(20x+1)\sqrt{199}}{199}\right)}{995}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{48x^3+3x^2+4x}{10x^4+x^3+5x^2}\, dx} \\ &= z_1 e^{-\ln(10x^2+x+5) - \frac{\sqrt{199}\arctan\left(\frac{(20x+1)\sqrt{199}}{199}\right)}{995} - \frac{2\ln(x)}{5}} \\ &= z_1 \left(\frac{e^{-\frac{\sqrt{199}\arctan\left(\frac{(20x+1)\sqrt{199}}{199}\right)}{995}}}{(10x^2 + x + 5)\, x^{2/5}} \right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{x^{1/5} e^{-\frac{2\sqrt{199}\, \arctan\left(\frac{(20x+1)\sqrt{199}}{199}\right)}{995}}}{10x^2 + x + 5}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{48x^3+3x^2+4x}{10x^4+x^3+5x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-2\ln(10x^2+x+5) - \frac{2\sqrt{199}\, \arctan\left(\frac{(20x+1)\sqrt{199}}{199}\right)}{995} - \frac{4\ln(x)}{5}}}{(y_1)^2}\, dx \\
&= y_1 \left(\int \frac{e^{-2\ln(10x^2+x+5) - \frac{2\sqrt{199}\, \arctan\left(\frac{(20x+1)\sqrt{199}}{199}\right)}{995} - \frac{4\ln(x)}{5}} (10x^2+x+5)^2 e^{\frac{4\sqrt{199}\, \arctan\left(\frac{(20x+1)\sqrt{199}}{199}\right)}{995}}}{x^{2/5}} dx \right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{x^{1/5} e^{-\frac{2\sqrt{199}\, \arctan\left(\frac{(20x+1)\sqrt{199}}{199}\right)}{995}}}{10x^2+x+5} \right) \\
&\quad + c_2 \left(\frac{x^{1/5} e^{-\frac{2\sqrt{199}\, \arctan\left(\frac{(20x+1)\sqrt{199}}{199}\right)}{995}}}{10x^2+x+5} \right) \left(\int \frac{e^{-2\ln(10x^2+x+5) - \frac{2\sqrt{199}\, \arctan\left(\frac{(20x+1)\sqrt{199}}{199}\right)}{995} - \frac{4\ln(x)}{5}} (10x^2+x+5)^2 e^{\frac{4\sqrt{199}\, \mathrm{arc}}{}}}{x^{2/5}} \right.
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2(10x^2+x+5)\left(\frac{d^2}{dx^2}y(x)\right) + x(48x^2+3x+4)\left(\frac{d}{dx}y(x)\right) + (36x^2+x)\, y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{(36x+1)y(x)}{x(10x^2+x+5)} - \frac{(48x^2+3x+4)\left(\frac{d}{dx}y(x)\right)}{x(10x^2+x+5)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x) + \frac{(48x^2+3x+4)\left(\frac{d}{dx}y(x)\right)}{x(10x^2+x+5)} + \frac{(36x+1)y(x)}{x(10x^2+x+5)} = 0$

☐ Check to see if x_0 is a regular singular point

  ◦ Define functions

    $\left[P_2(x) = \frac{48x^2+3x+4}{x(10x^2+x+5)}, P_3(x) = \frac{36x+1}{x(10x^2+x+5)}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

$(x \cdot P_2(x))\bigg|_{x=0} = \frac{4}{5}$

- ∘ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $(x^2 \cdot P_3(x))\bigg|_{x=0} = 0$

- ∘ $x = 0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $x(10x^2 + x + 5)\left(\frac{d^2}{dx^2}y(x)\right) + (48x^2 + 3x + 4)\left(\frac{d}{dx}y(x)\right) + (36x + 1)\,y(x) = 0$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

- □ Rewrite ODE with series expansions
  - ∘ Convert $x^m \cdot y(x)$ to series expansion for $m = 0..1$

    $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

  - ∘ Shift index using $k- >k - m$

    $x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

  - ∘ Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m = 0..2$

    $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k (k + r)\, x^{k+r-1+m}$

  - ∘ Shift index using $k- >k + 1 - m$

    $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k + 1 - m + r)\, x^{k+r}$

  - ∘ Convert $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m = 1..3$

    $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k (k + r)(k + r - 1)\, x^{k+r-2+m}$

  - ∘ Shift index using $k- >k + 2 - m$

    $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k + 2 - m + r)(k + 1 - m + r)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0 r(-1 + 5r)\, x^{-1+r} + \left(a_1(1 + r)(4 + 5r) + a_0(1 + r)^2\right) x^r + \left(\sum_{k=1}^{\infty} (a_{k+1}(k + r + 1)(5k + 4 + 5r\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r(-1 + 5r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \left\{0, \frac{1}{5}\right\}$

- Each term must be 0

  $a_1(1 + r)(4 + 5r) + a_0(1 + r)^2 = 0$

- Each term in the series must be 0, giving the recursion relation

  $(k + r + 1)\left((a_k + 10a_{k-1} + 5a_{k+1})\, k + (a_k + 10a_{k-1} + 5a_{k+1})\, r + a_k + 8a_{k-1} + 4a_{k+1}\right) = 0$

- Shift index using $k- >k + 1$

  $(k + r + 2)\left((a_{k+1} + 10a_k + 5a_{k+2})(k + 1) + (a_{k+1} + 10a_k + 5a_{k+2})\, r + a_{k+1} + 8a_k + 4a_{k+2}\right) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{10ka_k + ka_{k+1} + 10ra_k + ra_{k+1} + 18a_k + 2a_{k+1}}{5k + 5r + 9}$

- Recursion relation for $r = 0$

$a_{k+2} = -\frac{10ka_k+ka_{k+1}+18a_k+2a_{k+1}}{5k+9}$

- Solution for $r = 0$

$$\left[y(x) = \sum_{k=0}^{\infty} a_k x^k, a_{k+2} = -\frac{10ka_k+ka_{k+1}+18a_k+2a_{k+1}}{5k+9}, 4a_1 + a_0 = 0\right]$$

- Recursion relation for $r = \frac{1}{5}$

$a_{k+2} = -\frac{10ka_k+ka_{k+1}+20a_k+\frac{11}{5}a_{k+1}}{5k+10}$

- Solution for $r = \frac{1}{5}$

$$\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{5}}, a_{k+2} = -\frac{10ka_k+ka_{k+1}+20a_k+\frac{11}{5}a_{k+1}}{5k+10}, 6a_1 + \frac{36a_0}{25} = 0\right]$$

- Combine solutions and rename parameters

$$\left[y(x) = \left(\sum_{k=0}^{\infty} a_k x^k\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{5}}\right), a_{k+2} = -\frac{10ka_k+ka_{k+1}+18a_k+2a_{k+1}}{5k+9}, 4a_1 + a_0 = 0, b_{k+2} = -\frac{10kb_k+\cdots}{}\right.$$

Maple trace

2.1.86 Problem 88

Internal problem ID [9258]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 88
Date solved : `Monday, January 27, 2025 at 06:00:39 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$18x^2(1+x)\,y''+3x\left(x^2+11x+5\right)y'-\left(-5x^2-2x+1\right)y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.417 (sec)

Writing the ode as

$$\left(18x^3+18x^2\right)y''+\left(3x^3+33x^2+15x\right)y'+\left(5x^2+2x-1\right)y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 18x^3+18x^2 \\ B &= 3x^3+33x^2+15x \\ C &= 5x^2+2x-1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r=\frac{x^4-18x^3-45x^2-18x-27}{144\left(x^2+x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^4-18x^3-45x^2-18x-27 \\ t &= 144\left(x^2+x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{x^4-18x^3-45x^2-18x-27}{144\left(x^2+x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.156: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 4 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 144(x^2 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{144} - \frac{35}{144\,(1+x)^2} - \frac{3}{16x^2} + \frac{1}{4x} - \frac{7}{18\,(1+x)}$$

For the pole at $x = -1$ let b be the coefficient of $\frac{1}{(1+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{35}{144}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{12} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{5}{12} \end{aligned}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{4} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{12} - \frac{5}{6x} - \frac{53}{12x^2} - \frac{523}{12x^3} - \frac{6659}{12x^4} - \frac{94267}{12x^5} - \frac{1432421}{12x^6} - \frac{22802941}{12x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{12}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{12} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{144}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^4 - 18x^3 - 45x^2 - 18x - 27}{144x^4 + 288x^3 + 144x^2} \\ &= Q + \frac{R}{144x^4 + 288x^3 + 144x^2} \\ &= \left(\frac{1}{144}\right) + \left(\frac{-20x^3 - 46x^2 - 18x - 27}{144x^4 + 288x^3 + 144x^2}\right) \\ &= \frac{1}{144} + \frac{-20x^3 - 46x^2 - 18x - 27}{144x^4 + 288x^3 + 144x^2} \end{aligned}$$

Since the degree of t is 4, then we see that the coefficient of the term x^3 in the remainder R is -20. Dividing this by leading coefficient in t which is 144 gives $-\frac{5}{36}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{5}{36}\right) - (0) \\ &= -\frac{5}{36} \end{aligned}$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \frac{1}{12} \\
\alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-\frac{5}{36}}{\frac{1}{12}} - 0\right) &= -\frac{5}{6} \\
\alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) = \frac{1}{2}\left(-\frac{-\frac{5}{36}}{\frac{1}{12}} - 0\right) = \frac{5}{6}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{x^4 - 18x^3 - 45x^2 - 18x - 27}{144\left(x^2 + x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
-1	2	0	$\frac{7}{12}$	$\frac{5}{12}$
0	2	0	$\frac{3}{4}$	$\frac{1}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{12}$	$-\frac{5}{6}$	$\frac{5}{6}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{5}{6}$ then

$$
\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^+ + \alpha_{c_2}^-\right) \\
&= \frac{5}{6} - \left(\frac{5}{6}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c}\right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x - c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x - c_2}\right) + (-)[\sqrt{r}]_\infty \\
&= \frac{7}{12\left(1 + x\right)} + \frac{1}{4x} + (-)\left(\frac{1}{12}\right) \\
&= \frac{7}{12\left(1 + x\right)} + \frac{1}{4x} - \frac{1}{12} \\
&= \frac{7}{12 + 12x} + \frac{1}{4x} - \frac{1}{12}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{7}{12\left(1+x\right)} + \frac{1}{4x} - \frac{1}{12}\right)(0) + \left(\left(-\frac{7}{12\left(1+x\right)^{2}} - \frac{1}{4x^{2}}\right) + \left(\frac{7}{12\left(1+x\right)} + \frac{1}{4x} - \frac{1}{12}\right)^{2} - \left(\frac{x^{4} - 18x^{3}}{1}\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx} \\
&= \mathrm{e}^{\int \left(\frac{7}{12(1+x)} + \frac{1}{4x} - \frac{1}{12}\right) dx} \\
&= x^{1/4} (1+x)^{7/12}\, \mathrm{e}^{-\frac{x}{12}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{3x^3+33x^2+15x}{18x^3+18x^2}\, dx} \\
&= z_1 e^{-\frac{x}{12} - \frac{5\ln(x)}{12} - \frac{5\ln(1+x)}{12}} \\
&= z_1 \left(\frac{\mathrm{e}^{-\frac{x}{12}}}{x^{5/12}\left(1+x\right)^{5/12}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{\left(1+x\right)^{1/6} \mathrm{e}^{-\frac{x}{6}}}{x^{1/6}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{3x^3+33x^2+15x}{18x^3+18x^2}\, dx}}{\left(y_1\right)^2}\, dx \\
&= y_1 \int \frac{e^{-\frac{x}{6} - \frac{5\ln(x)}{6} - \frac{5\ln(1+x)}{6}}}{\left(y_1\right)^2}\, dx \\
&= y_1 \left(\int \frac{\mathrm{e}^{-\frac{x}{6} - \frac{5\ln(x)}{6} - \frac{5\ln(1+x)}{6}} x^{1/3} \mathrm{e}^{\frac{x}{3}}}{\left(1+x\right)^{1/3}} dx\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{\left(1+x\right)^{1/6} \mathrm{e}^{-\frac{x}{6}}}{x^{1/6}}\right) + c_2 \left(\frac{\left(1+x\right)^{1/6} \mathrm{e}^{-\frac{x}{6}}}{x^{1/6}} \left(\int \frac{\mathrm{e}^{-\frac{x}{6} - \frac{5\ln(x)}{6} - \frac{5\ln(1+x)}{6}} x^{1/3} \mathrm{e}^{\frac{x}{3}}}{\left(1+x\right)^{1/3}} dx\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$18x^2(x+1)\left(\frac{d^2}{dx^2}y(x)\right)+3x(x^2+11x+5)\left(\frac{d}{dx}y(x)\right)-(-5x^2-2x+1)\,y(x)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x)=-\frac{(5x^2+2x-1)y(x)}{18(x+1)x^2}-\frac{(x^2+11x+5)\left(\frac{d}{dx}y(x)\right)}{6x(x+1)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x)+\frac{(x^2+11x+5)\left(\frac{d}{dx}y(x)\right)}{6x(x+1)}+\frac{(5x^2+2x-1)y(x)}{18(x+1)x^2}=0$

□ Check to see if x_0 is a regular singular point

  ○ Define functions

  $\left[P_2(x)=\frac{x^2+11x+5}{6x(x+1)},P_3(x)=\frac{5x^2+2x-1}{18(x+1)x^2}\right]$

  ○ $(x+1)\cdot P_2(x)$ is analytic at $x=-1$

  $\left.((x+1)\cdot P_2(x))\right|_{x=-1}=\frac{5}{6}$

  ○ $(x+1)^2\cdot P_3(x)$ is analytic at $x=-1$

  $\left.((x+1)^2\cdot P_3(x))\right|_{x=-1}=0$

  ○ $x=-1$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=-1$

- Multiply by denominators

  $18x^2(x+1)\left(\frac{d^2}{dx^2}y(x)\right)+3x(x^2+11x+5)\left(\frac{d}{dx}y(x)\right)+(5x^2+2x-1)\,y(x)=0$

- Change variables using $x=u-1$ so that the regular singular point is at $u=0$

  $(18u^3-36u^2+18u)\left(\frac{d^2}{du^2}y(u)\right)+(3u^3+24u^2-42u+15)\left(\frac{d}{du}y(u)\right)+(5u^2-8u+2)\,y(u)=0$

- Assume series solution for $y(u)$

  $y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

□ Rewrite ODE with series expansions

  ○ Convert $u^m\cdot y(u)$ to series expansion for $m=0..2$

  $u^m\cdot y(u)=\sum_{k=0}^{\infty}a_k u^{k+r+m}$

  ○ Shift index using $k->k-m$

  $u^m\cdot y(u)=\sum_{k=m}^{\infty}a_{k-m}u^{k+r}$

  ○ Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..3$

  $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,u^{k+r-1+m}$

  ○ Shift index using $k->k+1-m$

  $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,u^{k+r}$

  ○ Convert $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m=1..3$

  $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,u^{k+r-2+m}$

  ○ Shift index using $k->k+2-m$

$$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\,u^{k+r}$$

Rewrite ODE with series expansions

$$3a_0r(-1+6r)\,u^{-1+r} + (3a_1(1+r)(5+6r) - 2a_0(1+3r)(-1+6r))\,u^r + (3a_2(2+r)(11+6r) - 2$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $3r(-1+6r) = 0$
- Values of r that satisfy the indicial equation
  $r \in \left\{0, \frac{1}{6}\right\}$
- The coefficients of each power of u must be 0
  $[3a_1(1+r)(5+6r) - 2a_0(1+3r)(-1+6r) = 0, 3a_2(2+r)(11+6r) - 2a_1(4+3r)(5+6r) + 2a_0$
- Solve for the dependent coefficient(s)
  $\left\{a_1 = \frac{2a_0(18r^2+3r-1)}{3(6r^2+11r+5)}, a_2 = \frac{2a_0(81r^3+126r^2+21r+4)}{9(6r^3+29r^2+45r+22)}\right\}$
- Each term in the series must be 0, giving the recursion relation
  $18(-2a_k + a_{k-1} + a_{k+1})\,k^2 + 3(12(-2a_k + a_{k-1} + a_{k+1})\,r - 2a_k + a_{k-2} - 10a_{k-1} + 11a_{k+1})\,k + 18($
- Shift index using $k- >k+2$
  $18(-2a_{k+2} + a_{k+1} + a_{k+3})\,(k+2)^2 + 3(12(-2a_{k+2} + a_{k+1} + a_{k+3})\,r - 2a_{k+2} + a_k - 10a_{k+1} + 11a_{k+}$
- Recursion relation that defines series solution to ODE
  $a_{k+3} = -\frac{18k^2a_{k+1}-36k^2a_{k+2}+36kra_{k+1}-72kra_{k+2}+18r^2a_{k+1}-36r^2a_{k+2}+3ka_k+42ka_{k+1}-150ka_{k+2}+3ra_k+42ra_{k+1}-150ra_{k+}}{3(6k^2+12kr+6r^2+35k+35r+51)}$
- Recursion relation for $r = 0$
  $a_{k+3} = -\frac{18k^2a_{k+1}-36k^2a_{k+2}+3ka_k+42ka_{k+1}-150ka_{k+2}+5a_k+16a_{k+1}-154a_{k+2}}{3(6k^2+35k+51)}$
- Solution for $r = 0$
  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+3} = -\frac{18k^2a_{k+1}-36k^2a_{k+2}+3ka_k+42ka_{k+1}-150ka_{k+2}+5a_k+16a_{k+1}-154a_{k+2}}{3(6k^2+35k+51)}, a_1 = -\frac{2a_0}{15}, a_2 =\right.$
- Revert the change of variables $u = x+1$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k(x+1)^k, a_{k+3} = -\frac{18k^2a_{k+1}-36k^2a_{k+2}+3ka_k+42ka_{k+1}-150ka_{k+2}+5a_k+16a_{k+1}-154a_{k+2}}{3(6k^2+35k+51)}, a_1 = -\frac{2a}{15}\right.$
- Recursion relation for $r = \frac{1}{6}$
  $a_{k+3} = -\frac{18k^2a_{k+1}-36k^2a_{k+2}+3ka_k+48ka_{k+1}-162ka_{k+2}+\frac{11}{2}a_k+\frac{47}{2}a_{k+1}-180a_{k+2}}{3(6k^2+37k+57)}$
- Solution for $r = \frac{1}{6}$

2.1.87 Problem 89

Internal problem ID [9259]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 89
Date solved : `Monday, January 27, 2025 at 06:00:40 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$2x^2y'' + x(3+2x)\,y' - (1-x)\,y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.248 (sec)

Writing the ode as

$$2x^2y'' + \left(2x^2+3x\right)y' + (x-1)\,y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2x^2 \\ B &= 2x^2+3x \\ C &= x-1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{4x^2+4x+5}{16x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 4x^2+4x+5 \\ t &= 16x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{4x^2+4x+5}{16x^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.158: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} + \frac{5}{16x^2} + \frac{1}{4x}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{5}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{4} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} + \frac{1}{4x} + \frac{1}{4x^2} - \frac{1}{8x^3} + \frac{1}{16x^5} - \frac{3}{64x^6} - \frac{1}{128x^7} + \frac{11}{256x^8} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{4x^2 + 4x + 5}{16x^2} \\ &= Q + \frac{R}{16x^2} \\ &= \left(\frac{1}{4}\right) + \left(\frac{4x + 5}{16x^2}\right) \\ &= \frac{1}{4} + \frac{4x + 5}{16x^2} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is 4. Dividing this by leading coefficient in t which is 16 gives $\frac{1}{4}$. Now b can be found.

$$\begin{aligned} b &= \left(\frac{1}{4}\right) - (0) \\ &= \frac{1}{4} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{2} \\ \alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{\frac{1}{4}}{\frac{1}{2}} - 0\right) &&= \frac{1}{4} \\ \alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{\frac{1}{4}}{\frac{1}{2}} - 0\right) &&= -\frac{1}{4} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{4x^2 + 4x + 5}{16x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{5}{4}$	$-\frac{1}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	$\frac{1}{4}$	$-\frac{1}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -\frac{1}{4}$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\ &= -\frac{1}{4} - \left(-\frac{1}{4}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= -\frac{1}{4x} + (-)\left(\frac{1}{2}\right) \\ &= -\frac{1}{4x} - \frac{1}{2} \\ &= -\frac{1}{4x} - \frac{1}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(-\frac{1}{4x} - \frac{1}{2}\right)(0) + \left(\left(\frac{1}{4x^2}\right) + \left(-\frac{1}{4x} - \frac{1}{2}\right)^2 - \left(\frac{4x^2+4x+5}{16x^2}\right) \right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= e^{\int \left(-\frac{1}{4x} - \frac{1}{2}\right) dx} \\ &= \frac{e^{-\frac{x}{2}}}{x^{1/4}} \end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{2x^2+3x}{2x^2}\,dx} \\
&= z_1 e^{-\frac{x}{2}-\frac{3\ln(x)}{4}} \\
&= z_1 \left(\frac{e^{-\frac{x}{2}}}{x^{3/4}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{e^{-x}}{x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{2x^2+3x}{2x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-x-\frac{3\ln(x)}{2}}}{(y_1)^2}\,dx \\
&= y_1 \left(\sqrt{x}\,e^{x} - \frac{\sqrt{\pi}\,\operatorname{erfi}\left(\sqrt{x}\right)}{2}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{e^{-x}}{x}\right) + c_2 \left(\frac{e^{-x}}{x}\left(\sqrt{x}\,e^{x} - \frac{\sqrt{\pi}\,\operatorname{erfi}\left(\sqrt{x}\right)}{2}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$2x^2\left(\frac{d^2}{dx^2}y(x)\right) + x(2x+3)\left(\frac{d}{dx}y(x)\right) - (1-x)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{(x-1)y(x)}{2x^2} - \frac{(2x+3)\left(\frac{d}{dx}y(x)\right)}{2x}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x) + \frac{(2x+3)\left(\frac{d}{dx}y(x)\right)}{2x} + \frac{(x-1)y(x)}{2x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

    $\left[P_2(x) = \frac{2x+3}{2x}, P_3(x) = \frac{x-1}{2x^2}\right]$

- ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

  $\left(x \cdot P_2(x)\right)\bigg|_{x=0} = \frac{3}{2}$

- ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = -\frac{1}{2}$

- ◦ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- • Multiply by denominators

  $2x^2\left(\frac{d^2}{dx^2}y(x)\right) + x(2x+3)\left(\frac{d}{dx}y(x)\right) + (x-1)\,y(x) = 0$

- • Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

- □ Rewrite ODE with series expansions

  - ◦ Convert $x^m \cdot y(x)$ to series expansion for $m = 0..1$

    $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

  - ◦ Shift index using $k- >k - m$

    $x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

  - ◦ Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m = 1..2$

    $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$

  - ◦ Shift index using $k- >k + 1 - m$

    $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$

  - ◦ Convert $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

    $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(1+r)\,(-1+2r)\,x^r + \left(\sum_{k=1}^{\infty} \left(a_k(k+r+1)\,(2k+2r-1) + a_{k-1}(2k+2r-1)\right) x^{k+r}\right) = 0$

- • $a_0$cannot be 0 by assumption, giving the indicial equation

  $(1+r)\,(-1+2r) = 0$

- • Values of r that satisfy the indicial equation

  $r \in \left\{-1, \frac{1}{2}\right\}$

- • Each term in the series must be 0, giving the recursion relation

  $2\left(k+r-\frac{1}{2}\right)\left(a_k(k+r+1) + a_{k-1}\right) = 0$

- • Shift index using $k- >k + 1$

  $2\left(k+\frac{1}{2}+r\right)\left(a_{k+1}(k+2+r) + a_k\right) = 0$

- • Recursion relation that defines series solution to ODE

  $a_{k+1} = -\frac{a_k}{k+2+r}$

- • Recursion relation for $r = -1$

  $a_{k+1} = -\frac{a_k}{k+1}$

- • Solution for $r = -1$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k-1}, a_{k+1} = -\frac{a_k}{k+1}\right]$

- Recursion relation for $r = \frac{1}{2}$

  $a_{k+1} = -\frac{a_k}{k+\frac{5}{2}}$

- Solution for $r = \frac{1}{2}$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}, a_{k+1} = -\frac{a_k}{k+\frac{5}{2}}\right]$

- Combine solutions and rename parameters

  $\left[y(x) = \left(\sum_{k=0}^{\infty} a_k x^{k-1}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{2}}\right), a_{k+1} = -\frac{a_k}{k+1}, b_{k+1} = -\frac{b_k}{k+\frac{5}{2}}\right]$

2.1.88 Problem 90

Internal problem ID [9260]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 90
Date solved : `Monday, January 27, 2025 at 06:00:40 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$2x^2y'' + x(5+x)\,y' - (2-3x)\,y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.268 (sec)

Writing the ode as

$$2x^2y'' + \left(x^2+5x\right)y' + (3x-2)\,y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2x^2 \\ B &= x^2+5x \\ C &= 3x-2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2-14x+21}{16x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2-14x+21 \\ t &= 16x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2-14x+21}{16x^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.160: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{16} + \frac{21}{16x^2} - \frac{7}{8x}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{21}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{7}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{3}{4} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \qquad (8) \end{aligned}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{4} - \frac{7}{4x} - \frac{7}{2x^2} - \frac{49}{2x^3} - \frac{196}{x^4} - \frac{1715}{x^5} - \frac{31899}{2x^6} - \frac{309729}{2x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{4}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{4}\end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{16}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 - 14x + 21}{16x^2} \\ &= Q + \frac{R}{16x^2} \\ &= \left(\frac{1}{16}\right) + \left(\frac{-14x + 21}{16x^2}\right) \\ &= \frac{1}{16} + \frac{-14x + 21}{16x^2}\end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is -14. Dividing this by leading coefficient in t which is 16 gives $-\frac{7}{8}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{7}{8}\right) - (0) \\ &= -\frac{7}{8}\end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{4} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{7}{8}}{\frac{1}{4}} - 0\right) &&= -\frac{7}{4} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{7}{8}}{\frac{1}{4}} - 0\right) &&= \frac{7}{4}\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2 - 14x + 21}{16x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{7}{4}$	$-\frac{3}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{4}$	$-\frac{7}{4}$	$\frac{7}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{7}{4}$ then

$$\begin{aligned} d &= \alpha_\infty^- - (\alpha_{c_1}^+) \\ &= \frac{7}{4} - \left(\frac{7}{4}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{7}{4x} + (-)\left(\frac{1}{4}\right) \\ &= \frac{7}{4x} - \frac{1}{4} \\ &= -\frac{x-7}{4x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(\frac{7}{4x} - \frac{1}{4}\right)(0) + \left(\left(-\frac{7}{4x^2}\right) + \left(\frac{7}{4x} - \frac{1}{4}\right)^2 - \left(\frac{x^2 - 14x + 21}{16x^2}\right)\right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega\, dx} \\ &= e^{\int \left(\frac{7}{4x} - \frac{1}{4}\right) dx} \\ &= x^{7/4} e^{-\frac{x}{4}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{x^2+5x}{2x^2}\,dx} \\ &= z_1 e^{-\frac{x}{4}-\frac{5\ln(x)}{4}} \\ &= z_1\left(\frac{\mathrm{e}^{-\frac{x}{4}}}{x^{5/4}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \sqrt{x}\,\mathrm{e}^{-\frac{x}{2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{x^2+5x}{2x^2}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{-\frac{x}{2}-\frac{5\ln(x)}{2}}}{(y_1)^2}\,dx \\ &= y_1\left(-\frac{2\,\mathrm{e}^{\frac{x}{2}}}{5x^{5/2}} - \frac{2\,\mathrm{e}^{\frac{x}{2}}}{15x^{3/2}} - \frac{2\,\mathrm{e}^{\frac{x}{2}}}{15\sqrt{x}} - \frac{i\sqrt{\pi}\,\sqrt{2}\,\mathrm{erf}\left(\frac{i\sqrt{2}\,\sqrt{x}}{2}\right)}{15}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1y_1 + c_2y_2 \\ &= c_1\left(\sqrt{x}\,\mathrm{e}^{-\frac{x}{2}}\right) + c_2\left(\sqrt{x}\,\mathrm{e}^{-\frac{x}{2}}\left(-\frac{2\,\mathrm{e}^{\frac{x}{2}}}{5x^{5/2}} - \frac{2\,\mathrm{e}^{\frac{x}{2}}}{15x^{3/2}} - \frac{2\,\mathrm{e}^{\frac{x}{2}}}{15\sqrt{x}} - \frac{i\sqrt{\pi}\,\sqrt{2}\,\mathrm{erf}\left(\frac{i\sqrt{2}\,\sqrt{x}}{2}\right)}{15}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$2x^2\left(\frac{d^2}{dx^2}y(x)\right) + x(5+x)\left(\frac{d}{dx}y(x)\right) - (-3x+2)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{(3x-2)y(x)}{2x^2} - \frac{(5+x)\left(\frac{d}{dx}y(x)\right)}{2x}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x) + \frac{(5+x)\left(\frac{d}{dx}y(x)\right)}{2x} + \frac{(3x-2)y(x)}{2x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

$\left[P_2(x)=\frac{5+x}{2x}, P_3(x)=\frac{3x-2}{2x^2}\right]$

- $x\cdot P_2(x)$ is analytic at $x=0$

  $\left(x\cdot P_2(x)\right)\bigg|_{x=0}=\frac{5}{2}$

- $x^2\cdot P_3(x)$ is analytic at $x=0$

  $\left(x^2\cdot P_3(x)\right)\bigg|_{x=0}=-1$

- $x=0$is a regular singular point

  Check to see if $x_0=0$ is a regular singular point

  $x_0=0$

- Multiply by denominators

  $2x^2\left(\frac{d^2}{dx^2}y(x)\right)+x(5+x)\left(\frac{d}{dx}y(x)\right)+(3x-2)\,y(x)=0$

- Assume series solution for $y(x)$

  $y(x)=\sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $x^m\cdot y(x)$ to series expansion for $m=0..1$

  $x^m\cdot y(x)=\sum_{k=0}^{\infty} a_k x^{k+r+m}$

- Shift index using $k->k-m$

  $x^m\cdot y(x)=\sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- Convert $x^m\cdot\left(\frac{d}{dx}y(x)\right)$ to series expansion for $m=1..2$

  $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$

- Shift index using $k->k+1-m$

  $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$

- Convert $x^2\cdot\left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

  $x^2\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(2+r)\,(-1+2r)\,x^r+\left(\sum_{k=1}^{\infty}\left(a_k(k+r+2)\,(2k+2r-1)+a_{k-1}(k+r+2)\right)x^{k+r}\right)=0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(2+r)\,(-1+2r)=0$

- Values of r that satisfy the indicial equation

  $r\in\left\{-2,\frac{1}{2}\right\}$

- Each term in the series must be 0, giving the recursion relation

  $2\left(\left(k+r-\frac{1}{2}\right)a_k+\frac{a_{k-1}}{2}\right)(k+r+2)=0$

- Shift index using $k->k+1$

  $2\left(\left(k+\frac{1}{2}+r\right)a_{k+1}+\frac{a_k}{2}\right)(k+r+3)=0$

- Recursion relation that defines series solution to ODE

  $a_{k+1}=-\frac{a_k}{2k+1+2r}$

- Recursion relation for $r=-2$

  $a_{k+1}=-\frac{a_k}{2k-3}$

- Solution for $r=-2$

$$\left[y(x)=\sum_{k=0}^{\infty} a_k x^{k-2}, a_{k+1}=-\frac{a_k}{2k-3}\right]$$

- Recursion relation for $r=\frac{1}{2}$

  $a_{k+1}=-\frac{a_k}{2k+2}$

- Solution for $r=\frac{1}{2}$

$$\left[y(x)=\sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}, a_{k+1}=-\frac{a_k}{2k+2}\right]$$

- Combine solutions and rename parameters

$$\left[y(x)=\left(\sum_{k=0}^{\infty} a_k x^{k-2}\right)+\left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{2}}\right), a_{k+1}=-\frac{a_k}{2k-3}, b_{k+1}=-\frac{b_k}{2k+2}\right]$$

Solve

$$3x^2y'' + x(1+x)\,y' - y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.427 (sec)

Writing the ode as

$$3x^2y'' + \left(x^2+x\right)y' - y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 3x^2 \\ B &= x^2+x \\ C &= -1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2+2x+7}{36x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2+2x+7 \\ t &= 36x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2+2x+7}{36x^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.162: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 36x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{36} + \frac{7}{36x^2} + \frac{1}{18x}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{7}{36}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{6} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{6} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{6} + \frac{1}{6x} + \frac{1}{2x^2} - \frac{1}{2x^3} - \frac{1}{4x^4} + \frac{7}{4x^5} - \frac{7}{4x^6} - \frac{17}{4x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{6}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{6}\end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{36}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned}r &= \frac{s}{t} \\ &= \frac{x^2 + 2x + 7}{36x^2} \\ &= Q + \frac{R}{36x^2} \\ &= \left(\frac{1}{36}\right) + \left(\frac{2x + 7}{36x^2}\right) \\ &= \frac{1}{36} + \frac{2x + 7}{36x^2}\end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is 2. Dividing this by leading coefficient in t which is 36 gives $\frac{1}{18}$. Now b can be found.

$$\begin{aligned}b &= \left(\frac{1}{18}\right) - (0) \\ &= \frac{1}{18}\end{aligned}$$

Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= \frac{1}{6} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{\frac{1}{18}}{\frac{1}{6}} - 0\right) &= \frac{1}{6} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{\frac{1}{18}}{\frac{1}{6}} - 0\right) &= -\frac{1}{6}\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2 + 2x + 7}{36x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{7}{6}$	$-\frac{1}{6}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{6}$	$\frac{1}{6}$	$-\frac{1}{6}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -\frac{1}{6}$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\ &= -\frac{1}{6} - \left(-\frac{1}{6}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= -\frac{1}{6x} + (-)\left(\frac{1}{6}\right) \\ &= -\frac{1}{6x} - \frac{1}{6} \\ &= -\frac{1+x}{6x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{gathered} (0) + 2\left(-\frac{1}{6x} - \frac{1}{6}\right)(0) + \left(\left(\frac{1}{6x^2}\right) + \left(-\frac{1}{6x} - \frac{1}{6}\right)^2 - \left(\frac{x^2+2x+7}{36x^2}\right) \right) = 0 \\ 0 = 0 \end{gathered}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega\, dx} \\ &= e^{\int \left(-\frac{1}{6x} - \frac{1}{6}\right) dx} \\ &= \frac{e^{-\frac{x}{6}}}{x^{1/6}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{x^2+x}{3x^2}\,dx} \\
&= z_1 e^{-\frac{x}{6}-\frac{\ln(x)}{6}} \\
&= z_1 \left(\frac{\mathrm{e}^{-\frac{x}{6}}}{x^{1/6}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{\mathrm{e}^{-\frac{x}{3}}}{x^{1/3}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x^2+x}{3x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{x}{3}-\frac{\ln(x)}{3}}}{(y_1)^2}\,dx \\
&= y_1 \left(\int \mathrm{e}^{-\frac{x}{3}-\frac{\ln(x)}{3}} x^{2/3} \mathrm{e}^{\frac{2x}{3}}\,dx\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{\mathrm{e}^{-\frac{x}{3}}}{x^{1/3}}\right) + c_2 \left(\frac{\mathrm{e}^{-\frac{x}{3}}}{x^{1/3}} \left(\int \mathrm{e}^{-\frac{x}{3}-\frac{\ln(x)}{3}} x^{2/3} \mathrm{e}^{\frac{2x}{3}}\,dx\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$3x^2\left(\frac{d^2}{dx^2}y(x)\right) + x(x+1)\left(\frac{d}{dx}y(x)\right) - y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = \frac{y(x)}{3x^2} - \frac{(x+1)\left(\frac{d}{dx}y(x)\right)}{3x}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x) + \frac{(x+1)\left(\frac{d}{dx}y(x)\right)}{3x} - \frac{y(x)}{3x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

  $\left[P_2(x) = \frac{x+1}{3x}, P_3(x) = -\frac{1}{3x^2}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

$\left(x\cdot P_2(x)\right)\bigg|_{x=0} = \frac{1}{3}$

- ◦ $x^2\cdot P_3(x)$ is analytic at $x=0$

  $\left(x^2\cdot P_3(x)\right)\bigg|_{x=0} = -\frac{1}{3}$

- ◦ $x=0$is a regular singular point

  Check to see if $x_0=0$ is a regular singular point

  $x_0=0$

- Multiply by denominators

  $3x^2\left(\frac{d^2}{dx^2}y(x)\right)+x(x+1)\left(\frac{d}{dx}y(x)\right)-y(x)=0$

- Assume series solution for $y(x)$

  $y(x)=\sum_{k=0}^{\infty}a_k x^{k+r}$

□ Rewrite ODE with series expansions

- ◦ Convert $x^m\cdot\left(\frac{d}{dx}y(x)\right)$ to series expansion for $m=1..2$

  $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,x^{k+r-1+m}$

- ◦ Shift index using $k->k+1-m$

  $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,x^{k+r}$

- ◦ Convert $x^2\cdot\left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

  $x^2\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(1+3r)\,(-1+r)\,x^r+\left(\sum_{k=1}^{\infty}\left(a_k(3k+3r+1)\,(k+r-1)+a_{k-1}(k+r-1)\right)x^{k+r}\right)=0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(1+3r)\,(-1+r)=0$

- Values of r that satisfy the indicial equation

  $r\in\left\{1,-\frac{1}{3}\right\}$

- Each term in the series must be 0, giving the recursion relation

  $3\left(\left(k+r+\frac{1}{3}\right)a_k+\frac{a_{k-1}}{3}\right)(k+r-1)=0$

- Shift index using $k->k+1$

  $3\left(\left(k+\frac{4}{3}+r\right)a_{k+1}+\frac{a_k}{3}\right)(k+r)=0$

- Recursion relation that defines series solution to ODE

  $a_{k+1}=-\frac{a_k}{3k+4+3r}$

- Recursion relation for $r=1$

  $a_{k+1}=-\frac{a_k}{3k+7}$

- Solution for $r=1$

  $\left[y(x)=\sum_{k=0}^{\infty}a_k x^{k+1}, a_{k+1}=-\frac{a_k}{3k+7}\right]$

- Recursion relation for $r=-\frac{1}{3}$

  $a_{k+1}=-\frac{a_k}{3k+3}$

- Solution for $r=-\frac{1}{3}$

  $\left[y(x)=\sum_{k=0}^{\infty}a_k x^{k-\frac{1}{3}}, a_{k+1}=-\frac{a_k}{3k+3}\right]$

- Combine solutions and rename parameters

$$\left[y(x)=\left(\sum_{k=0}^{\infty}a_k x^{k+1}\right)+\left(\sum_{k=0}^{\infty}b_k x^{k-\frac{1}{3}}\right), a_{k+1}=-\frac{a_k}{3k+7}, b_{k+1}=-\frac{b_k}{3k+3}\right]$$

2.1.90 Problem 92

Internal problem ID [9262]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 92
Date solved : `Monday, January 27, 2025 at 06:00:42 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$2x^2y'' - xy' + (1-2x)\,y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.169 (sec)

Writing the ode as

$$2x^2y'' - xy' + (1-2x)\,y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2x^2 \\ B &= -x \\ C &= 1-2x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-3+16x}{16x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -3+16x \\ t &= 16x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{-3+16x}{16x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.164: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 1 \\ &= 1 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16x^2$. There is a pole at $x = 0$ of order 2. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [2]$$

Attempting to find a solution using case $n = 2$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{3}{16x^2} + \frac{1}{x}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} E_c &= \{2, 2 + 2\sqrt{1 + 4b}, 2 - 2\sqrt{1 + 4b}\} \\ &= \{1, 2, 3\} \end{aligned}$$

Since the order of r at ∞ is $1 < 2$ then

$$E_\infty = \{1\}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ for case 2 of Kovacic algorithm.

pole c location	pole order	E_c
0	2	$\{1, 2, 3\}$

Order of r at ∞	E_∞
1	$\{1\}$

Using the family $\{e_1, e_2, \dots, e_\infty\}$ given by

$$e_1 = 1, \; e_\infty = 1$$

Gives a non negative integer d (the degree of the polynomial $p(x)$), which is generated using

$$\begin{aligned} d &= \frac{1}{2}\left(e_\infty - \sum_{c\in\Gamma} e_c\right) \\ &= \frac{1}{2}(1 - (1)) \\ &= 0 \end{aligned}$$

We now form the following rational function

$$\begin{aligned} \theta &= \frac{1}{2}\sum_{c\in\Gamma} \frac{e_c}{x-c} \\ &= \frac{1}{2}\left(\frac{1}{(x-(0))}\right) \\ &= \frac{1}{2x} \end{aligned}$$

Now we search for a monic polynomial $p(x)$ of degree $d = 0$ such that

$$p''' + 3\theta p'' + \left(3\theta^2 + 3\theta' - 4r\right)p' + \left(\theta'' + 3\theta\theta' + \theta^3 - 4r\theta - 2r'\right)p = 0 \tag{1A}$$

Since $d = 0$, then letting

$$p = 1 \tag{2A}$$

Substituting p and θ into Eq. (1A) gives

$$0 = 0$$

And solving for p gives

$$p = 1$$

Now that $p(x)$ is found let

$$\begin{aligned} \phi &= \theta + \frac{p'}{p} \\ &= \frac{1}{2x} \end{aligned}$$

Let ω be the solution of

$$\omega^2 - \phi\omega + \left(\frac{1}{2}\phi' + \frac{1}{2}\phi^2 - r\right) = 0$$

Substituting the values for ϕ and r into the above equation gives

$$w^2 - \frac{w}{2x} + \frac{1-16x}{16x^2} = 0$$

Solving for ω gives

$$\omega = \frac{1+4\sqrt{x}}{4x}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= e^{\int \omega \, dx} \\ &= e^{\int \frac{1+4\sqrt{x}}{4x} dx} \\ &= x^{1/4} e^{2\sqrt{x}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-x}{2x^2}\,dx} \\
&= z_1 e^{\frac{\ln(x)}{4}} \\
&= z_1\left(x^{1/4}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \sqrt{x}\,\mathrm{e}^{2\sqrt{x}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-x}{2x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{\frac{\ln(x)}{2}}}{(y_1)^2}\,dx \\
&= y_1\left(-\frac{\mathrm{e}^{-4\sqrt{x}}}{2}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\sqrt{x}\,\mathrm{e}^{2\sqrt{x}}\right) + c_2\left(\sqrt{x}\,\mathrm{e}^{2\sqrt{x}}\left(-\frac{\mathrm{e}^{-4\sqrt{x}}}{2}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

2.1.91 Problem 93

Internal problem ID [9263]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 93
Date solved : `Monday, January 27, 2025 at 06:00:42 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$3x^2y'' + x(1+x)\,y' - (1+3x)\,y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.584 (sec)

Writing the ode as

$$3x^2y'' + \left(x^2+x\right)y' + (-3x-1)\,y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 3x^2 \\ B &= x^2+x \\ C &= -3x-1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2+38x+7}{36x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2+38x+7 \\ t &= 36x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2+38x+7}{36x^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.166: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 36x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{36} + \frac{7}{36x^2} + \frac{19}{18x}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{7}{36}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{6} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{6} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{6} + \frac{19}{6x} - \frac{59}{2x^2} + \frac{1121}{2x^3} - \frac{53041}{4x^4} + \frac{1404613}{4x^5} - \frac{39845827}{4x^6} + \frac{1184064097}{4x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{6}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{6} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{36}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 + 38x + 7}{36x^2} \\ &= Q + \frac{R}{36x^2} \\ &= \left(\frac{1}{36}\right) + \left(\frac{38x + 7}{36x^2}\right) \\ &= \frac{1}{36} + \frac{38x + 7}{36x^2} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is 38. Dividing this by leading coefficient in t which is 36 gives $\frac{19}{18}$. Now b can be found.

$$\begin{aligned} b &= \left(\frac{19}{18}\right) - (0) \\ &= \frac{19}{18} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{6} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{\frac{19}{18}}{\frac{1}{6}} - 0\right) &&= \frac{19}{6} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{\frac{19}{18}}{\frac{1}{6}} - 0\right) &&= -\frac{19}{6} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2 + 38x + 7}{36x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{7}{6}$	$-\frac{1}{6}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{6}$	$\frac{19}{6}$	$-\frac{19}{6}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{19}{6}$ then

$$\begin{aligned} d &= \alpha_\infty^+ - (\alpha_{c_1}^+) \\ &= \frac{19}{6} - \left(\frac{7}{6}\right) \\ &= 2 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1} \right) + (+)[\sqrt{r}]_\infty \\ &= \frac{7}{6x} + \left(\frac{1}{6}\right) \\ &= \frac{7}{6x} + \frac{1}{6} \\ &= \frac{7+x}{6x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 2$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x^2 + a_1 x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{gathered} (2) + 2\left(\frac{7}{6x} + \frac{1}{6}\right)(2x + a_1) + \left(\left(-\frac{7}{6x^2}\right) + \left(\frac{7}{6x} + \frac{1}{6}\right)^2 - \left(\frac{x^2 + 38x + 7}{36x^2}\right)\right) = 0 \\ \frac{(-a_1 + 20)\, x - 2a_0 + 7a_1}{3x} = 0 \end{gathered}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 70, a_1 = 20\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^2 + 20x + 70$$

Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \left(x^2+20x+70\right) \mathrm{e}^{\int \left(\frac{7}{6x}+\frac{1}{6}\right)dx} \\
&= \left(x^2+20x+70\right) \mathrm{e}^{\frac{x}{6}+\frac{7\ln(x)}{6}} \\
&= \left(x^2+20x+70\right) x^{7/6} \mathrm{e}^{\frac{x}{6}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{x^2+x}{3x^2}\, dx} \\
&= z_1 e^{-\frac{x}{6}-\frac{\ln(x)}{6}} \\
&= z_1 \left(\frac{\mathrm{e}^{-\frac{x}{6}}}{x^{1/6}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \left(x^2+20x+70\right) x
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x^2+x}{3x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-\frac{x}{3}-\frac{\ln(x)}{3}}}{(y_1)^2}\, dx \\
&= y_1 \left(\int \frac{\mathrm{e}^{-\frac{x}{3}-\frac{\ln(x)}{3}}}{\left(x^2+20x+70\right)^2 x^2} dx\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\left(x^2+20x+70\right) x\right) + c_2\left(\left(x^2+20x+70\right) x \left(\int \frac{\mathrm{e}^{-\frac{x}{3}-\frac{\ln(x)}{3}}}{\left(x^2+20x+70\right)^2 x^2} dx\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$3x^2\left(\frac{d^2}{dx^2}y(x)\right)+x(x+1)\left(\frac{d}{dx}y(x)\right)-(3x+1)\,y(x)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x)=\frac{(3x+1)y(x)}{3x^2}-\frac{(x+1)\left(\frac{d}{dx}y(x)\right)}{3x}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x)+\frac{(x+1)\left(\frac{d}{dx}y(x)\right)}{3x}-\frac{(3x+1)y(x)}{3x^2}=0$

☐ Check to see if $x_0=0$ is a regular singular point

  - Define functions

    $\left[P_2(x)=\frac{x+1}{3x}, P_3(x)=-\frac{3x+1}{3x^2}\right]$

  - $x\cdot P_2(x)$ is analytic at $x=0$

    $\left.(x\cdot P_2(x))\right|_{x=0}=\frac{1}{3}$

  - $x^2\cdot P_3(x)$ is analytic at $x=0$

    $\left.(x^2\cdot P_3(x))\right|_{x=0}=-\frac{1}{3}$

  - $x=0$is a regular singular point

  Check to see if $x_0=0$ is a regular singular point

  $x_0=0$

- Multiply by denominators

  $3x^2\left(\frac{d^2}{dx^2}y(x)\right)+x(x+1)\left(\frac{d}{dx}y(x)\right)+(-3x-1)\,y(x)=0$

- Assume series solution for $y(x)$

  $y(x)=\sum_{k=0}^{\infty}a_k x^{k+r}$

☐ Rewrite ODE with series expansions

  - Convert $x^m\cdot y(x)$ to series expansion for $m=0..1$

    $x^m\cdot y(x)=\sum_{k=0}^{\infty}a_k x^{k+r+m}$

  - Shift index using $k->k-m$

    $x^m\cdot y(x)=\sum_{k=m}^{\infty}a_{k-m}x^{k+r}$

  - Convert $x^m\cdot\left(\frac{d}{dx}y(x)\right)$ to series expansion for $m=1..2$

    $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,x^{k+r-1+m}$

  - Shift index using $k->k+1-m$

    $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,x^{k+r}$

  - Convert $x^2\cdot\left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

    $x^2\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(1+3r)\,(-1+r)\,x^r+\left(\sum_{k=1}^{\infty}\left(a_k(3k+3r+1)\,(k+r-1)+a_{k-1}(k-4+r)\right)x^{k+r}\right)=0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$(1+3r)(-1+r) = 0$

- Values of r that satisfy the indicial equation
  $r \in \left\{1, -\frac{1}{3}\right\}$
- Each term in the series must be 0, giving the recursion relation
  $3\left(k+r+\frac{1}{3}\right)(k+r-1)\, a_k + a_{k-1}(k-4+r) = 0$
- Shift index using $k->k+1$
  $3\left(k+\frac{4}{3}+r\right)(k+r)\, a_{k+1} + a_k(k+r-3) = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+1} = -\frac{a_k(k+r-3)}{(3k+4+3r)(k+r)}$
- Recursion relation for $r=1$; series terminates at $k=2$
  $a_{k+1} = -\frac{a_k(k-2)}{(3k+7)(k+1)}$
- Apply recursion relation for $k=0$
  $a_1 = \frac{2a_0}{7}$
- Apply recursion relation for $k=1$
  $a_2 = \frac{a_1}{20}$
- Express in terms of a_0
  $a_2 = \frac{a_0}{70}$
- Terminating series solution of the ODE for $r=1$. Use reduction of order to find the second li
  $y(x) = a_0 \cdot \left(1+\frac{2}{7}x+\frac{1}{70}x^2\right)$
- Recursion relation for $r=-\frac{1}{3}$
  $a_{k+1} = -\frac{a_k\left(k-\frac{10}{3}\right)}{(3k+3)\left(k-\frac{1}{3}\right)}$
- Solution for $r=-\frac{1}{3}$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k-\frac{1}{3}}, a_{k+1} = -\frac{a_k\left(k-\frac{10}{3}\right)}{(3k+3)\left(k-\frac{1}{3}\right)}\right]$
- Combine solutions and rename parameters
  $\left[y(x) = a_0 \cdot \left(1+\frac{2}{7}x+\frac{1}{70}x^2\right) + \left(\sum_{k=0}^{\infty} b_k x^{k-\frac{1}{3}}\right), b_{k+1} = -\frac{b_k\left(k-\frac{10}{3}\right)}{(3k+3)\left(k-\frac{1}{3}\right)}\right]$

2.1.92 Problem 94

Internal problem ID [9264]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 94
Date solved : `Monday, January 27, 2025 at 06:00:44 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$2x^2(3+x)\,y''+x(1+5x)\,y'+(1+x)\,y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.289 (sec)

Writing the ode as

$$\left(2x^3+6x^2\right)y''+\left(5x^2+x\right)y'+(1+x)\,y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A&=2x^3+6x^2\\ B&=5x^2+x \\ C&=1+x \end{aligned}\tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r&=\frac{s}{t} \\ &=\frac{2AB'-2BA'+B^2-4AC}{4A^2}\end{aligned}\tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{-3x^2-30x-35}{16\left(x^2+3x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s&=-3x^2-30x-35\\ t&=16\left(x^2+3x\right)^2\end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{-3x^2-30x-35}{16\left(x^2+3x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.168: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16(x^2 + 3x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -3$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{5}{108x} + \frac{5}{108\,(3 + x)} - \frac{35}{144x^2} + \frac{7}{36\,(3 + x)^2}$$

For the pole at $x = -3$ let b be the coefficient of $\frac{1}{(3+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{7}{36}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{7}{6} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{1}{6} \end{aligned}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{35}{144}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{7}{12} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{5}{12} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{-3x^2 - 30x - 35}{16\left(x^2 + 3x\right)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{3}{16}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{4} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{4}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{-3x^2 - 30x - 35}{16\left(x^2 + 3x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
-3	2	0	$\frac{7}{6}$	$-\frac{1}{6}$
0	2	0	$\frac{7}{12}$	$\frac{5}{12}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{3}{4}$	$\frac{1}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{4}$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^-\right) \\
&= \frac{1}{4} - \left(\frac{1}{4}\right) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2} \right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{1}{6\,(3+x)} + \frac{5}{12x} + (-)\,(0) \\
&= -\frac{1}{6\,(3+x)} + \frac{5}{12x} \\
&= \frac{x+5}{4x\,(3+x)}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\,p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{6(3+x)} + \frac{5}{12x}\right)(0) + \left(\left(\frac{1}{6(3+x)^2} - \frac{5}{12x^2}\right) + \left(-\frac{1}{6(3+x)} + \frac{5}{12x}\right)^2 - \left(\frac{-3x^2 - 30x - 35}{16(x^2+3x)^2}\right)\right)$$

$$0 =$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx} \\
&= e^{\int \left(-\frac{1}{6(3+x)} + \frac{5}{12x}\right) dx} \\
&= \frac{x^{5/12}}{(3+x)^{1/6}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{5x^2+x}{2x^3+6x^2}\, dx} \\
&= z_1 e^{-\frac{7\ln(3+x)}{6} - \frac{\ln(x)}{12}} \\
&= z_1 \left(\frac{1}{(3+x)^{7/6} x^{1/12}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{x^{1/3}}{(3+x)^{4/3}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{5x^2+x}{2x^3+6x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-\frac{7\ln(3+x)}{3} - \frac{\ln(x)}{6}}}{(y_1)^2}\, dx \\
&= y_1 \left(\int \frac{e^{-\frac{7\ln(3+x)}{3} - \frac{\ln(x)}{6}} (3+x)^{8/3}}{x^{2/3}} dx\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{x^{1/3}}{(3+x)^{4/3}}\right) + c_2 \left(\frac{x^{1/3}}{(3+x)^{4/3}} \left(\int \frac{e^{-\frac{7\ln(3+x)}{3} - \frac{\ln(x)}{6}} (3+x)^{8/3}}{x^{2/3}} dx\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$2x^2(x+3)\left(\frac{d^2}{dx^2}y(x)\right)+x(5x+1)\left(\frac{d}{dx}y(x)\right)+(x+1)\,y(x)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x)=-\frac{(x+1)y(x)}{2x^2(x+3)}-\frac{(5x+1)\left(\frac{d}{dx}y(x)\right)}{2x(x+3)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x)+\frac{(5x+1)\left(\frac{d}{dx}y(x)\right)}{2x(x+3)}+\frac{(x+1)y(x)}{2x^2(x+3)}=0$

- □ Check to see if x_0 is a regular singular point

Solve

$$x^2(4+x)\,y''-x(1-3x)\,y'+y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.520 (sec)

Writing the ode as

$$x^2(4+x)\,y''+\left(3x^2-x\right)y'+y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2(4+x) \\ B &= 3x^2-x \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{3x^2-6x-7}{4\left(x^2+4x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 3x^2-6x-7 \\ t &= 4\left(x^2+4x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{3x^2-6x-7}{4\left(x^2+4x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.170: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^2 + 4x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -4$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{5}{128\,(4 + x)} - \frac{5}{128x} - \frac{7}{64x^2} + \frac{65}{64\,(4 + x)^2}$$

For the pole at $x = -4$ let b be the coefficient of $\frac{1}{(4+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{65}{64}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{13}{8} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{5}{8} \end{aligned}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{7}{64}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{7}{8} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{8} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{3x^2 - 6x - 7}{4\left(x^2 + 4x\right)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{3}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{3x^2 - 6x - 7}{4\left(x^2 + 4x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
-4	2	0	$\frac{13}{8}$	$-\frac{5}{8}$
0	2	0	$\frac{7}{8}$	$\frac{1}{8}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -\frac{1}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^-\right) \\
&= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2} \right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{5}{8\,(4+x)} + \frac{1}{8x} + (-)\,(0) \\
&= -\frac{5}{8\,(4+x)} + \frac{1}{8x} \\
&= -\frac{x-1}{2x\,(4+x)}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{5}{8\,(4+x)} + \frac{1}{8x}\right)(0) + \left(\left(\frac{5}{8\,(4+x)^2} - \frac{1}{8x^2}\right) + \left(-\frac{5}{8\,(4+x)} + \frac{1}{8x}\right)^2 - \left(\frac{3x^2 - 6x - 7}{4\,(x^2+4x)^2}\right)\right) =$$

$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega\, dx} \\ &= \mathrm{e}^{\int \left(-\frac{5}{8(4+x)} + \frac{1}{8x}\right) dx} \\ &= \frac{x^{1/8}}{(4+x)^{5/8}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{3x^2 - x}{x^2(4+x)}\, dx} \\ &= z_1 e^{\frac{\ln(x)}{8} - \frac{13\ln(4+x)}{8}} \\ &= z_1 \left(\frac{x^{1/8}}{(4+x)^{13/8}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{x^{1/4}}{(4+x)^{9/4}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{3x^2 - x}{x^2(4+x)}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{\frac{\ln(x)}{4} - \frac{13\ln(4+x)}{4}}}{(y_1)^2}\, dx \\ &= y_1 \left(\int \frac{\mathrm{e}^{\frac{\ln(x)}{4} - \frac{13\ln(4+x)}{4}}(4+x)^{9/2}}{\sqrt{x}}\, dx\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\frac{x^{1/4}}{(4+x)^{9/4}}\right) + c_2 \left(\frac{x^{1/4}}{(4+x)^{9/4}}\left(\int \frac{\mathrm{e}^{\frac{\ln(x)}{4} - \frac{13\ln(4+x)}{4}}(4+x)^{9/2}}{\sqrt{x}}\, dx\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

□ Check to see if x_0 is a regular singular point

- Define functions

$\left[P_2(x) = \frac{3x-1}{x(x+4)}, P_3(x) = \frac{1}{x^2(x+4)}\right]$

- $(x+4)\cdot P_2(x)$ is analytic at $x=-4$

$\left((x+4)\cdot P_2(x)\right)\bigg|_{x=-4} = \frac{13}{4}$

- $(x+4)^2\cdot P_3(x)$ is analytic at $x=-4$

$\left((x+4)^2\cdot P_3(x)\right)\bigg|_{x=-4} = 0$

- $x=-4$is a regular singular point

Check to see if x_0 is a regular singular point

$x_0 = -4$

- Multiply by denominators

$x^2(x+4)\left(\frac{d^2}{dx^2}y(x)\right) + x(3x-1)\left(\frac{d}{dx}y(x)\right) + y(x) = 0$

- Change variables using $x = u-4$ so that the regular singular point is at $u=0$

$(u^3-8u^2+16u)\left(\frac{d^2}{du^2}y(u)\right) + (3u^2-25u+52)\left(\frac{d}{du}y(u)\right) + y(u) = 0$

- Assume series solution for $y(u)$

$y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

□ Rewrite ODE with series expansions

- Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..2$

$u^m\cdot\left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, u^{k+r-1+m}$

- Shift index using $k->k+1-m$

$u^m\cdot\left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$

- Convert $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m=1..3$

$u^m\cdot\left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, u^{k+r-2+m}$

- Shift index using $k->k+2-m$

$u^m\cdot\left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\, u^{k+r}$

Rewrite ODE with series expansions

$4a_0r(9+4r)\,u^{-1+r} + (4a_1(1+r)(13+4r) - a_0(8r^2+17r-1))\,u^r + \left(\sum_{k=1}^{\infty} (4a_{k+1}(k+1+r)(4k+\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$4r(9+4r)=0$$

- Values of r that satisfy the indicial equation

$$r \in \left\{0, -\frac{9}{4}\right\}$$

- Each term must be 0

$$4a_1(1+r)(13+4r) - a_0(8r^2+17r-1) = 0$$

- Each term in the series must be 0, giving the recursion relation

$$(-8a_k + a_{k-1} + 16a_{k+1})k^2 + (2(-8a_k + a_{k-1} + 16a_{k+1})r - 17a_k + 68a_{k+1})k + (-8a_k + a_{k-1} +$$

- Shift index using $k- >k+1$

$$(-8a_{k+1} + a_k + 16a_{k+2})(k+1)^2 + (2(-8a_{k+1} + a_k + 16a_{k+2})r - 17a_{k+1} + 68a_{k+2})(k+1) + (-$$

- Recursion relation that defines series solution to ODE

$$a_{k+2} = -\frac{k^2a_k - 8k^2a_{k+1} + 2kra_k - 16kra_{k+1} + r^2a_k - 8r^2a_{k+1} + 2ka_k - 33ka_{k+1} + 2ra_k - 33ra_{k+1} - 24a_{k+1}}{4(4k^2+8kr+4r^2+25k+25r+34)}$$

- Recursion relation for $r=0$

$$a_{k+2} = -\frac{k^2a_k - 8k^2a_{k+1} + 2ka_k - 33ka_{k+1} - 24a_{k+1}}{4(4k^2+25k+34)}$$

- Solution for $r=0$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+2} = -\frac{k^2a_k - 8k^2a_{k+1} + 2ka_k - 33ka_{k+1} - 24a_{k+1}}{4(4k^2+25k+34)}, 52a_1 + a_0 = 0\right]$$

- Revert the change of variables $u = x+4$

$$\left[y(x) = \sum_{k=0}^{\infty} a_k (x+4)^k, a_{k+2} = -\frac{k^2a_k - 8k^2a_{k+1} + 2ka_k - 33ka_{k+1} - 24a_{k+1}}{4(4k^2+25k+34)}, 52a_1 + a_0 = 0\right]$$

- Recursion relation for $r = -\frac{9}{4}$

$$a_{k+2} = -\frac{k^2a_k - 8k^2a_{k+1} - \frac{5}{2}ka_k + 3ka_{k+1} + \frac{9}{16}a_k + \frac{39}{4}a_{k+1}}{4(4k^2+7k-2)}$$

- Solution for $r = -\frac{9}{4}$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k-\frac{9}{4}}, a_{k+2} = -\frac{k^2a_k - 8k^2a_{k+1} - \frac{5}{2}ka_k + 3ka_{k+1} + \frac{9}{16}a_k + \frac{39}{4}a_{k+1}}{4(4k^2+7k-2)}, -20a_1 - \frac{5a_0}{4} = 0\right]$$

- Revert the change of variables $u = x+4$

$$\left[y(x) = \sum_{k=0}^{\infty} a_k (x+4)^{k-\frac{9}{4}}, a_{k+2} = -\frac{k^2a_k - 8k^2a_{k+1} - \frac{5}{2}ka_k + 3ka_{k+1} + \frac{9}{16}a_k + \frac{39}{4}a_{k+1}}{4(4k^2+7k-2)}, -20a_1 - \frac{5a_0}{4} = 0\right]$$

- Combine solutions and rename parameters

$$\left[y(x) = \left(\sum_{k=0}^{\infty} a_k (x+4)^k\right) + \left(\sum_{k=0}^{\infty} b_k (x+4)^{k-\frac{9}{4}}\right), a_{k+2} = -\frac{k^2a_k - 8k^2a_{k+1} + 2ka_k - 33ka_{k+1} - 24a_{k+1}}{4(4k^2+25k+34)}, 52a_1$$

2.1.94 Problem 96

Internal problem ID [9266]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 96
Date solved : `Monday, January 27, 2025 at 06:00:45 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$2x^2y'' + 5xy' + (1+x)\,y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.228 (sec)

Writing the ode as

$$2x^2y'' + 5xy' + (1+x)\,y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2x^2 \\ B &= 5x \\ C &= 1+x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-3-8x}{16x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -3-8x \\ t &= 16x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{-3-8x}{16x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.172: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 1 \\ &= 1 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16x^2$. There is a pole at $x = 0$ of order 2. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [2]$$

Attempting to find a solution using case $n = 2$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{2x} - \frac{3}{16x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} E_c &= \{2, 2 + 2\sqrt{1 + 4b}, 2 - 2\sqrt{1 + 4b}\} \\ &= \{1, 2, 3\} \end{aligned}$$

Since the order of r at ∞ is $1 < 2$ then

$$E_\infty = \{1\}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ for case 2 of Kovacic algorithm.

pole c location	pole order	E_c
0	2	$\{1, 2, 3\}$

Order of r at ∞	E_∞
1	$\{1\}$

Using the family $\{e_1, e_2, \dots, e_\infty\}$ given by

$$e_1 = 1, \; e_\infty = 1$$

Gives a non negative integer d (the degree of the polynomial $p(x)$), which is generated using

$$\begin{aligned} d &= \frac{1}{2}\left(e_\infty - \sum_{c\in\Gamma} e_c\right) \\ &= \frac{1}{2}(1 - (1)) \\ &= 0 \end{aligned}$$

We now form the following rational function

$$\begin{aligned} \theta &= \frac{1}{2}\sum_{c\in\Gamma} \frac{e_c}{x-c} \\ &= \frac{1}{2}\left(\frac{1}{(x-(0))}\right) \\ &= \frac{1}{2x} \end{aligned}$$

Now we search for a monic polynomial $p(x)$ of degree $d = 0$ such that

$$p''' + 3\theta p'' + \left(3\theta^2 + 3\theta' - 4r\right) p' + \left(\theta'' + 3\theta\theta' + \theta^3 - 4r\theta - 2r'\right) p = 0 \tag{1A}$$

Since $d = 0$, then letting

$$p = 1 \tag{2A}$$

Substituting p and θ into Eq. (1A) gives

$$0 = 0$$

And solving for p gives

$$p = 1$$

Now that $p(x)$ is found let

$$\begin{aligned} \phi &= \theta + \frac{p'}{p} \\ &= \frac{1}{2x} \end{aligned}$$

Let ω be the solution of

$$\omega^2 - \phi\omega + \left(\frac{1}{2}\phi' + \frac{1}{2}\phi^2 - r\right) = 0$$

Substituting the values for ϕ and r into the above equation gives

$$w^2 - \frac{w}{2x} + \frac{1+8x}{16x^2} = 0$$

Solving for ω gives

$$\omega = \frac{1 + 2\sqrt{2}\,\sqrt{-x}}{4x}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= e^{\int \omega\, dx} \\ &= \mathrm{e}^{\int \frac{1+2\sqrt{2}\,\sqrt{-x}}{4x} dx} \\ &= x^{1/4} \mathrm{e}^{\sqrt{2}\,\sqrt{-x}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{5x}{2x^2}\,dx} \\
&= z_1 e^{-\frac{5\ln(x)}{4}} \\
&= z_1 \left(\frac{1}{x^{5/4}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{\mathrm{e}^{\sqrt{2}\,\sqrt{-x}}}{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{5x}{2x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{5\ln(x)}{2}}}{(y_1)^2}\,dx \\
&= y_1 \left(-\frac{\sqrt{2}\,\sqrt{-x}\left(1-\mathrm{e}^{-2\sqrt{2}\,\sqrt{-x}}\right)}{2\sqrt{x}}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{\mathrm{e}^{\sqrt{2}\,\sqrt{-x}}}{x}\right) + c_2 \left(\frac{\mathrm{e}^{\sqrt{2}\,\sqrt{-x}}}{x}\left(-\frac{\sqrt{2}\,\sqrt{-x}\left(1-\mathrm{e}^{-2\sqrt{2}\,\sqrt{-x}}\right)}{2\sqrt{x}}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$2x^2\left(\frac{d^2}{dx^2}y(x)\right) + 5x\left(\frac{d}{dx}y(x)\right) + (x+1)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{(x+1)y(x)}{2x^2} - \frac{5\left(\frac{d}{dx}y(x)\right)}{2x}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x) + \frac{5\left(\frac{d}{dx}y(x)\right)}{2x} + \frac{(x+1)y(x)}{2x^2} = 0$

☐ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

$\left[P_2(x) = \frac{5}{2x}, P_3(x) = \frac{x+1}{2x^2}\right]$

- ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

  $\left.(x \cdot P_2(x))\right|_{x=0} = \frac{5}{2}$

- ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $\left.(x^2 \cdot P_3(x))\right|_{x=0} = \frac{1}{2}$

- ◦ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $2x^2\left(\frac{d^2}{dx^2}y(x)\right) + 5x\left(\frac{d}{dx}y(x)\right) + (x+1)\,y(x) = 0$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

- □ Rewrite ODE with series expansions

  - ◦ Convert $x^m \cdot y(x)$ to series expansion for $m = 0..1$

    $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

  - ◦ Shift index using $k- >k - m$

    $x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

  - ◦ Convert $x \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion

    $x \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r}$

  - ◦ Convert $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

    $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(1+r)\,(1+2r)\,x^r + \left(\sum_{k=1}^{\infty} \left(a_k(k+r+1)\,(2k+2r+1) + a_{k-1}\right) x^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(1+r)\,(1+2r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \left\{-1, -\frac{1}{2}\right\}$

- Each term in the series must be 0, giving the recursion relation

  $2(k+r+1)\left(k+r+\frac{1}{2}\right)a_k + a_{k-1} = 0$

- Shift index using $k- >k + 1$

  $2(k+2+r)\left(k+\frac{3}{2}+r\right)a_{k+1} + a_k = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+1} = -\frac{a_k}{(k+2+r)(2k+3+2r)}$

- Recursion relation for $r = -1$

  $a_{k+1} = -\frac{a_k}{(k+1)(2k+1)}$

- Solution for $r = -1$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k-1}, a_{k+1} = -\frac{a_k}{(k+1)(2k+1)}\right]$

- Recursion relation for $r = -\frac{1}{2}$

  $a_{k+1} = -\frac{a_k}{\left(k+\frac{3}{2}\right)(2k+2)}$

- Solution for $r = -\frac{1}{2}$

$$\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k-\frac{1}{2}}, a_{k+1} = -\frac{a_k}{\left(k+\frac{3}{2}\right)(2k+2)}\right]$$

- Combine solutions and rename parameters

$$\left[y(x) = \left(\sum_{k=0}^{\infty} a_k x^{k-1}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k-\frac{1}{2}}\right), a_{k+1} = -\frac{a_k}{(k+1)(2k+1)}, b_{k+1} = -\frac{b_k}{\left(k+\frac{3}{2}\right)(2k+2)}\right]$$

2.1.95 Problem 97

Internal problem ID [9267]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 97
Date solved : `Monday, January 27, 2025 at 06:00:46 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$6x^2y'' + x(10-x)\,y' - (2+x)\,y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.375 (sec)

Writing the ode as

$$6x^2y'' + \left(-x^2+10x\right)y' + (-x-2)\,y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 6x^2 \\ B &= -x^2+10x \\ C &= -x-2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2+4x+28}{144x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2+4x+28 \\ t &= 144x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2+4x+28}{144x^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.174: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s)\\ &= 2 - 2\\ &= 0\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 144x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{144} + \frac{1}{36x} + \frac{7}{36x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{7}{36}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{6}\\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{6}\end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i\\ &= \sum_{i=0}^{0} a_i x^i \qquad (8)\end{aligned}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{12} + \frac{1}{6x} + \frac{1}{x^2} - \frac{2}{x^3} - \frac{2}{x^4} + \frac{28}{x^5} - \frac{56}{x^6} - \frac{272}{x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{12}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{12}\end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{144}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned}r &= \frac{s}{t} \\ &= \frac{x^2 + 4x + 28}{144x^2} \\ &= Q + \frac{R}{144x^2} \\ &= \left(\frac{1}{144}\right) + \left(\frac{4x + 28}{144x^2}\right) \\ &= \frac{1}{144} + \frac{4x + 28}{144x^2}\end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is 4. Dividing this by leading coefficient in t which is 144 gives $\frac{1}{36}$. Now b can be found.

$$\begin{aligned}b &= \left(\frac{1}{36}\right) - (0) \\ &= \frac{1}{36}\end{aligned}$$

Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= \frac{1}{12} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{\frac{1}{36}}{\frac{1}{12}} - 0\right) &&= \frac{1}{6} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{\frac{1}{36}}{\frac{1}{12}} - 0\right) &&= -\frac{1}{6}\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2 + 4x + 28}{144x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{7}{6}$	$-\frac{1}{6}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
0	$\frac{1}{12}$	$\frac{1}{6}$	$-\frac{1}{6}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = -\frac{1}{6}$ then

$$\begin{aligned} d &= \alpha_\infty^{-} - \left(\alpha_{c_1}^{-}\right) \\ &= -\frac{1}{6} - \left(-\frac{1}{6}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= -\frac{1}{6x} + (-)\left(\frac{1}{12}\right) \\ &= -\frac{1}{6x} - \frac{1}{12} \\ &= -\frac{2+x}{12x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(-\frac{1}{6x} - \frac{1}{12}\right)(0) + \left(\left(\frac{1}{6x^2}\right) + \left(-\frac{1}{6x} - \frac{1}{12}\right)^2 - \left(\frac{x^2+4x+28}{144x^2}\right)\right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= e^{\int \left(-\frac{1}{6x} - \frac{1}{12}\right) dx} \\ &= \frac{e^{-\frac{x}{12}}}{x^{1/6}} \end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-x^2+10x}{6x^2}\,dx} \\
&= z_1 e^{\frac{x}{12}-\frac{5\ln(x)}{6}} \\
&= z_1 \left(\frac{\mathrm{e}^{\frac{x}{12}}}{x^{5/6}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{1}{x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-x^2+10x}{6x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{\frac{x}{6}-\frac{5\ln(x)}{3}}}{(y_1)^2}\,dx \\
&= y_1 \left(\int \mathrm{e}^{\frac{x}{6}-\frac{5\ln(x)}{3}} x^2 dx\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{1}{x}\right) + c_2 \left(\frac{1}{x}\left(\int \mathrm{e}^{\frac{x}{6}-\frac{5\ln(x)}{3}} x^2 dx\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$6x^2\left(\frac{d^2}{dx^2}y(x)\right) + x(10-x)\left(\frac{d}{dx}y(x)\right) - (x+2)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = \frac{(x+2)y(x)}{6x^2} + \frac{(-10+x)\left(\frac{d}{dx}y(x)\right)}{6x}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x) - \frac{(-10+x)\left(\frac{d}{dx}y(x)\right)}{6x} - \frac{(x+2)y(x)}{6x^2} = 0$

- □ Check to see if $x_0 = 0$ is a regular singular point
  - Define functions

    $\left[P_2(x) = -\frac{-10+x}{6x}, P_3(x) = -\frac{x+2}{6x^2}\right]$

  - $x \cdot P_2(x)$ is analytic at $x = 0$

$(x \cdot P_2(x))\bigg|_{x=0} = \frac{5}{3}$

- ○ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $(x^2 \cdot P_3(x))\bigg|_{x=0} = -\frac{1}{3}$

- ○ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- • Multiply by denominators

  $6x^2\left(\frac{d^2}{dx^2}y(x)\right) - x(-10 + x)\left(\frac{d}{dx}y(x)\right) + (-x - 2)\,y(x) = 0$

- • Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

- □ Rewrite ODE with series expansions

  - ○ Convert $x^m \cdot y(x)$ to series expansion for $m = 0..1$

    $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

  - ○ Shift index using $k- >k - m$

    $x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

  - ○ Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m = 1..2$

    $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k + r)\,x^{k+r-1+m}$

  - ○ Shift index using $k- >k + 1 - m$

    $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k + 1 - m + r)\,x^{k+r}$

  - ○ Convert $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

    $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k + r)\,(k + r - 1)\,x^{k+r}$

  Rewrite ODE with series expansions

  $2a_0(1 + r)\,(-1 + 3r)\,x^r + \left(\sum_{k=1}^{\infty} (2a_k(k + r + 1)\,(3k + 3r - 1) - a_{k-1}(k + r))\,x^{k+r}\right) = 0$

- • $a_0$cannot be 0 by assumption, giving the indicial equation

  $2(1 + r)\,(-1 + 3r) = 0$

- • Values of r that satisfy the indicial equation

  $r \in \left\{-1, \frac{1}{3}\right\}$

- • Each term in the series must be 0, giving the recursion relation

  $6(k + r + 1)\left(k - \frac{1}{3} + r\right)a_k - a_{k-1}(k + r) = 0$

- • Shift index using $k- >k + 1$

  $6(k + 2 + r)\left(k + \frac{2}{3} + r\right)a_{k+1} - a_k(k + r + 1) = 0$

- • Recursion relation that defines series solution to ODE

  $a_{k+1} = \frac{a_k(k+r+1)}{2(k+2+r)(3k+2+3r)}$

- • Recursion relation for $r = -1$

  $a_{k+1} = \frac{a_k k}{2(k+1)(3k-1)}$

- • Solution for $r = -1$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k-1}, a_{k+1} = \frac{a_k k}{2(k+1)(3k-1)}\right]$

- • Recursion relation for $r = \frac{1}{3}$

$$a_{k+1} = \frac{a_k \left(k+\frac{4}{3}\right)}{2\left(k+\frac{7}{3}\right)\left(3k+3\right)}$$

- Solution for $r = \frac{1}{3}$

$$\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{3}}, a_{k+1} = \frac{a_k \left(k+\frac{4}{3}\right)}{2\left(k+\frac{7}{3}\right)\left(3k+3\right)}\right]$$

- Combine solutions and rename parameters

$$\left[y(x) = \left(\sum_{k=0}^{\infty} a_k x^{k-1}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{3}}\right), a_{k+1} = \frac{a_k k}{2(k+1)(3k-1)}, b_{k+1} = \frac{b_k \left(k+\frac{4}{3}\right)}{2\left(k+\frac{7}{3}\right)\left(3k+3\right)}\right]$$

2.1.96 Problem 98

Internal problem ID [9268]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 98
Date solved : `Monday, January 27, 2025 at 06:00:47 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2(3+4x)\,y''+x(11+4x)\,y'-(3+4x)\,y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.316 (sec)

Writing the ode as

$$\left(4x^3+3x^2\right)y''+\left(4x^2+11x\right)y'+(-3-4x)\,y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4x^3+3x^2 \\ B &= 4x^2+11x \\ C &= -3-4x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{48x^2+8x+91}{4\left(4x^2+3x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 48x^2+8x+91 \\ t &= 4\left(4x^2+3x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{48x^2+8x+91}{4\left(4x^2+3x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.176: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(4x^2 + 3x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -\frac{3}{4}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{28}{9\left(x + \frac{3}{4}\right)^2} + \frac{176}{27\left(x + \frac{3}{4}\right)} - \frac{176}{27x} + \frac{91}{36x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{91}{36}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{13}{6} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{7}{6} \end{aligned}$$

For the pole at $x = -\frac{3}{4}$ let b be the coefficient of $\frac{1}{\left(x+\frac{3}{4}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{28}{9}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{7}{3} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{4}{3} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{48x^2 + 8x + 91}{4\left(4x^2 + 3x\right)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{3}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{48x^2 + 8x + 91}{4\left(4x^2 + 3x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{13}{6}$	$-\frac{7}{6}$
$-\frac{3}{4}$	2	0	$\frac{7}{3}$	$-\frac{4}{3}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -\frac{1}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^-\right) \\
&= -\frac{1}{2} - \left(-\frac{5}{2}\right) \\
&= 2
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2} \right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{7}{6x} - \frac{4}{3\left(x+\frac{3}{4}\right)} + (-)(0) \\
&= -\frac{7}{6x} - \frac{4}{3\left(x+\frac{3}{4}\right)} \\
&= \frac{-7-20x}{8x^2+6x}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 2$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x^2 + a_1 x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(2) + 2\left(-\frac{7}{6x} - \frac{4}{3\left(x+\frac{3}{4}\right)}\right)(2x + a_1) + \left(\left(\frac{7}{6x^2} + \frac{4}{3\left(x+\frac{3}{4}\right)^2}\right) + \left(-\frac{7}{6x} - \frac{4}{3\left(x+\frac{3}{4}\right)}\right)^2 - \left(\frac{48x^2 + 8x}{4\left(4x^2 + 3\right.}\right.\right.$$

$$\frac{12a_1 x - 8x + 32a_0 -}{x(3+4x)}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\left\{a_0 = \frac{7}{48}, a_1 = \frac{2}{3}\right\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^2 + \frac{2}{3}x + \frac{7}{48}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \left(x^2 + \frac{2}{3}x + \frac{7}{48}\right) e^{\int \left(-\frac{7}{6x} - \frac{4}{3\left(x+\frac{3}{4}\right)}\right) dx} \\
&= \left(x^2 + \frac{2}{3}x + \frac{7}{48}\right) e^{-\frac{7\ln(x)}{6} - \frac{4\ln(3+4x)}{3}} \\
&= \frac{x^2 + \frac{2}{3}x + \frac{7}{48}}{x^{7/6}(3+4x)^{4/3}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{4x^2+11x}{4x^3+3x^2} \, dx} \\
&= z_1 e^{-\frac{11\ln(x)}{6} + \frac{4\ln(3+4x)}{3}} \\
&= z_1 \left(\frac{(3+4x)^{4/3}}{x^{11/6}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{x^2 + \frac{2}{3}x + \frac{7}{48}}{x^3}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{4x^2+11x}{4x^3+3x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{11\ln(x)}{3}+\frac{8\ln(3+4x)}{3}}}{(y_1)^2}\,dx \\
&= y_1 \left(\int \frac{e^{-\frac{11\ln(x)}{3}+\frac{8\ln(3+4x)}{3}}x^6}{\left(x^2+\frac{2}{3}x+\frac{7}{48}\right)^2}\,dx \right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{x^2+\frac{2}{3}x+\frac{7}{48}}{x^3} \right) + c_2 \left(\frac{x^2+\frac{2}{3}x+\frac{7}{48}}{x^3} \left(\int \frac{e^{-\frac{11\ln(x)}{3}+\frac{8\ln(3+4x)}{3}}x^6}{\left(x^2+\frac{2}{3}x+\frac{7}{48}\right)^2}\,dx \right) \right)
\end{aligned}$$

Will add steps showing solving for IC soon.

- Assume series solution for $y(x)$
  $y(x)=\sum_{k=0}^{\infty}a_kx^{k+r}$
- □ Rewrite ODE with series expansions
  - Convert $x^m\cdot y(x)$ to series expansion for $m=0..1$

$x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- Shift index using $k- >k-m$

  $x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m = 1..2$

  $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1+m}$

- Shift index using $k- >k+1-m$

  $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$

- Convert $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m = 2..3$

  $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-2+m}$

- Shift index using $k- >k+2-m$

  $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(3+r)\,(-1+3r)\, x^r + \left(\sum_{k=1}^{\infty} \left(a_k(k+r+3)\,(3k+3r-1) + 4a_{k-1}(k+r)\,(k-2+r)\right) x^{k+r}\right) =$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(3+r)\,(-1+3r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \left\{-3, \frac{1}{3}\right\}$

- Each term in the series must be 0, giving the recursion relation

  $3\left(k-\frac{1}{3}+r\right)(k+r+3)\, a_k + 4a_{k-1}(k+r)\,(k-2+r) = 0$

- Shift index using $k- >k+1$

  $3\left(k+\frac{2}{3}+r\right)(k+4+r)\, a_{k+1} + 4a_k(k+r+1)\,(k+r-1) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+1} = -\frac{4a_k(k+r+1)(k+r-1)}{(3k+2+3r)(k+4+r)}$

- Recursion relation for $r = -3$; series terminates at $k = 2$

  $a_{k+1} = -\frac{4a_k(k-2)(k-4)}{(3k-7)(k+1)}$

- Apply recursion relation for $k = 0$

  $a_1 = \frac{32a_0}{7}$

- Apply recursion relation for $k = 1$

  $a_2 = \frac{3a_1}{2}$

- Express in terms of a_0

  $a_2 = \frac{48a_0}{7}$

- Terminating series solution of the ODE for $r = -3$. Use reduction of order to find the second

  $y(x) = a_0 \cdot \left(\frac{48}{7}x^2 + \frac{32}{7}x + 1\right)$

- Recursion relation for $r = \frac{1}{3}$

  $a_{k+1} = -\frac{4a_k\left(k+\frac{4}{3}\right)\left(k-\frac{2}{3}\right)}{(3k+3)\left(k+\frac{13}{3}\right)}$

- Solution for $r = \frac{1}{3}$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{3}}, a_{k+1} = -\frac{4a_k\left(k+\frac{4}{3}\right)\left(k-\frac{2}{3}\right)}{(3k+3)\left(k+\frac{13}{3}\right)}\right]$

- Combine solutions and rename parameters

$$\left[y(x) = a_0 \cdot \left(\frac{48}{7}x^2 + \frac{32}{7}x + 1\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{3}}\right), b_{k+1} = -\frac{4b_k\left(k+\frac{4}{3}\right)\left(k-\frac{2}{3}\right)}{(3k+3)\left(k+\frac{13}{3}\right)}\right]$$

Solve

$$2x^2(2+3x)\,y''+x(4+11x)\,y'-(1-x)\,y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.186 (sec)

Writing the ode as

$$\left(6x^3+4x^2\right)y''+\left(11x^2+4x\right)y'+(x-1)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 6x^3+4x^2 \\ B &= 11x^2+4x \\ C &= x-1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{-35}{16\,(2+3x)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -35 \\ t &= 16(2+3x)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(-\frac{35}{16\,(2+3x)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.178: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16(2+3x)^2$. There is a pole at $x = -\frac{2}{3}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{35}{144\left(x + \frac{2}{3}\right)^2}$$

For the pole at $x = -\frac{2}{3}$ let b be the coefficient of $\frac{1}{\left(x+\frac{2}{3}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{35}{144}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{12} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{5}{12} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = -\frac{35}{16\,(2+3x)^2}$$

Since the gcd$(s,t)=1$. This gives $b=-\frac{35}{144}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= \frac{1}{2}+\sqrt{1+4b}=\frac{7}{12} \\
\alpha_\infty^{-} &= \frac{1}{2}-\sqrt{1+4b}=\frac{5}{12}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r=-\frac{35}{16\left(2+3x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
$-\frac{2}{3}$	2	0	$\frac{7}{12}$	$\frac{5}{12}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{7}{12}$	$\frac{5}{12}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-}=\frac{5}{12}$ then

$$
\begin{aligned}
d &= \alpha_\infty^{-}-\left(\alpha_{c_1}^{-}\right) \\
&= \frac{5}{12}-\left(\frac{5}{12}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$
\omega=\sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c+\frac{\alpha_c^{s(c)}}{x-c}\right)+s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1}+\frac{\alpha_{c_1}^{-}}{x-c_1}\right)+(-)[\sqrt{r}]_\infty \\
&= \frac{5}{12\left(x+\frac{2}{3}\right)}+(-)\left(0\right) \\
&= \frac{5}{12\left(x+\frac{2}{3}\right)} \\
&= \frac{5}{8+12x}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p''+2\omega p'+\left(\omega'+\omega^2-r\right)p=0 \tag{1A}
$$

Let

$$
p(x)=1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(\frac{5}{12\left(x+\frac{2}{3}\right)}\right)(0)+\left(\left(-\frac{5}{12\left(x+\frac{2}{3}\right)^{2}}\right)+\left(\frac{5}{12\left(x+\frac{2}{3}\right)}\right)^{2}-\left(-\frac{35}{16\left(2+3x\right)^{2}}\right)\right)=0$$

$$0=0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z''=rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \frac{5}{12\left(x+\frac{2}{3}\right)}dx} \\
&= (2+3x)^{5/12}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{11x^2+4x}{6x^3+4x^2}\,dx} \\
&= z_1 e^{-\frac{5\ln(2+3x)}{12}-\frac{\ln(x)}{2}} \\
&= z_1\left(\frac{1}{(2+3x)^{5/12}\sqrt{x}}\right)
\end{aligned}$$

Which simplifies to

$$y_1=\frac{1}{\sqrt{x}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2=y_1\int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1\int \frac{e^{\int -\frac{11x^2+4x}{6x^3+4x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1\int \frac{e^{-\frac{5\ln(2+3x)}{6}-\ln(x)}}{(y_1)^2}\,dx \\
&= y_1\left(2\,\mathrm{e}^{-\frac{5\ln(2+3x)}{6}-\ln(x)}x(2+3x)\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1y_1+c_2y_2 \\
&= c_1\left(\frac{1}{\sqrt{x}}\right)+c_2\left(\frac{1}{\sqrt{x}}\left(2\,\mathrm{e}^{-\frac{5\ln(2+3x)}{6}-\ln(x)}x(2+3x)\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$2x^2(3x+2)\left(\frac{d^2}{dx^2}y(x)\right)+x(4+11x)\left(\frac{d}{dx}y(x)\right)-(1-x)\,y(x)=0$

- Highest derivative means the order of the ODE is 2

$\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

$\frac{d^2}{dx^2}y(x)=-\frac{(x-1)y(x)}{2(3x+2)x^2}-\frac{(4+11x)\left(\frac{d}{dx}y(x)\right)}{2x(3x+2)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

$\frac{d^2}{dx^2}y(x)+\frac{(4+11x)\left(\frac{d}{dx}y(x)\right)}{2x(3x+2)}+\frac{(x-1)y(x)}{2(3x+2)x^2}=0$

□ Check to see if x_0 is a regular singular point

- ◦ Define functions

$\left[P_2(x)=\frac{4+11x}{2x(3x+2)},P_3(x)=\frac{x-1}{2(3x+2)x^2}\right]$

- ◦ $x\cdot P_2(x)$ is analytic at $x=0$

$\left(x\cdot P_2(x)\right)\Big|_{x=0}=1$

- ◦ $x^2\cdot P_3(x)$ is analytic at $x=0$

$\left(x^2\cdot P_3(x)\right)\Big|_{x=0}=-\frac{1}{4}$

- ◦ $x=0$is a regular singular point

Check to see if x_0 is a regular singular point

$x_0=0$

- Multiply by denominators

$2x^2(3x+2)\left(\frac{d^2}{dx^2}y(x)\right)+x(4+11x)\left(\frac{d}{dx}y(x)\right)+(x-1)\,y(x)=0$

- Assume series solution for $y(x)$

$y(x)=\sum_{k=0}^{\infty}a_kx^{k+r}$

□ Rewrite ODE with series expansions

- ◦ Convert $x^m\cdot y(x)$ to series expansion for $m=0..1$

$x^m\cdot y(x)=\sum_{k=0}^{\infty}a_kx^{k+r+m}$

- ◦ Shift index using $k->k-m$

$x^m\cdot y(x)=\sum_{k=m}^{\infty}a_{k-m}x^{k+r}$

- ◦ Convert $x^m\cdot\left(\frac{d}{dx}y(x)\right)$ to series expansion for $m=1..2$

$x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,x^{k+r-1+m}$

- ◦ Shift index using $k->k+1-m$

$x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,x^{k+r}$

- ◦ Convert $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m=2..3$

$x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,x^{k+r-2+m}$

- ◦ Shift index using $k->k+2-m$

$x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=-2+m}^{\infty}a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$

Rewrite ODE with series expansions

$$a_0(1+2r)(-1+2r)x^r + \left(\sum_{k=1}^{\infty} \left(a_k(2k+2r+1)(2k+2r-1) + a_{k-1}(2k+2r-1)(3k-2+3r\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $(1+2r)(-1+2r) = 0$
- Values of r that satisfy the indicial equation
  $r \in \left\{-\frac{1}{2}, \frac{1}{2}\right\}$
- Each term in the series must be 0, giving the recursion relation
  $4\left(k+r-\frac{1}{2}\right)\left(\left(\frac{3k}{2}+\frac{3r}{2}-1\right)a_{k-1}+a_k\left(k+r+\frac{1}{2}\right)\right) = 0$
- Shift index using $k->k+1$
  $4\left(k+r+\frac{1}{2}\right)\left(\left(\frac{3k}{2}+\frac{1}{2}+\frac{3r}{2}\right)a_k+a_{k+1}\left(k+\frac{3}{2}+r\right)\right) = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+1} = -\frac{(3k+3r+1)a_k}{2k+3+2r}$
- Recursion relation for $r = -\frac{1}{2}$
  $a_{k+1} = -\frac{\left(3k-\frac{1}{2}\right)a_k}{2k+2}$
- Solution for $r = -\frac{1}{2}$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k-\frac{1}{2}}, a_{k+1} = -\frac{\left(3k-\frac{1}{2}\right)a_k}{2k+2}\right]$
- Recursion relation for $r = \frac{1}{2}$
  $a_{k+1} = -\frac{\left(3k+\frac{5}{2}\right)a_k}{2k+4}$
- Solution for $r = \frac{1}{2}$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}, a_{k+1} = -\frac{\left(3k+\frac{5}{2}\right)a_k}{2k+4}\right]$
- Combine solutions and rename parameters
  $\left[y(x) = \left(\sum_{k=0}^{\infty} a_k x^{k-\frac{1}{2}}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{2}}\right), a_{k+1} = -\frac{\left(3k-\frac{1}{2}\right)a_k}{2k+2}, b_{k+1} = -\frac{\left(3k+\frac{5}{2}\right)b_k}{2k+4}\right]$

2.1.98 Problem 100

Internal problem ID [9270]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 100
Date solved : Monday, January 27, 2025 at 06:00:48 PM
CAS classification : [[_2nd_order, _with_linear_symmetries]]

Solve

$$x^2(2+x)\,y''+5x(1-x)\,y'-(2-8x)\,y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.839 (sec)

Writing the ode as

$$x^2(2+x)\,y''+\left(-5x^2+5x\right)y'+(8x-2)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2(2+x) \\ B &= -5x^2+5x \\ C &= 8x-2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{3x^2-126x+21}{4\left(x^2+2x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 3x^2-126x+21 \\ t &= 4\left(x^2+2x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{3x^2-126x+21}{4\left(x^2+2x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.180: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^2+2x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -2$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{147}{16\,(2+x)} + \frac{21}{16x^2} + \frac{285}{16\,(2+x)^2} - \frac{147}{16x}$$

For the pole at $x = -2$ let b be the coefficient of $\frac{1}{(2+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{285}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{19}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{15}{4} \end{aligned}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{21}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{4} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{3x^2 - 126x + 21}{4\left(x^2 + 2x\right)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{3}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{3x^2 - 126x + 21}{4\left(x^2 + 2x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
-2	2	0	$\frac{19}{4}$	$-\frac{15}{4}$
0	2	0	$\frac{7}{4}$	$-\frac{3}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -\frac{1}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^-\right) \\
&= -\frac{1}{2} - \left(-\frac{9}{2}\right) \\
&= 4
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2} \right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{15}{4(2+x)} - \frac{3}{4x} + (-)(0) \\
&= -\frac{15}{4(2+x)} - \frac{3}{4x} \\
&= -\frac{3(3x+1)}{2x(2+x)}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 4$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x^4 + a_3 x^3 + a_2 x^2 + a_1 x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\left(12x^2 + 6xa_3 + 2a_2\right) + 2\left(-\frac{15}{4\,(2+x)} - \frac{3}{4x}\right)\left(4x^3 + 3x^2 a_3 + 2a_2 x + a_1\right) + \left(\left(\frac{15}{4\,(2+x)^2} + \frac{3}{4x^2}\right) + \left(-\frac{}{4\,(2}\right.\right.$$
$$\frac{3(4+a_3)\,x^3 + (8a_2 + 3a_3}{}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\left\{a_0 = \frac{1}{40}, a_1 = \frac{1}{5}, a_2 = \frac{3}{2}, a_3 = -4\right\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^4 - 4x^3 + \frac{3}{2}x^2 + \frac{1}{5}x + \frac{1}{40}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx} \\
&= \left(x^4 - 4x^3 + \frac{3}{2}x^2 + \frac{1}{5}x + \frac{1}{40}\right) \mathrm{e}^{\int \left(-\frac{15}{4(2+x)} - \frac{3}{4x}\right) dx} \\
&= \left(x^4 - 4x^3 + \frac{3}{2}x^2 + \frac{1}{5}x + \frac{1}{40}\right) \mathrm{e}^{-\frac{3\ln(x)}{4} - \frac{15\ln(2+x)}{4}} \\
&= \frac{40x^4 - 160x^3 + 60x^2 + 8x + 1}{40x^{3/4}\,(2+x)^{15/4}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-5x^2+5x}{x^2(2+x)}\, dx} \\
&= z_1 e^{-\frac{5\ln(x)}{4} + \frac{15\ln(2+x)}{4}} \\
&= z_1 \left(\frac{(2+x)^{15/4}}{x^{5/4}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{40x^4 - 160x^3 + 60x^2 + 8x + 1}{40x^2}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-5x^2+5x}{x^2(2+x)}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-\frac{5\ln(x)}{2}+\frac{15\ln(2+x)}{2}}}{(y_1)^2}\, dx \\
&= y_1 \left(\frac{10\sqrt{2+x}\, x^{5/2}\left(8x^5\sqrt{x(2+x)} + 4200\ln\left(\frac{x+\sqrt{x(2+x)}}{x}\right)x^4 - 4200\ln\left(\frac{\sqrt{x(2+x)}-x}{x}\right)x^4 + 328x^4\sqrt{x(2\right.}{} \right.
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{40x^4 - 160x^3 + 60x^2 + 8x + 1}{40x^2}\right) \\
&\quad + c_2 \left(\frac{40x^4 - 160x^3 + 60x^2 + 8x + 1}{40x^2} \left(\frac{10\sqrt{2+x}\, x^{5/2}\left(8x^5\sqrt{x(2+x)} + 4200\ln\left(\frac{x+\sqrt{x(2+x)}}{x}\right)x^4 - 420\right.}{} \right.\right.
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2(x+2)\left(\frac{d^2}{dx^2}y(x)\right) + 5x(1-x)\left(\frac{d}{dx}y(x)\right) - (2-8x)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{2(4x-1)y(x)}{(x+2)x^2} + \frac{5(x-1)\left(\frac{d}{dx}y(x)\right)}{x(x+2)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x) - \frac{5(x-1)\left(\frac{d}{dx}y(x)\right)}{x(x+2)} + \frac{2(4x-1)y(x)}{(x+2)x^2} = 0$

- □ Check to see if x_0 is a regular singular point
  - Define functions

    $\left[P_2(x) = -\frac{5(x-1)}{x(x+2)}, P_3(x) = \frac{2(4x-1)}{(x+2)x^2}\right]$

  - $(x+2)\cdot P_2(x)$ is analytic at $x=-2$

    $\left((x+2)\cdot P_2(x)\right)\Big|_{x=-2} = -\frac{15}{2}$

  - $(x+2)^2\cdot P_3(x)$ is analytic at $x=-2$

    $\left((x+2)^2\cdot P_3(x)\right)\Big|_{x=-2} = 0$

  - $x=-2$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = -2$

- Multiply by denominators

  $x^2(x+2)\left(\frac{d^2}{dx^2}y(x)\right) - 5x(x-1)\left(\frac{d}{dx}y(x)\right) + (8x-2)\,y(x) = 0$

- Change variables using $x = u - 2$ so that the regular singular point is at $u = 0$
  $(u^3 - 4u^2 + 4u)\left(\frac{d^2}{du^2}y(u)\right) + (-5u^2 + 25u - 30)\left(\frac{d}{du}y(u)\right) + (8u - 18)\,y(u) = 0$
- Assume series solution for $y(u)$
  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

□ Rewrite ODE with series expansions

- ○ Convert $u^m \cdot y(u)$ to series expansion for $m = 0..1$
  $u^m \cdot y(u) = \sum_{k=0}^{\infty} a_k u^{k+r+m}$
- ○ Shift index using $k- >k - m$
  $u^m \cdot y(u) = \sum_{k=m}^{\infty} a_{k-m} u^{k+r}$
- ○ Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..2$
  $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k (k + r)\, u^{k+r-1+m}$
- ○ Shift index using $k- >k + 1 - m$
  $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k + 1 - m + r)\, u^{k+r}$
- ○ Convert $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m = 1..3$
  $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k (k + r)\,(k + r - 1)\, u^{k+r-2+m}$
- ○ Shift index using $k- >k + 2 - m$
  $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k + 2 - m + r)\,(k + 1 - m + r)\, u^{k+r}$

  Rewrite ODE with series expansions
  $2a_0 r(-17 + 2r)\, u^{-1+r} + (2a_1(1 + r)\,(-15 + 2r) - a_0(4r^2 - 29r + 18))\, u^r + \left(\sum_{k=1}^{\infty} (2a_{k+1}(k + 1 + r)\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $2r(-17 + 2r) = 0$
- Values of r that satisfy the indicial equation
  $r \in \{0, \frac{17}{2}\}$
- Each term must be 0
  $2a_1(1 + r)\,(-15 + 2r) - a_0(4r^2 - 29r + 18) = 0$
- Each term in the series must be 0, giving the recursion relation
  $(-4a_k + a_{k-1} + 4a_{k+1})\, k^2 + ((-8a_k + 2a_{k-1} + 8a_{k+1})\, r + 29a_k - 8a_{k-1} - 26a_{k+1})\, k + (-4a_k + a_{k-}$
- Shift index using $k- >k + 1$
  $(-4a_{k+1} + a_k + 4a_{k+2})\,(k + 1)^2 + ((-8a_{k+1} + 2a_k + 8a_{k+2})\, r + 29a_{k+1} - 8a_k - 26a_{k+2})\,(k + 1) + ($
- Recursion relation that defines series solution to ODE
  $a_{k+2} = -\frac{k^2 a_k - 4k^2 a_{k+1} + 2kra_k - 8kra_{k+1} + r^2 a_k - 4r^2 a_{k+1} - 6ka_k + 21ka_{k+1} - 6ra_k + 21ra_{k+1} + 8a_k + 7a_{k+1}}{2(2k^2 + 4kr + 2r^2 - 9k - 9r - 26)}$
- Recursion relation for $r = 0$
  $a_{k+2} = -\frac{k^2 a_k - 4k^2 a_{k+1} - 6ka_k + 21ka_{k+1} + 8a_k + 7a_{k+1}}{2(2k^2 - 9k - 26)}$
- Solution for $r = 0$
  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+2} = -\frac{k^2 a_k - 4k^2 a_{k+1} - 6ka_k + 21ka_{k+1} + 8a_k + 7a_{k+1}}{2(2k^2 - 9k - 26)}, -30a_1 - 18a_0 = 0\right]$
- Revert the change of variables $u = x + 2$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k (x + 2)^k, a_{k+2} = -\frac{k^2 a_k - 4k^2 a_{k+1} - 6ka_k + 21ka_{k+1} + 8a_k + 7a_{k+1}}{2(2k^2 - 9k - 26)}, -30a_1 - 18a_0 = 0\right]$
- Recursion relation for $r = \frac{17}{2}$

$$a_{k+2} = -\frac{k^2 a_k - 4k^2 a_{k+1} + 11k a_k - 47k a_{k+1} + \frac{117}{4} a_k - \frac{207}{2} a_{k+1}}{2(2k^2+25k+42)}$$

- Solution for $r = \frac{17}{2}$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+\frac{17}{2}}, a_{k+2} = -\frac{k^2 a_k - 4k^2 a_{k+1} + 11k a_k - 47k a_{k+1} + \frac{117}{4} a_k - \frac{207}{2} a_{k+1}}{2(2k^2+25k+42)}, 38a_1 - \frac{121a_0}{2} = 0\right]$$

- Revert the change of variables $u = x + 2$

$$\left[y(x) = \sum_{k=0}^{\infty} a_k (x+2)^{k+\frac{17}{2}}, a_{k+2} = -\frac{k^2 a_k - 4k^2 a_{k+1} + 11k a_k - 47k a_{k+1} + \frac{117}{4} a_k - \frac{207}{2} a_{k+1}}{2(2k^2+25k+42)}, 38a_1 - \frac{121a_0}{2} = 0\right]$$

- Combine solutions and rename parameters

$$\left[y(x) = \left(\sum_{k=0}^{\infty} a_k (x+2)^k\right) + \left(\sum_{k=0}^{\infty} b_k (x+2)^{k+\frac{17}{2}}\right), a_{k+2} = -\frac{k^2 a_k - 4k^2 a_{k+1} - 6k a_k + 21k a_{k+1} + 8a_k + 7a_{k+1}}{2(2k^2-9k-26)}, \right.$$

2.1.99 Problem 101

Internal problem ID [9271]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 101
Date solved : `Monday, January 27, 2025 at 06:00:49 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$8x^2\left(-x^2+1\right)y''+2x\left(-13x^2+1\right)y'+\left(-9x^2+1\right)y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.335 (sec)

Writing the ode as

$$\left(-8x^4+8x^2\right)y''+\left(-26x^3+2x\right)y'+\left(-9x^2+1\right)y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A &= -8x^4+8x^2\\ B &= -26x^3+2x\\ C &= -9x^2+1\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned}r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2}\end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{-7x^4-26x^2-15}{64\left(x^3-x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned}s &= -7x^4-26x^2-15\\ t &= 64\left(x^3-x\right)^2\end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{-7x^4-26x^2-15}{64\left(x^3-x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.182: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 4 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 64(x^3 - x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = 1$ of order 2. There is a pole at $x = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{15}{64x^2} + \frac{1}{4x - 4} - \frac{3}{16\,(x + 1)^2} - \frac{3}{16\,(x - 1)^2} - \frac{1}{4\,(x + 1)}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{15}{64}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{5}{8} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{3}{8} \end{aligned}$$

For the pole at $x = 1$ let b be the coefficient of $\frac{1}{(x-1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{3}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{4} \end{aligned}$$

For the pole at $x = -1$ let b be the coefficient of $\frac{1}{(x+1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{4} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{4}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = \frac{-7x^4 - 26x^2 - 15}{64\,(x^3 - x)^2}
$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{7}{64}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{8} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{8}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{-7x^4 - 26x^2 - 15}{64\,(x^3 - x)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{5}{8}$	$\frac{3}{8}$
1	2	0	$\frac{3}{4}$	$\frac{1}{4}$
-1	2	0	$\frac{3}{4}$	$\frac{1}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{7}{8}$	$\frac{1}{8}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{7}{8}$ then

$$
\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^- + \alpha_{c_2}^- + \alpha_{c_3}^-\right) \\
&= \frac{7}{8} - \left(\frac{7}{8}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

Substituting the above values in the above results in

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2}\right) + \left((-)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^-}{x-c_3}\right) + (+)[\sqrt{r}]_\infty \\
&= \frac{3}{8x} + \frac{1}{4x-4} + \frac{1}{4x+4} + (0) \\
&= \frac{3}{8x} + \frac{1}{4x-4} + \frac{1}{4x+4} \\
&= \frac{7x^2-3}{8x^3-8x}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{3}{8x} + \frac{1}{4x-4} + \frac{1}{4x+4}\right)(0) + \left(\left(-\frac{3}{8x^2} - \frac{1}{4(x-1)^2} - \frac{1}{4(x+1)^2}\right) + \left(\frac{3}{8x} + \frac{1}{4x-4} + \frac{1}{4x+4}\right)^2\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= e^{\int \left(\frac{3}{8x} + \frac{1}{4x-4} + \frac{1}{4x+4}\right) dx} \\
&= x^{3/8}(x+1)^{1/4}(x-1)^{1/4}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-26x^3+2x}{-8x^4+8x^2}\, dx} \\
&= z_1 e^{-\frac{\ln(x)}{8} - \frac{3\ln(x+1)}{4} - \frac{3\ln(x-1)}{4}} \\
&= z_1 \left(\frac{1}{x^{1/8}(x+1)^{3/4}(x-1)^{3/4}}\right)
\end{aligned}
$$

Which simplifies to

$$y_1 = \frac{x^{1/4}(x^2-1)^{1/4}}{(x+1)^{3/4}(x-1)^{3/4}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-26x^3+2x}{-8x^4+8x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-\frac{\ln(x)}{4} - \frac{3\ln(x+1)}{2} - \frac{3\ln(x-1)}{2}}}{(y_1)^2}\, dx \\
&= y_1 \left(\int \frac{e^{-\frac{\ln(x)}{4} - \frac{3\ln(x+1)}{2} - \frac{3\ln(x-1)}{2}}(x+1)^{3/2}(x-1)^{3/2}}{\sqrt{x}\,\sqrt{x^2-1}}\, dx\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{x^{1/4}(x^2-1)^{1/4}}{(x+1)^{3/4}(x-1)^{3/4}}\right) + c_2\left(\frac{x^{1/4}(x^2-1)^{1/4}}{(x+1)^{3/4}(x-1)^{3/4}}\left(\int \frac{e^{-\frac{\ln(x)}{4}-\frac{3\ln(x+1)}{2}-\frac{3\ln(x-1)}{2}}(x+1)^{3/2}(x-1)^{3/2}}{\sqrt{x}\sqrt{x^2-1}} dx
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$8x^2(-x^2+1)\left(\frac{d^2}{dx^2}y(x)\right)+2x(-13x^2+1)\left(\frac{d}{dx}y(x)\right)+(-9x^2+1)y(x)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$
- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x)=-\frac{(9x^2-1)y(x)}{8(x^2-1)x^2}-\frac{(13x^2-1)\left(\frac{d}{dx}y(x)\right)}{4x(x^2-1)}$
- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x)+\frac{(13x^2-1)\left(\frac{d}{dx}y(x)\right)}{4x(x^2-1)}+\frac{(9x^2-1)y(x)}{8(x^2-1)x^2}=0$

☐ Check to see if x_0 is a regular singular point

- ◦ Define functions

  $\left[P_2(x)=\frac{13x^2-1}{4x(x^2-1)}, P_3(x)=\frac{9x^2-1}{8(x^2-1)x^2}\right]$
- ◦ $(x+1)\cdot P_2(x)$ is analytic at $x=-1$

  $\left((x+1)\cdot P_2(x)\right)\Big|_{x=-1}=\frac{3}{2}$
- ◦ $(x+1)^2\cdot P_3(x)$ is analytic at $x=-1$

  $\left((x+1)^2\cdot P_3(x)\right)\Big|_{x=-1}=0$
- ◦ $x=-1$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=-1$

- Multiply by denominators

  $8(x^2-1)x^2\left(\frac{d^2}{dx^2}y(x)\right)+2x(13x^2-1)\left(\frac{d}{dx}y(x)\right)+(9x^2-1)y(x)=0$
- Change variables using $x=u-1$ so that the regular singular point is at $u=0$

  $(8u^4-32u^3+40u^2-16u)\left(\frac{d^2}{du^2}y(u)\right)+(26u^3-78u^2+76u-24)\left(\frac{d}{du}y(u)\right)+(9u^2-18u+8)y$
- Assume series solution for $y(u)$

  $y(u)=\sum_{k=0}^{\infty} a_k u^{k+r}$

☐ Rewrite ODE with series expansions

- ◦ Convert $u^m\cdot y(u)$ to series expansion for $m=0..2$

  $u^m\cdot y(u)=\sum_{k=0}^{\infty} a_k u^{k+r+m}$
- ◦ Shift index using $k->k-m$

  $u^m\cdot y(u)=\sum_{k=m}^{\infty} a_{k-m} u^{k+r}$
- ◦ Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..3$

$$u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,u^{k+r-1+m}$$

- Shift index using $k->k+1-m$

$$u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,u^{k+r}$$

- Convert $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m=1..4$

$$u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,u^{k+r-2+m}$$

- Shift index using $k->k+2-m$

$$u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=-2+m}^{\infty}a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,u^{k+r}$$

Rewrite ODE with series expansions

$$-8a_0r(1+2r)\,u^{-1+r}+(-8a_1(1+r)\,(3+2r)+4a_0(1+2r)\,(2+5r))\,u^r+(-8a_2(2+r)\,(5+2r)+$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $-8r(1+2r)=0$
- Values of r that satisfy the indicial equation
  $r\in\left\{0,-\frac{1}{2}\right\}$
- The coefficients of each power of u must be 0
  $[-8a_1(1+r)\,(3+2r)+4a_0(1+2r)\,(2+5r)=0,-8a_2(2+r)\,(5+2r)+4a_1(3+2r)\,(7+5r)-2a$
- Solve for the dependent coefficient(s)
  $\left\{a_1=\frac{a_0(10r^2+9r+2)}{2(2r^2+5r+3)},a_2=\frac{a_0(34r^3+76r^2+41r+5)}{4(2r^3+11r^2+19r+10)}\right\}$
- Each term in the series must be 0, giving the recursion relation
  $8(5a_k+a_{k-2}-4a_{k-1}-2a_{k+1})\,k^2+2(8(5a_k+a_{k-2}-4a_{k-1}-2a_{k+1})\,r+18a_k-7a_{k-2}+9a_{k-1}-2$
- Shift index using $k->k+2$
  $8(5a_{k+2}+a_k-4a_{k+1}-2a_{k+3})\,(k+2)^2+2(8(5a_{k+2}+a_k-4a_{k+1}-2a_{k+3})\,r+18a_{k+2}-7a_k+9a_k$
- Recursion relation that defines series solution to ODE
  $a_{k+3}=\frac{8k^2a_k-32k^2a_{k+1}+40k^2a_{k+2}+16kra_k-64kra_{k+1}+80kra_{k+2}+8r^2a_k-32r^2a_{k+1}+40r^2a_{k+2}+18ka_k-110ka_{k+1}+196ka_{k+2}+}{8(2k^2+4kr+2r^2+13k+13r+21)}$
- Recursion relation for $r=0$
  $a_{k+3}=\frac{8k^2a_k-32k^2a_{k+1}+40k^2a_{k+2}+18ka_k-110ka_{k+1}+196ka_{k+2}+9a_k-96a_{k+1}+240a_{k+2}}{8(2k^2+13k+21)}$
- Solution for $r=0$
  $\left[y(u)=\sum_{k=0}^{\infty}a_ku^k,a_{k+3}=\frac{8k^2a_k-32k^2a_{k+1}+40k^2a_{k+2}+18ka_k-110ka_{k+1}+196ka_{k+2}+9a_k-96a_{k+1}+240a_{k+2}}{8(2k^2+13k+21)},a_1=\frac{a_0}{3},a\right.$
- Revert the change of variables $u=x+1$
  $\left[y(x)=\sum_{k=0}^{\infty}a_k(x+1)^k,a_{k+3}=\frac{8k^2a_k-32k^2a_{k+1}+40k^2a_{k+2}+18ka_k-110ka_{k+1}+196ka_{k+2}+9a_k-96a_{k+1}+240a_{k+2}}{8(2k^2+13k+21)},a_1=\right.$
- Recursion relation for $r=-\frac{1}{2}$
  $a_{k+3}=\frac{8k^2a_k-32k^2a_{k+1}+40k^2a_{k+2}+10ka_k-78ka_{k+1}+156ka_{k+2}+2a_k-49a_{k+1}+152a_{k+2}}{8(2k^2+11k+15)}$
- Solution for $r=-\frac{1}{2}$
  $\left[y(u)=\sum_{k=0}^{\infty}a_ku^{k-\frac{1}{2}},a_{k+3}=\frac{8k^2a_k-32k^2a_{k+1}+40k^2a_{k+2}+10ka_k-78ka_{k+1}+156ka_{k+2}+2a_k-49a_{k+1}+152a_{k+2}}{8(2k^2+11k+15)},a_1=0,a\right.$
- Revert the change of variables $u=x+1$
  $\left[y(x)=\sum_{k=0}^{\infty}a_k(x+1)^{k-\frac{1}{2}},a_{k+3}=\frac{8k^2a_k-32k^2a_{k+1}+40k^2a_{k+2}+10ka_k-78ka_{k+1}+156ka_{k+2}+2a_k-49a_{k+1}+152a_{k+2}}{8(2k^2+11k+15)},a_1\right.$
- Combine solutions and rename parameters
  $\left[y(x)=\left(\sum_{k=0}^{\infty}a_k(x+1)^k\right)+\left(\sum_{k=0}^{\infty}b_k(x+1)^{k-\frac{1}{2}}\right),a_{k+3}=\frac{8k^2a_k-32k^2a_{k+1}+40k^2a_{k+2}+18ka_k-110ka_{k+1}+196ka}{8(2k^2+13k+21)}\right.$

$$y(x) \to \exp\left(\int_1^x \frac{3-7K[1]^2}{8K[1]-8K[1]^3}dK[1] - \frac{1}{2}\int_1^x \frac{1-13K[2]^2}{4K[2]-4K[2]^3}dK[2]\right)\left(c_2\int_1^x \exp\left(-2\int_1^{K[3]} \frac{3-7K[1]^2}{8K[1]-8K[1]^3}dK[1]\right)dK[3] + c_1\right)$$

2.1.100 Problem 102

Internal problem ID [9272]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 102
Date solved : `Monday, January 27, 2025 at 06:00:50 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2\left(x^2+1\right)y''-2x\left(-x^2+2\right)y'+4y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.357 (sec)

Writing the ode as

$$\left(x^4+x^2\right)y''+\left(2x^3-4x\right)y'+4y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A&=x^4+x^2\\ B&=2x^3-4x\\ C&=4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r&=\frac{s}{t}\\ &=\frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{-x^2+2}{\left(x^3+x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s&=-x^2+2\\ t&=\left(x^3+x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{-x^2+2}{\left(x^3+x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.184: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 2 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (x^3 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = i$ of order 2. There is a pole at $x = -i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{3}{4(x - i)^2} + \frac{3}{4(x + i)^2} + \frac{7i}{4(x - i)} - \frac{7i}{4(x + i)} + \frac{2}{x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -1 \end{aligned}$$

For the pole at $x = i$ let b be the coefficient of $\frac{1}{(x-i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{1}{2} \end{aligned}$$

For the pole at $x = -i$ let b be the coefficient of $\frac{1}{(x+i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}
$$

Since the order of r at ∞ is $4 > 2$ then

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= 0 \\
\alpha_\infty^- &= 1
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{-x^2+2}{(x^3+x)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	2	-1
i	2	0	$\frac{3}{2}$	$-\frac{1}{2}$
$-i$	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$ then

$$
\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^+ + \alpha_{c_2}^- + \alpha_{c_3}^-\right) \\
&= 1 - (1) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2} \right) + \left((-)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^-}{x-c_3} \right) + (-)[\sqrt{r}]_\infty \\
&= \frac{2}{x} - \frac{1}{2(x-i)} - \frac{1}{2(x+i)} + (-)(0) \\
&= \frac{2}{x} - \frac{1}{2(x-i)} - \frac{1}{2(x+i)} \\
&= \frac{x^2+2}{x^3+x}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p''+2\omega p'+\left(\omega'+\omega^2-r\right)p=0 \tag{1A}$$

Let

$$p(x)=1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(\frac{2}{x}-\frac{1}{2(x-i)}-\frac{1}{2(x+i)}\right)(0)+\left(\left(-\frac{2}{x^2}+\frac{1}{2(x-i)^2}+\frac{1}{2(x+i)^2}\right)+\left(\frac{2}{x}-\frac{1}{2(x-i)}-\frac{1}{2(x+\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z''=rz$ is

$$\begin{aligned}
z_1(x) &= pe^{\int \omega\,dx}\\
&= \mathrm{e}^{\int \left(\frac{2}{x}-\frac{1}{2(x-i)}-\frac{1}{2(x+i)}\right)dx}\\
&= \frac{x^2}{\sqrt{x^2+1}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}\\
&= z_1 e^{-\int \frac{1}{2}\frac{2x^3-4x}{x^4+x^2}\,dx}\\
&= z_1 e^{-\frac{3\ln\left(x^2+1\right)}{2}+2\ln(x)}\\
&= z_1\left(\frac{x^2}{\left(x^2+1\right)^{3/2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1=\frac{x^4}{\left(x^2+1\right)^2}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2=y_1\int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1\int \frac{e^{\int -\frac{2x^3-4x}{x^4+x^2}\,dx}}{\left(y_1\right)^2}\,dx\\
&= y_1\int \frac{e^{-3\ln(x^2+1)+4\ln(x)}}{\left(y_1\right)^2}\,dx\\
&= y_1\left(-\frac{\left(3x^2+1\right)\left(x^2+1\right)^3\mathrm{e}^{-3\ln(x^2+1)+4\ln(x)}}{3x^7}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1y_1+c_2y_2\\
&= c_1\left(\frac{x^4}{\left(x^2+1\right)^2}\right)+c_2\left(\frac{x^4}{\left(x^2+1\right)^2}\left(-\frac{\left(3x^2+1\right)\left(x^2+1\right)^3\mathrm{e}^{-3\ln(x^2+1)+4\ln(x)}}{3x^7}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2(x^2+1)\left(\frac{d^2}{dx^2}y(x)\right) - 2x(-x^2+2)\left(\frac{d}{dx}y(x)\right) + 4y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{4y(x)}{x^2(x^2+1)} - \frac{2(x^2-2)\left(\frac{d}{dx}y(x)\right)}{x(x^2+1)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x) + \frac{2(x^2-2)\left(\frac{d}{dx}y(x)\right)}{x(x^2+1)} + \frac{4y(x)}{x^2(x^2+1)} = 0$

☐ Check to see if x_0 is a regular singular point

- ◦ Define functions

  $\left[P_2(x) = \frac{2(x^2-2)}{x(x^2+1)}, P_3(x) = \frac{4}{x^2(x^2+1)}\right]$

- ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

  $(x \cdot P_2(x))\Big|_{x=0} = -4$

- ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $(x^2 \cdot P_3(x))\Big|_{x=0} = 4$

- ◦ $x = 0$is a regular singular point

Check to see if x_0 is a regular singular point

$x_0 = 0$

- Multiply by denominators

  $x^2(x^2+1)\left(\frac{d^2}{dx^2}y(x)\right) + 2x(x^2-2)\left(\frac{d}{dx}y(x)\right) + 4y(x) = 0$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

- ◦ Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m = 1..3$

  $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1+m}$

- ◦ Shift index using $k->k+1-m$

  $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$

- ◦ Convert $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m = 2..4$

  $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, x^{k+r-2+m}$

- ◦ Shift index using $k->k+2-m$

  $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\, x^{k+r}$

Rewrite ODE with series expansions

$a_0(-1+r)(-4+r)\, x^r + a_1 r(-3+r)\, x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(k+r-1)(k+r-4) + a_{k-2}(k-2+r)(k\right.\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-1+r)(-4+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{1, 4\}$

- Each term must be 0
  $a_1 r(-3+r) = 0$
- Solve for the dependent coefficient(s)
  $a_1 = 0$
- Each term in the series must be 0, giving the recursion relation
  $(k+r-1)\left(a_k(k+r-4) + a_{k-2}(k-2+r)\right) = 0$
- Shift index using $k->k+2$
  $(k+r+1)\left(a_{k+2}(k-2+r) + a_k(k+r)\right) = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+2} = -\frac{a_k(k+r)}{k-2+r}$
- Recursion relation for $r = 1$
  $a_{k+2} = -\frac{a_k(k+1)}{k-1}$
- Solution for $r = 1$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+1}, a_{k+2} = -\frac{a_k(k+1)}{k-1}, a_1 = 0\right]$
- Recursion relation for $r = 4$
  $a_{k+2} = -\frac{a_k(k+4)}{k+2}$
- Solution for $r = 4$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+4}, a_{k+2} = -\frac{a_k(k+4)}{k+2}, a_1 = 0\right]$
- Combine solutions and rename parameters
  $\left[y(x) = \left(\sum_{k=0}^{\infty} a_k x^{k+1}\right) + \left(\sum_{k=0}^{\infty} b_k x^{4+k}\right), a_{k+2} = -\frac{a_k(k+1)}{k-1}, a_1 = 0, b_{k+2} = -\frac{b_k(4+k)}{k+2}, b_1 = 0\right]$

2.1.101 Problem 103

Internal problem ID [9273]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 103
Date solved : `Monday, January 27, 2025 at 06:00:51 PM`
CAS classification : `[[_2nd_order, _exact, _linear, _homogeneous]]`

Solve

$$x\left(x^{2}+3\right) y''+\left(-x^{2}+2\right) y'-8 x y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.277 (sec)

Writing the ode as

$$\left(x^{3}+3 x\right) y''+\left(-x^{2}+2\right) y'-8 x y=0 \tag{1}$$

$$A y''+B y'+C y=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^{3}+3 x \\ B &= -x^{2}+2 \\ C &= -8 x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=y e^{\int \frac{B}{2 A} d x}$$

Then (2) becomes

$$z''(x)=r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2 A B'-2 B A'+B^{2}-4 A C}{4 A^{2}} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r=\frac{35 x^{4}+74 x^{2}-8}{4\left(x^{3}+3 x\right)^{2}} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 35 x^{4}+74 x^{2}-8 \\ t &= 4\left(x^{3}+3 x\right)^{2} \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{35 x^{4}+74 x^{2}-8}{4\left(x^{3}+3 x\right)^{2}}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.186: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 4 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^3+3x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = i\sqrt{3}$ of order 2. There is a pole at $x = -i\sqrt{3}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{85}{144\left(x - i\sqrt{3}\right)^2} + \frac{85}{144\left(x + i\sqrt{3}\right)^2} - \frac{187 i\sqrt{3}}{144\left(x - i\sqrt{3}\right)} + \frac{187 i\sqrt{3}}{144\left(x + i\sqrt{3}\right)} - \frac{2}{9x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{2}{9}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{2}{3} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{3} \end{aligned}$$

For the pole at $x = i\sqrt{3}$ let b be the coefficient of $\frac{1}{\left(x-i\sqrt{3}\right)^{2}}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{85}{144}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0\\
\alpha_c^{+} &= \frac{1}{2} + \sqrt{1+4b} = \frac{17}{12}\\
\alpha_c^{-} &= \frac{1}{2} - \sqrt{1+4b} = -\frac{5}{12}
\end{aligned}
$$

For the pole at $x = -i\sqrt{3}$ let b be the coefficient of $\frac{1}{\left(x+i\sqrt{3}\right)^{2}}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{85}{144}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0\\
\alpha_c^{+} &= \frac{1}{2} + \sqrt{1+4b} = \frac{17}{12}\\
\alpha_c^{-} &= \frac{1}{2} - \sqrt{1+4b} = -\frac{5}{12}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = \frac{35x^4 + 74x^2 - 8}{4\left(x^3+3x\right)^2}
$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{35}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0\\
\alpha_\infty^{+} &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{2}\\
\alpha_\infty^{-} &= \frac{1}{2} - \sqrt{1+4b} = -\frac{5}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{35x^4 + 74x^2 - 8}{4\left(x^3+3x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{2}{3}$	$\frac{1}{3}$
$i\sqrt{3}$	2	0	$\frac{17}{12}$	$-\frac{5}{12}$
$-i\sqrt{3}$	2	0	$\frac{17}{12}$	$-\frac{5}{12}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{7}{2}$	$-\frac{5}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{+} = \frac{7}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^{+} - \left(\alpha_{c_1}^{+} + \alpha_{c_2}^{+} + \alpha_{c_3}^{+}\right)\\
&= \frac{7}{2} - \left(\frac{7}{2}\right)\\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x-c_1} \right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{+}}{x-c_2} \right) + \left((+)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^{+}}{x-c_3} \right) + (+)[\sqrt{r}]_\infty \\
&= \frac{2}{3x} + \frac{17}{12\left(x-i\sqrt{3}\right)} + \frac{17}{12\left(x+i\sqrt{3}\right)} + (0) \\
&= \frac{2}{3x} + \frac{17}{12\left(x-i\sqrt{3}\right)} + \frac{17}{12\left(x+i\sqrt{3}\right)} \\
&= \frac{2}{3x} + \frac{17x}{6x^2+18}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{2}{3x} + \frac{17}{12\left(x-i\sqrt{3}\right)} + \frac{17}{12\left(x+i\sqrt{3}\right)} \right)(0) + \left(\left(-\frac{2}{3x^2} - \frac{17}{12\left(x-i\sqrt{3}\right)^2} - \frac{17}{12\left(x+i\sqrt{3}\right)^2} \right) + \left(\frac{2}{3x}\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(\frac{2}{3x} + \frac{17}{12\left(x-i\sqrt{3}\right)} + \frac{17}{12\left(x+i\sqrt{3}\right)} \right) dx} \\
&= \left(x^2+3\right)^{17/12} x^{2/3}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-x^2+2}{x^3+3x}\, dx} \\
&= z_1 e^{\frac{5\ln\left(x^2+3\right)}{12} - \frac{\ln(x)}{3}} \\
&= z_1 \left(\frac{\left(x^2+3\right)^{5/12}}{x^{1/3}} \right)
\end{aligned}$$

Which simplifies to

$$y_1 = \left(x^2+3\right)^{11/6} x^{1/3}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-x^2+2}{x^3+3x}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{\frac{5\ln(x^2+3)}{6}-\frac{2\ln(x)}{3}}}{(y_1)^2}\,dx \\
&= y_1 \left(-\frac{x^{1/3}(8x^4+44x^2+55)\,\mathrm{e}^{\frac{5\ln(x^2+3)}{6}-\frac{2\ln(x)}{3}}}{55\,(x^2+3)^{8/3}}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\left(x^2+3\right)^{11/6} x^{1/3}\right) + c_2\left(\left(x^2+3\right)^{11/6} x^{1/3}\left(-\frac{x^{1/3}(8x^4+44x^2+55)\,\mathrm{e}^{\frac{5\ln(x^2+3)}{6}-\frac{2\ln(x)}{3}}}{55\,(x^2+3)^{8/3}}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x(x^2+3)\left(\frac{d^2}{dx^2}y(x)\right)+(-x^2+2)\left(\frac{d}{dx}y(x)\right)-8xy(x)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x)=\frac{8y(x)}{x^2+3}+\frac{(x^2-2)\left(\frac{d}{dx}y(x)\right)}{x(x^2+3)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x)-\frac{(x^2-2)\left(\frac{d}{dx}y(x)\right)}{x(x^2+3)}-\frac{8y(x)}{x^2+3}=0$

☐ Check to see if x_0 is a regular singular point

- ∘ Define functions

  $\left[P_2(x)=-\frac{x^2-2}{x(x^2+3)}, P_3(x)=-\frac{8}{x^2+3}\right]$

- ∘ $x\cdot P_2(x)$ is analytic at $x=0$

  $\left.(x\cdot P_2(x))\right|_{x=0}=\frac{2}{3}$

- ∘ $x^2\cdot P_3(x)$ is analytic at $x=0$

  $\left.(x^2\cdot P_3(x))\right|_{x=0}=0$

- ∘ $x=0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=0$

- Multiply by denominators

  $x(x^2+3)\left(\frac{d^2}{dx^2}y(x)\right)+(-x^2+2)\left(\frac{d}{dx}y(x)\right)-8xy(x)=0$

- Assume series solution for $y(x)$

  $y(x)=\sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $x \cdot y(x)$ to series expansion

$$x \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+1}$$

- Shift index using $k->k-1$

$$x \cdot y(x) = \sum_{k=1}^{\infty} a_{k-1} x^{k+r}$$

- Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m = 0..2$

$$x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1+m}$$

- Shift index using $k->k+1-m$

$$x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$$

- Convert $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m = 1..3$

$$x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, x^{k+r-2+m}$$

- Shift index using $k->k+2-m$

$$x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0 r(-1+3r)\, x^{-1+r} + a_1(1+r)(2+3r)\, x^r + \left(\sum_{k=1}^{\infty} (a_{k+1}(k+r+1)(3k+2+3r) + a_{k-1}(k+r+1$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $r(-1+3r) = 0$
- Values of r that satisfy the indicial equation
  $r \in \left\{0, \frac{1}{3}\right\}$
- Each term must be 0
  $a_1(1+r)(2+3r) = 0$
- Each term in the series must be 0, giving the recursion relation
  $(k+r+1)\left(a_{k-1}(k-5+r) + 3\left(k+r+\frac{2}{3}\right)a_{k+1}\right) = 0$
- Shift index using $k->k+1$
  $(k+r+2)\left(a_k(k+r-4) + 3\left(k+\frac{5}{3}+r\right)a_{k+2}\right) = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+2} = -\frac{a_k(k+r-4)}{3k+5+3r}$
- Recursion relation for $r = 0$; series terminates at $k = 4$
  $a_{k+2} = -\frac{a_k(k-4)}{3k+5}$
- Solution for $r = 0$
  $$\left[y(x) = \sum_{k=0}^{\infty} a_k x^k, a_{k+2} = -\frac{a_k(k-4)}{3k+5}, 2a_1 = 0\right]$$
- Recursion relation for $r = \frac{1}{3}$
  $a_{k+2} = -\frac{a_k\left(k-\frac{11}{3}\right)}{3k+6}$
- Solution for $r = \frac{1}{3}$
  $$\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{3}}, a_{k+2} = -\frac{a_k\left(k-\frac{11}{3}\right)}{3k+6}, 4a_1 = 0\right]$$
- Combine solutions and rename parameters
  $$\left[y(x) = \left(\sum_{k=0}^{\infty} a_k x^k\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{3}}\right), a_{k+2} = -\frac{a_k(-4+k)}{3k+5}, 2a_1 = 0, b_{k+2} = -\frac{b_k\left(k-\frac{11}{3}\right)}{3k+6}, 4b_1 = 0\right]$$

2.1.102 Problem 104

Internal problem ID [9274]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 104
Date solved : `Monday, January 27, 2025 at 06:00:52 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$4x^2\left(-x^2+1\right)y''+x\left(-19x^2+7\right)y'-\left(14x^2+1\right)y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.314 (sec)

Writing the ode as

$$\left(-4x^4+4x^2\right)y''+\left(-19x^3+7x\right)y'+\left(-14x^2-1\right)y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= -4x^4+4x^2 \\ B &= -19x^3+7x \\ C &= -14x^2-1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{-15x^4-42x^2+9}{64\left(x^3-x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -15x^4-42x^2+9 \\ t &= 64\left(x^3-x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{-15x^4-42x^2+9}{64\left(x^3-x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.188: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 4 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 64(x^3 - x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = 1$ of order 2. There is a pole at $x = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{3}{16\,(x-1)^2} - \frac{3}{16\,(x+1)^2} + \frac{9}{64x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{9}{64}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{9}{8} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{8} \end{aligned}$$

For the pole at $x = 1$ let b be the coefficient of $\frac{1}{(x-1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{4} \end{aligned}$$

For the pole at $x = -1$ let b be the coefficient of $\frac{1}{(x+1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{4} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{4}
\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{-15x^4 - 42x^2 + 9}{64\,(x^3 - x)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{15}{64}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{8} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{3}{8}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{-15x^4 - 42x^2 + 9}{64\,(x^3 - x)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{9}{8}$	$-\frac{1}{8}$
1	2	0	$\frac{3}{4}$	$\frac{1}{4}$
-1	2	0	$\frac{3}{4}$	$\frac{1}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{5}{8}$	$\frac{3}{8}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{3}{8}$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^- + \alpha_{c_3}^-\right) \\
&= \frac{3}{8} - \left(\frac{3}{8}\right) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2}\right) + \left((-)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^-}{x-c_3}\right) + (-)[\sqrt{r}]_\infty \\ &= -\frac{1}{8x} + \frac{1}{4x-4} + \frac{1}{4x+4} + (-)(0) \\ &= -\frac{1}{8x} + \frac{1}{4x-4} + \frac{1}{4x+4} \\ &= \frac{3x^2+1}{8x^3-8x}\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{8x} + \frac{1}{4x-4} + \frac{1}{4x+4}\right)(0) + \left(\left(\frac{1}{8x^2} - \frac{1}{4(x-1)^2} - \frac{1}{4(x+1)^2}\right) + \left(-\frac{1}{8x} + \frac{1}{4x-4} + \frac{1}{4x+}\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}z_1(x) &= p e^{\int \omega\, dx} \\ &= \mathrm{e}^{\int \left(-\frac{1}{8x} + \frac{1}{4x-4} + \frac{1}{4x+4}\right) dx} \\ &= \frac{(x-1)^{1/4}(x+1)^{1/4}}{x^{1/8}}\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-19x^3+7x}{-4x^4+4x^2}\, dx} \\ &= z_1 e^{-\frac{3\ln(x-1)}{4} - \frac{3\ln(x+1)}{4} - \frac{7\ln(x)}{8}} \\ &= z_1\left(\frac{1}{(x-1)^{3/4}(x+1)^{3/4}x^{7/8}}\right)\end{aligned}$$

Which simplifies to

$$y_1 = \frac{(x^2-1)^{1/4}}{(x-1)^{3/4}(x+1)^{3/4}x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}y_2 &= y_1 \int \frac{e^{\int -\frac{-19x^3+7x}{-4x^4+4x^2}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-\frac{3\ln(x-1)}{2} - \frac{3\ln(x+1)}{2} - \frac{7\ln(x)}{4}}}{(y_1)^2}\, dx \\ &= y_1\left(\int \frac{\mathrm{e}^{-\frac{3\ln(x-1)}{2} - \frac{3\ln(x+1)}{2} - \frac{7\ln(x)}{4}}(x-1)^{3/2}(x+1)^{3/2}x^2}{\sqrt{x^2-1}} dx\right)\end{aligned}$$

Therefore the solution is

$$y = c_1y_1 + c_2y_2$$

$$= c_1\left(\frac{(x^2-1)^{1/4}}{(x-1)^{3/4}(x+1)^{3/4}x}\right) + c_2\left(\frac{(x^2-1)^{1/4}}{(x-1)^{3/4}(x+1)^{3/4}x}\left(\int \frac{e^{-\frac{3\ln(x-1)}{2}-\frac{3\ln(x+1)}{2}-\frac{7\ln(x)}{4}}(x-1)^{3/2}(x+1)^{3/2}}{\sqrt{x^2-1}}\right.\right.$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$4x^2(-x^2+1)\left(\frac{d^2}{dx^2}y(x)\right) + x(-19x^2+7)\left(\frac{d}{dx}y(x)\right) - (14x^2+1)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$
- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{(14x^2+1)y(x)}{4(x^2-1)x^2} - \frac{(19x^2-7)\left(\frac{d}{dx}y(x)\right)}{4x(x^2-1)}$
- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

- ○ $(x+1)^2\cdot P_3(x)$ is analytic at $x=-1$

  $\left((x+1)^2\cdot P_3(x)\right)\Big|_{x=-1} = 0$
- ○ $x=-1$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = -1$

- Multiply by denominators

  $4(x^2-1)\,x^2\left(\frac{d^2}{dx^2}y(x)\right) + x(19x^2-7)\left(\frac{d}{dx}y(x)\right) + (14x^2+1)\,y(x) = 0$
- Change variables using $x = u-1$ so that the regular singular point is at $u=0$

  $(4u^4-16u^3+20u^2-8u)\left(\frac{d^2}{du^2}y(u)\right) + (19u^3-57u^2+50u-12)\left(\frac{d}{du}y(u)\right) + (14u^2-28u+15)\,y(\imath$
- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

□ Rewrite ODE with series expansions

- ○ Convert $u^m\cdot y(u)$ to series expansion for $m = 0..2$

  $u^m\cdot y(u) = \sum_{k=0}^{\infty} a_k u^{k+r+m}$
- ○ Shift index using $k->k-m$

  $u^m\cdot y(u) = \sum_{k=m}^{\infty} a_{k-m} u^{k+r}$
- ○ Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..3$

$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, u^{k+r-1+m}$

- Shift index using $k- >k+1-m$

$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$

- Convert $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m = 1..4$

$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, u^{k+r-2+m}$

- Shift index using $k- >k+2-m$

$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, u^{k+r}$

Rewrite ODE with series expansions

$-4a_0r(1+2r)\, u^{-1+r} + (-4a_1(1+r)\,(3+2r) + 5a_0(4r^2+6r+3))\, u^r + (-4a_2(2+r)\,(5+2r) +$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $-4r(1+2r) = 0$
- Values of r that satisfy the indicial equation
  $r \in \left\{0, -\frac{1}{2}\right\}$
- The coefficients of each power of u must be 0
  $[-4a_1(1+r)\,(3+2r) + 5a_0(4r^2+6r+3) = 0, -4a_2(2+r)\,(5+2r) + 5a_1(4r^2+14r+13) - a_0$
- Solve for the dependent coefficient(s)
  $\left\{a_1 = \frac{5a_0(4r^2+6r+3)}{4(2r^2+5r+3)}, a_2 = \frac{a_0(272r^4+1352r^3+2464r^2+1948r+639)}{16(4r^4+28r^3+71r^2+77r+30)}\right\}$
- Each term in the series must be 0, giving the recursion relation
  $4(5a_k + a_{k-2} - 4a_{k-1} - 2a_{k+1})\, k^2 + (8(5a_k + a_{k-2} - 4a_{k-1} - 2a_{k+1})\, r + 30a_k - a_{k-2} - 9a_{k-1} -$
- Shift index using $k- >k+2$
  $4(5a_{k+2} + a_k - 4a_{k+1} - 2a_{k+3})\,(k+2)^2 + (8(5a_{k+2} + a_k - 4a_{k+1} - 2a_{k+3})\, r + 30a_{k+2} - a_k - 9a_k$
- Recursion relation that defines series solution to ODE
  $a_{k+3} = \frac{4k^2a_k-16k^2a_{k+1}+20k^2a_{k+2}+8kra_k-32kra_{k+1}+40kra_{k+2}+4r^2a_k-16r^2a_{k+1}+20r^2a_{k+2}+15ka_k-73ka_{k+1}+110ka_{k+2}}{4(2k^2+4kr+2r^2+13k+13r+21)}$
- Recursion relation for $r = 0$
  $a_{k+3} = \frac{4k^2a_k-16k^2a_{k+1}+20k^2a_{k+2}+15ka_k-73ka_{k+1}+110ka_{k+2}+14a_k-85a_{k+1}+155a_{k+2}}{4(2k^2+13k+21)}$
- Solution for $r = 0$
  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+3} = \frac{4k^2a_k-16k^2a_{k+1}+20k^2a_{k+2}+15ka_k-73ka_{k+1}+110ka_{k+2}+14a_k-85a_{k+1}+155a_{k+2}}{4(2k^2+13k+21)}, a_1 = \frac{5c}{4}\right.$

2.1.103 Problem 105

Internal problem ID [9275]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 105
Date solved : Monday, January 27, 2025 at 06:00:52 PM
CAS classification : [[_2nd_order, _with_linear_symmetries]]

Solve

$$3x^2\left(-x^2+2\right)y''+x\left(-11x^2+1\right)y'+\left(-5x^2+1\right)y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.359 (sec)

Writing the ode as

$$\left(-3x^4+6x^2\right)y''+\left(-11x^3+x\right)y'+\left(-5x^2+1\right)y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= -3x^4+6x^2 \\ B &= -11x^3+x \\ C &= -5x^2+1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{-5x^4-4x^2-35}{36\left(x^3-2x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -5x^4-4x^2-35 \\ t &= 36\left(x^3-2x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{-5x^4-4x^2-35}{36\left(x^3-2x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.190: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 4 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 36(x^3 - 2x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = \sqrt{2}$ of order 2. There is a pole at $x = -\sqrt{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{7}{64\left(x-\sqrt{2}\right)^2} - \frac{7}{64\left(x+\sqrt{2}\right)^2} + \frac{31\sqrt{2}}{384\left(x-\sqrt{2}\right)} - \frac{31\sqrt{2}}{384\left(x+\sqrt{2}\right)} - \frac{35}{144x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{35}{144}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{12} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{5}{12} \end{aligned}$$

For the pole at $x=\sqrt{2}$ let b be the coefficient of $\frac{1}{\left(x-\sqrt{2}\right)^{2}}$ in the partial fractions decomposition of r given above. Therefore $b=-\frac{7}{64}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^{+} &= \frac{1}{2}+\sqrt{1+4b} = \frac{7}{8} \\
\alpha_c^{-} &= \frac{1}{2}-\sqrt{1+4b} = \frac{1}{8}
\end{aligned}
$$

For the pole at $x=-\sqrt{2}$ let b be the coefficient of $\frac{1}{\left(x+\sqrt{2}\right)^{2}}$ in the partial fractions decomposition of r given above. Therefore $b=-\frac{7}{64}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^{+} &= \frac{1}{2}+\sqrt{1+4b} = \frac{7}{8} \\
\alpha_c^{-} &= \frac{1}{2}-\sqrt{1+4b} = \frac{1}{8}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = \frac{-5x^4-4x^2-35}{36\left(x^3-2x\right)^2}
$$

Since the $\gcd(s,t)=1$. This gives $b=-\frac{5}{36}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= \frac{1}{2}+\sqrt{1+4b} = \frac{5}{6} \\
\alpha_\infty^{-} &= \frac{1}{2}-\sqrt{1+4b} = \frac{1}{6}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{-5x^4-4x^2-35}{36\left(x^3-2x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{7}{12}$	$\frac{5}{12}$
$\sqrt{2}$	2	0	$\frac{7}{8}$	$\frac{1}{8}$
$-\sqrt{2}$	2	0	$\frac{7}{8}$	$\frac{1}{8}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{5}{6}$	$\frac{1}{6}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{+}=\frac{5}{6}$ then

$$
\begin{aligned}
d &= \alpha_\infty^{+} - \left(\alpha_{c_1}^{+} + \alpha_{c_2}^{-} + \alpha_{c_3}^{-}\right) \\
&= \frac{5}{6} - \left(\frac{5}{6}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2} \right) + \left((-)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^-}{x-c_3} \right) + (+)[\sqrt{r}]_\infty \\
&= \frac{7}{12x} + \frac{1}{8x-8\sqrt{2}} + \frac{1}{8x+8\sqrt{2}} + (0) \\
&= \frac{7}{12x} + \frac{1}{8x-8\sqrt{2}} + \frac{1}{8x+8\sqrt{2}} \\
&= \frac{5x^2-7}{6x^3-12x}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{7}{12x} + \frac{1}{8x-8\sqrt{2}} + \frac{1}{8x+8\sqrt{2}}\right)(0) + \left(\left(-\frac{7}{12x^2} - \frac{1}{8\left(x-\sqrt{2}\right)^2} - \frac{1}{8\left(x+\sqrt{2}\right)^2}\right) + \left(\frac{7}{12x} + \frac{1}{8x-}\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx} \\
&= e^{\int \left(\frac{7}{12x} + \frac{1}{8x-8\sqrt{2}} + \frac{1}{8x+8\sqrt{2}}\right) dx} \\
&= \left(x-\sqrt{2}\right)^{1/8} \left(x+\sqrt{2}\right)^{1/8} x^{7/12}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{-11x^3+x}{-3x^4+6x^2}\, dx} \\
&= z_1 e^{-\frac{7\ln\left(x^2-2\right)}{8} - \frac{\ln(x)}{12}} \\
&= z_1 \left(\frac{1}{\left(x^2-2\right)^{7/8} x^{1/12}} \right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{\sqrt{x}}{\left(x^2-2\right)^{3/4}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-11x^3+x}{-3x^4+6x^2} \, dx}}{(y_1)^2} \, dx \\
&= y_1 \int \frac{e^{-\frac{7\ln(x^2-2)}{4} - \frac{\ln(x)}{6}}}{(y_1)^2} \, dx \\
&= y_1 \left(\int \frac{e^{-\frac{7\ln(x^2-2)}{4} - \frac{\ln(x)}{6}} (x^2-2)^{3/2}}{x} dx \right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{\sqrt{x}}{(x^2-2)^{3/4}} \right) + c_2 \left(\frac{\sqrt{x}}{(x^2-2)^{3/4}} \left(\int \frac{e^{-\frac{7\ln(x^2-2)}{4} - \frac{\ln(x)}{6}} (x^2-2)^{3/2}}{x} dx \right) \right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$3x^2(-x^2+2)\left(\frac{d^2}{dx^2}y(x)\right) + x(-11x^2+1)\left(\frac{d}{dx}y(x)\right) + (-5x^2+1)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{(5x^2-1)y(x)}{3x^2(x^2-2)} - \frac{(11x^2-1)\left(\frac{d}{dx}y(x)\right)}{3x(x^2-2)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x) + \frac{(11x^2-1)\left(\frac{d}{dx}y(x)\right)}{3x(x^2-2)} + \frac{(5x^2-1)y(x)}{3x^2(x^2-2)} = 0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

  $\left[P_2(x) = \frac{11x^2-1}{3x(x^2-2)}, P_3(x) = \frac{5x^2-1}{3x^2(x^2-2)}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

  $(x \cdot P_2(x))\Big|_{x=0} = \frac{1}{6}$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $(x^2 \cdot P_3(x))\Big|_{x=0} = \frac{1}{6}$

  ◦ $x = 0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $3x^2(x^2-2)\left(\frac{d^2}{dx^2}y(x)\right) + x(11x^2-1)\left(\frac{d}{dx}y(x)\right) + (5x^2-1)\,y(x) = 0$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

- Convert $x^m \cdot y(x)$ to series expansion for $m = 0..2$

  $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$
- Shift index using $k- > k - m$

  $x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$
- Convert $x^m \cdot \left(\frac{d}{dx} y(x)\right)$ to series expansion for $m = 1..3$

  $x^m \cdot \left(\frac{d}{dx} y(x)\right) = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r-1+m}$
- Shift index using $k- > k + 1 - m$

  $x^m \cdot \left(\frac{d}{dx} y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m} (k+1-m+r)\, x^{k+r}$
- Convert $x^m \cdot \left(\frac{d^2}{dx^2} y(x)\right)$ to series expansion for $m = 2..4$

  $x^m \cdot \left(\frac{d^2}{dx^2} y(x)\right) = \sum_{k=0}^{\infty} a_k (k+r)(k+r-1)\, x^{k+r-2+m}$
- Shift index using $k- > k + 2 - m$

  $x^m \cdot \left(\frac{d^2}{dx^2} y(x)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m} (k+2-m+r)(k+1-m+r)\, x^{k+r}$

  Rewrite ODE with series expansions

  $-a_0(-1+3r)(-1+2r)\, x^r - a_1(2+3r)(1+2r)\, x^{1+r} + \left(\sum_{k=2}^{\infty} (-a_k(3k+3r-1)(2k+2r-1) + a_k$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $-(-1+3r)(-1+2r) = 0$
- Values of r that satisfy the indicial equation

  $r \in \left\{\frac{1}{2}, \frac{1}{3}\right\}$
- Each term must be 0

  $-a_1(2+3r)(1+2r) = 0$
- Solve for the dependent coefficient(s)

  $a_1 = 0$
- Each term in the series must be 0, giving the recursion relation

  $-6\left(\frac{(-k-r+1)a_{k-2}}{2} + \left(k+r-\frac{1}{2}\right) a_k\right)\left(k-\frac{1}{3}+r\right) = 0$
- Shift index using $k- > k + 2$

  $-6\left(\frac{(-k-1-r)a_k}{2} + \left(k+\frac{3}{2}+r\right) a_{k+2}\right)\left(k+\frac{5}{3}+r\right) = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+2} = \frac{(k+r+1)a_k}{2k+3+2r}$
- Recursion relation for $r = \frac{1}{2}$

  $a_{k+2} = \frac{\left(k+\frac{3}{2}\right)a_k}{2k+4}$
- Solution for $r = \frac{1}{2}$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}, a_{k+2} = \frac{\left(k+\frac{3}{2}\right)a_k}{2k+4}, a_1 = 0\right]$
- Recursion relation for $r = \frac{1}{3}$

  $a_{k+2} = \frac{\left(k+\frac{4}{3}\right)a_k}{2k+\frac{11}{3}}$
- Solution for $r = \frac{1}{3}$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{3}}, a_{k+2} = \frac{\left(k+\frac{4}{3}\right)a_k}{2k+\frac{11}{3}}, a_1 = 0\right]$
- Combine solutions and rename parameters

$$\left[y(x)=\left(\sum_{k=0}^{\infty}a_k x^{k+\frac{1}{2}}\right)+\left(\sum_{k=0}^{\infty}b_k x^{k+\frac{1}{3}}\right), a_{k+2}=\frac{\left(k+\frac{3}{2}\right)a_k}{2k+4}, a_1=0, b_{k+2}=\frac{\left(k+\frac{4}{3}\right)b_k}{2k+\frac{11}{3}}, b_1=0\right]$$

2.1.104 Problem 106

Internal problem ID [9276]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 106
Date solved : `Monday, January 27, 2025 at 06:00:53 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$2x^2\left(x^2+2\right)y''-x\left(-7x^2+12\right)y'+\left(3x^2+7\right)y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.340 (sec)

Writing the ode as

$$\left(2x^4+4x^2\right)y''+\left(7x^3-12x\right)y'+\left(3x^2+7\right)y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2x^4+4x^2 \\ B &= 7x^3-12x \\ C &= 3x^2+7 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r=\frac{-3x^4-72x^2+128}{16\left(x^3+2x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -3x^4-72x^2+128 \\ t &= 16\left(x^3+2x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{-3x^4-72x^2+128}{16\left(x^3+2x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.192: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 6 - 4 \\
&= 2
\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16(x^3 + 2x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = i\sqrt{2}$ of order 2. There is a pole at $x = -i\sqrt{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{2}{x^2} + \frac{65}{64\left(x - i\sqrt{2}\right)^2} + \frac{65}{64\left(x + i\sqrt{2}\right)^2} + \frac{135i\sqrt{2}}{128\left(x - i\sqrt{2}\right)} - \frac{135i\sqrt{2}}{128\left(x + i\sqrt{2}\right)}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = 2 \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -1
\end{aligned}$$

For the pole at $x = i\sqrt{2}$ let b be the coefficient of $\frac{1}{\left(x-i\sqrt{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{65}{64}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{13}{8}\\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{5}{8}\end{aligned}$$

For the pole at $x = -i\sqrt{2}$ let b be the coefficient of $\frac{1}{\left(x+i\sqrt{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{65}{64}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{13}{8}\\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{5}{8}\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{-3x^4 - 72x^2 + 128}{16\left(x^3 + 2x\right)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{3}{16}$. Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= 0\\ \alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{4}\\ \alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{4}\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{-3x^4 - 72x^2 + 128}{16\left(x^3 + 2x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	2	-1
$i\sqrt{2}$	2	0	$\frac{13}{8}$	$-\frac{5}{8}$
$-i\sqrt{2}$	2	0	$\frac{13}{8}$	$-\frac{5}{8}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{3}{4}$	$\frac{1}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{3}{4}$ then

$$\begin{aligned}d &= \alpha_\infty^+ - \left(\alpha_{c_1}^+ + \alpha_{c_2}^- + \alpha_{c_3}^-\right)\\ &= \frac{3}{4} - \left(\frac{3}{4}\right)\\ &= 0\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2} \right) + \left((-)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^-}{x-c_3} \right) + (+)[\sqrt{r}]_\infty \\ &= \frac{2}{x} - \frac{5}{8\left(x-i\sqrt{2}\right)} - \frac{5}{8\left(x+i\sqrt{2}\right)} + (0) \\ &= \frac{2}{x} - \frac{5}{8\left(x-i\sqrt{2}\right)} - \frac{5}{8\left(x+i\sqrt{2}\right)} \\ &= \frac{2}{x} - \frac{5x}{4x^2+8}\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{2}{x} - \frac{5}{8\left(x-i\sqrt{2}\right)} - \frac{5}{8\left(x+i\sqrt{2}\right)}\right)(0) + \left(\left(-\frac{2}{x^2} + \frac{5}{8\left(x-i\sqrt{2}\right)^2} + \frac{5}{8\left(x+i\sqrt{2}\right)^2}\right) + \left(\frac{2}{x} - \frac{}{8\left(x-\right.}\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}z_1(x) &= pe^{\int \omega\, dx} \\ &= e^{\int \left(\frac{2}{x} - \frac{5}{8\left(x-i\sqrt{2}\right)} - \frac{5}{8\left(x+i\sqrt{2}\right)}\right) dx} \\ &= \frac{x^2}{\left(x^2+2\right)^{5/8}}\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{7x^3-12x}{2x^4+4x^2}\, dx} \\ &= z_1 e^{-\frac{13\ln\left(x^2+2\right)}{8} + \frac{3\ln(x)}{2}} \\ &= z_1 \left(\frac{x^{3/2}}{\left(x^2+2\right)^{13/8}}\right)\end{aligned}$$

Which simplifies to

$$y_1 = \frac{x^{7/2}}{\left(x^2+2\right)^{9/4}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{7x^3-12x}{2x^4+4x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{13\ln(x^2+2)}{4}+3\ln(x)}}{(y_1)^2}\,dx \\
&= y_1 \left(\int \frac{e^{-\frac{13\ln(x^2+2)}{4}+3\ln(x)}(x^2+2)^{9/2}}{x^7}\,dx\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{x^{7/2}}{(x^2+2)^{9/4}}\right) + c_2\left(\frac{x^{7/2}}{(x^2+2)^{9/4}}\left(\int \frac{e^{-\frac{13\ln(x^2+2)}{4}+3\ln(x)}(x^2+2)^{9/2}}{x^7}\,dx\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$2x^2(x^2+2)\left(\frac{d^2}{dx^2}y(x)\right) - x(-7x^2+12)\left(\frac{d}{dx}y(x)\right) + (3x^2+7)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{(3x^2+7)y(x)}{2(x^2+2)x^2} - \frac{(7x^2-12)\left(\frac{d}{dx}y(x)\right)}{2x(x^2+2)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x) + \frac{(7x^2-12)\left(\frac{d}{dx}y(x)\right)}{2x(x^2+2)} + \frac{(3x^2+7)y(x)}{2(x^2+2)x^2} = 0$

- ☐ Check to see if x_0 is a regular singular point
  - ◦ Define functions

    $\left[P_2(x) = \frac{7x^2-12}{2x(x^2+2)}, P_3(x) = \frac{3x^2+7}{2(x^2+2)x^2}\right]$
  - ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left.(x \cdot P_2(x))\right|_{x=0} = -3$
  - ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $\left.(x^2 \cdot P_3(x))\right|_{x=0} = \frac{7}{4}$
  - ◦ $x = 0$is a regular singular point

    Check to see if x_0 is a regular singular point

    $x_0 = 0$

- Multiply by denominators

  $2x^2(x^2+2)\left(\frac{d^2}{dx^2}y(x)\right) + x(7x^2-12)\left(\frac{d}{dx}y(x)\right) + (3x^2+7)\,y(x) = 0$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

- ☐ Rewrite ODE with series expansions
  - Convert $x^m \cdot y(x)$ to series expansion for $m = 0..2$

    $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$
  - Shift index using $k- > k - m$

    $x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$
  - Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m = 1..3$

    $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1+m}$
  - Shift index using $k- > k + 1 - m$

    $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$
  - Convert $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m = 2..4$

    $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-2+m}$
  - Shift index using $k- > k + 2 - m$

    $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(-1+2r)\,(-7+2r)\, x^r + a_1(1+2r)\,(-5+2r)\, x^{1+r} + \left(\sum_{k=2}^{\infty} (a_k(2k+2r-1)\,(2k+2r-7) + a_{k-}\right.$
- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-1+2r)\,(-7+2r) = 0$
- Values of r that satisfy the indicial equation

  $r \in \left\{\frac{1}{2}, \frac{7}{2}\right\}$
- Each term must be 0

  $a_1(1+2r)\,(-5+2r) = 0$
- Solve for the dependent coefficient(s)

  $a_1 = 0$
- Each term in the series must be 0, giving the recursion relation

  $4\left(k+r-\frac{1}{2}\right)\left(\frac{a_{k-2}(k+r-1)}{2} + a_k\left(k+r-\frac{7}{2}\right)\right) = 0$
- Shift index using $k- > k + 2$

  $4\left(k+\frac{3}{2}+r\right)\left(\frac{a_k(k+r+1)}{2} + a_{k+2}\left(k-\frac{3}{2}+r\right)\right) = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{a_k(k+r+1)}{2k-3+2r}$
- Recursion relation for $r = \frac{1}{2}$

  $a_{k+2} = -\frac{a_k\left(k+\frac{3}{2}\right)}{2k-2}$
- Solution for $r = \frac{1}{2}$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}, a_{k+2} = -\frac{a_k\left(k+\frac{3}{2}\right)}{2k-2}, a_1 = 0\right]$
- Recursion relation for $r = \frac{7}{2}$

  $a_{k+2} = -\frac{a_k\left(k+\frac{9}{2}\right)}{2k+4}$
- Solution for $r = \frac{7}{2}$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+\frac{7}{2}}, a_{k+2} = -\frac{a_k\left(k+\frac{9}{2}\right)}{2k+4}, a_1 = 0\right]$

- Combine solutions and rename parameters

$$\left[y(x)=\left(\sum_{k=0}^{\infty}a_k x^{k+\frac{1}{2}}\right)+\left(\sum_{k=0}^{\infty}b_k x^{k+\frac{7}{2}}\right), a_{k+2}=-\frac{a_k\left(k+\frac{3}{2}\right)}{2k-2}, a_1=0, b_{k+2}=-\frac{b_k\left(k+\frac{9}{2}\right)}{2k+4}, b_1=0\right]$$

2.1.105 Problem 107

Internal problem ID [9277]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 107
Date solved : `Monday, January 27, 2025 at 06:00:54 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$2x^2\left(x^2+2\right)y''+x\left(7x^2+4\right)y'-\left(-3x^2+1\right)y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.312 (sec)

Writing the ode as

$$\left(2x^4+4x^2\right)y''+\left(7x^3+4x\right)y'+\left(3x^2-1\right)y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2x^4+4x^2 \\ B &= 7x^3+4x \\ C &= 3x^2-1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r=\frac{-3x^2+24}{16\left(x^2+2\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -3x^2+24 \\ t &= 16\left(x^2+2\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{-3x^2+24}{16\left(x^2+2\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.194: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16(x^2+2)^2$. There is a pole at $x = i\sqrt{2}$ of order 2. There is a pole at $x = -i\sqrt{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{15}{64\left(x - i\sqrt{2}\right)^2} - \frac{15}{64\left(x + i\sqrt{2}\right)^2} - \frac{9i\sqrt{2}}{128\left(x - i\sqrt{2}\right)} + \frac{9i\sqrt{2}}{128\left(x + i\sqrt{2}\right)}$$

For the pole at $x = i\sqrt{2}$ let b be the coefficient of $\frac{1}{\left(x - i\sqrt{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{15}{64}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{8} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{3}{8} \end{aligned}$$

For the pole at $x = -i\sqrt{2}$ let b be the coefficient of $\frac{1}{\left(x + i\sqrt{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{15}{64}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{8} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{3}{8} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{-3x^2 + 24}{16\left(x^2 + 2\right)^2}$$

Since the gcd$(s,t) = 1$. This gives $b = -\frac{3}{16}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{4} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{4}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{-3x^2 + 24}{16\left(x^2 + 2\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
$i\sqrt{2}$	2	0	$\frac{5}{8}$	$\frac{3}{8}$
$-i\sqrt{2}$	2	0	$\frac{5}{8}$	$\frac{3}{8}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{3}{4}$	$\frac{1}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{3}{4}$ then

$$\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^- + \alpha_{c_2}^-\right) \\
&= \frac{3}{4} - \left(\frac{3}{4}\right) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2} \right) + (+)[\sqrt{r}]_\infty \\
&= \frac{3}{8\left(x - i\sqrt{2}\right)} + \frac{3}{8\left(x + i\sqrt{2}\right)} + (0) \\
&= \frac{3}{8\left(x - i\sqrt{2}\right)} + \frac{3}{8\left(x + i\sqrt{2}\right)} \\
&= \frac{3x}{4x^2 + 8}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{3}{8\left(x - i\sqrt{2}\right)} + \frac{3}{8\left(x + i\sqrt{2}\right)}\right)(0) + \left(\left(-\frac{3}{8\left(x - i\sqrt{2}\right)^2} - \frac{3}{8\left(x + i\sqrt{2}\right)^2}\right) + \left(\frac{3}{8\left(x - i\sqrt{2}\right)} + \frac{}{8(}\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega\, dx} \\ &= \mathrm{e}^{\int \left(\frac{3}{8\left(x-i\sqrt{2}\right)} + \frac{3}{8\left(x+i\sqrt{2}\right)}\right) dx} \\ &= \left(-x^2 - 2\right)^{3/8} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{7x^3+4x}{2x^4+4x^2}\, dx} \\ &= z_1 e^{-\frac{5\ln\left(x^2+2\right)}{8} - \frac{\ln(x)}{2}} \\ &= z_1\left(\frac{1}{\left(x^2+2\right)^{5/8}\sqrt{x}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{(-1)^{3/8}}{\left(x^2+2\right)^{1/4}\sqrt{x}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{7x^3+4x}{2x^4+4x^2}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-\frac{5\ln\left(x^2+2\right)}{4} - \ln(x)}}{(y_1)^2}\, dx \\ &= y_1\left(\int -\mathrm{e}^{-\frac{5\ln\left(x^2+2\right)}{4} - \ln(x)}\sqrt{x^2+2}\, x(-1)^{1/4}\, dx\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\frac{(-1)^{3/8}}{\left(x^2+2\right)^{1/4}\sqrt{x}}\right) + c_2\left(\frac{(-1)^{3/8}}{\left(x^2+2\right)^{1/4}\sqrt{x}}\left(\int -\mathrm{e}^{-\frac{5\ln\left(x^2+2\right)}{4} - \ln(x)}\sqrt{x^2+2}\, x(-1)^{1/4}\, dx\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$2x^2(x^2+2)\left(\frac{d^2}{dx^2}y(x)\right)+x(7x^2+4)\left(\frac{d}{dx}y(x)\right)-(-3x^2+1)\,y(x)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x)=-\frac{(3x^2-1)y(x)}{2(x^2+2)x^2}-\frac{(7x^2+4)\left(\frac{d}{dx}y(x)\right)}{2x(x^2+2)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x)+\frac{(7x^2+4)\left(\frac{d}{dx}y(x)\right)}{2x(x^2+2)}+\frac{(3x^2-1)y(x)}{2(x^2+2)x^2}=0$

☐ Check to see if x_0 is a regular singular point

  - Define functions

    $\left[P_2(x)=\frac{7x^2+4}{2x(x^2+2)},P_3(x)=\frac{3x^2-1}{2(x^2+2)x^2}\right]$

  - $x\cdot P_2(x)$ is analytic at $x=0$

    $\left.(x\cdot P_2(x))\right|_{x=0}=1$

  - $x^2\cdot P_3(x)$ is analytic at $x=0$

    $\left.(x^2\cdot P_3(x))\right|_{x=0}=-\frac{1}{4}$

  - $x=0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=0$

- Multiply by denominators

  $2x^2(x^2+2)\left(\frac{d^2}{dx^2}y(x)\right)+x(7x^2+4)\left(\frac{d}{dx}y(x)\right)+(3x^2-1)\,y(x)=0$

- Assume series solution for $y(x)$

  $y(x)=\sum_{k=0}^{\infty}a_kx^{k+r}$

☐ Rewrite ODE with series expansions

  - Convert $x^m\cdot y(x)$ to series expansion for $m=0..2$

    $x^m\cdot y(x)=\sum_{k=0}^{\infty}a_kx^{k+r+m}$

  - Shift index using $k->k-m$

    $x^m\cdot y(x)=\sum_{k=m}^{\infty}a_{k-m}x^{k+r}$

  - Convert $x^m\cdot\left(\frac{d}{dx}y(x)\right)$ to series expansion for $m=1..3$

    $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,x^{k+r-1+m}$

  - Shift index using $k->k+1-m$

    $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,x^{k+r}$

  - Convert $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m=2..4$

    $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,x^{k+r-2+m}$

  - Shift index using $k->k+2-m$

    $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=-2+m}^{\infty}a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$

  Rewrite ODE with series expansions

$$a_0(1+2r)(-1+2r)x^r + a_1(3+2r)(1+2r)x^{1+r} + \left(\sum_{k=2}^{\infty} (a_k(2k+2r+1)(2k+2r-1) + a_{k-2}\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $(1+2r)(-1+2r) = 0$
- Values of r that satisfy the indicial equation
  $r \in \left\{-\frac{1}{2}, \frac{1}{2}\right\}$
- Each term must be 0
  $a_1(3+2r)(1+2r) = 0$
- Solve for the dependent coefficient(s)
  $a_1 = 0$
- Each term in the series must be 0, giving the recursion relation
  $4\left(\frac{a_{k-2}(k+r-1)}{2} + a_k\left(k+r+\frac{1}{2}\right)\right)\left(k+r-\frac{1}{2}\right) = 0$
- Shift index using $k->k+2$
  $4\left(\frac{a_k(k+r+1)}{2} + a_{k+2}\left(k+\frac{5}{2}+r\right)\right)\left(k+\frac{3}{2}+r\right) = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+2} = -\frac{a_k(k+r+1)}{2k+5+2r}$
- Recursion relation for $r = -\frac{1}{2}$
  $a_{k+2} = -\frac{a_k\left(k+\frac{1}{2}\right)}{2k+4}$
- Solution for $r = -\frac{1}{2}$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k-\frac{1}{2}}, a_{k+2} = -\frac{a_k\left(k+\frac{1}{2}\right)}{2k+4}, a_1 = 0\right]$
- Recursion relation for $r = \frac{1}{2}$
  $a_{k+2} = -\frac{a_k\left(k+\frac{3}{2}\right)}{2k+6}$
- Solution for $r = \frac{1}{2}$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}, a_{k+2} = -\frac{a_k\left(k+\frac{3}{2}\right)}{2k+6}, a_1 = 0\right]$
- Combine solutions and rename parameters
  $\left[y(x) = \left(\sum_{k=0}^{\infty} a_k x^{k-\frac{1}{2}}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{2}}\right), a_{k+2} = -\frac{a_k\left(k+\frac{1}{2}\right)}{2k+4}, a_1 = 0, b_{k+2} = -\frac{b_k\left(k+\frac{3}{2}\right)}{2k+6}, b_1 = 0\right]$

2.1.106 Problem 108

Internal problem ID [9278]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 108
Date solved : `Monday, January 27, 2025 at 06:00:55 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$2x^2\left(2x^2+1\right)y''+5x\left(6x^2+1\right)y'-\left(-40x^2+2\right)y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.517 (sec)

Writing the ode as

$$\left(4x^4+2x^2\right)y''+\left(30x^3+5x\right)y'+\left(40x^2-2\right)y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4x^4+2x^2 \\ B &= 30x^3+5x \\ C &= 40x^2-2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{20x^4+12x^2+21}{16\left(2x^3+x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 20x^4+12x^2+21 \\ t &= 16\left(2x^3+x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{20x^4+12x^2+21}{16\left(2x^3+x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.196: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 4 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16(2x^3 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = \frac{i\sqrt{2}}{2}$ of order 2. There is a pole at $x = -\frac{i\sqrt{2}}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{21}{16x^2} + \frac{5}{16\left(x - \frac{i\sqrt{2}}{2}\right)^2} + \frac{5}{16\left(x + \frac{i\sqrt{2}}{2}\right)^2} + \frac{13i\sqrt{2}}{16\left(x - \frac{i\sqrt{2}}{2}\right)} - \frac{13i\sqrt{2}}{16\left(x + \frac{i\sqrt{2}}{2}\right)}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{21}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{7}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{3}{4} \end{aligned}$$

For the pole at $x = \frac{i\sqrt{2}}{2}$ let b be the coefficient of $\frac{1}{\left(x-\frac{i\sqrt{2}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{5}{16}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{4}\\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{4}\end{aligned}$$

For the pole at $x = -\frac{i\sqrt{2}}{2}$ let b be the coefficient of $\frac{1}{\left(x+\frac{i\sqrt{2}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{5}{16}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{4}\\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{4}\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{20x^4 + 12x^2 + 21}{16\,(2x^3 + x)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{5}{16}$. Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= 0\\ \alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{4}\\ \alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{4}\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{20x^4 + 12x^2 + 21}{16\,(2x^3 + x)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{7}{4}$	$-\frac{3}{4}$
$\frac{i\sqrt{2}}{2}$	2	0	$\frac{5}{4}$	$-\frac{1}{4}$
$-\frac{i\sqrt{2}}{2}$	2	0	$\frac{5}{4}$	$-\frac{1}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{5}{4}$	$-\frac{1}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{5}{4}$ then

$$\begin{aligned}d &= \alpha_\infty^+ - \left(\alpha_{c_1}^+ + \alpha_{c_2}^- + \alpha_{c_3}^-\right)\\ &= \frac{5}{4} - \left(\frac{5}{4}\right)\\ &= 0\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x-c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{-}}{x-c_2} \right) + \left((-)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^{-}}{x-c_3} \right) + (+)[\sqrt{r}]_\infty \\
&= \frac{7}{4x} - \frac{1}{4\left(x-\frac{i\sqrt{2}}{2}\right)} - \frac{1}{4\left(x+\frac{i\sqrt{2}}{2}\right)} + (0) \\
&= \frac{7}{4x} - \frac{1}{4\left(x-\frac{i\sqrt{2}}{2}\right)} - \frac{1}{4\left(x+\frac{i\sqrt{2}}{2}\right)} \\
&= \frac{10x^2+7}{8x^3+4x}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{7}{4x} - \frac{1}{4\left(x-\frac{i\sqrt{2}}{2}\right)} - \frac{1}{4\left(x+\frac{i\sqrt{2}}{2}\right)} \right)(0) + \left(\left(-\frac{7}{4x^2} + \frac{1}{4\left(x-\frac{i\sqrt{2}}{2}\right)^2} + \frac{1}{4\left(x+\frac{i\sqrt{2}}{2}\right)^2} \right) + \left(\frac{7}{4x} - \frac{}{4} \right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(\frac{7}{4x} - \frac{1}{4\left(x-\frac{i\sqrt{2}}{2}\right)} - \frac{1}{4\left(x+\frac{i\sqrt{2}}{2}\right)} \right) dx} \\
&= \frac{2^{3/4} x^{7/4}}{2\left(2x^2+1\right)^{1/4}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{30x^3+5x}{4x^4+2x^2} \, dx} \\
&= z_1 e^{-\frac{5\ln\left(x\left(2x^2+1\right)\right)}{4}} \\
&= z_1 \left(\frac{1}{\left(2x^3+x\right)^{5/4}} \right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{2^{3/4} x^{3/4}}{2\left(2x^2+1\right)^{5/4} \left(2x^3+x\right)^{1/4}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{30x^3+5x}{4x^4+2x^2}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-\frac{5\ln(2x^3+x)}{2}}}{(y_1)^2}\, dx \\ &= y_1 \left(\int \frac{(2x^2+1)^{5/2}\sqrt{2}}{(2x^3+x)^2\, x^{3/2}} dx\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\frac{2^{3/4}x^{3/4}}{2(2x^2+1)^{5/4}(2x^3+x)^{1/4}}\right) + c_2 \left(\frac{2^{3/4}x^{3/4}}{2(2x^2+1)^{5/4}(2x^3+x)^{1/4}} \left(\int \frac{(2x^2+1)^{5/2}\sqrt{2}}{(2x^3+x)^2\, x^{3/2}} dx\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve
$2x^2(2x^2+1)\left(\frac{d^2}{dx^2}y(x)\right) + 5x(6x^2+1)\left(\frac{d}{dx}y(x)\right) - (-40x^2+2)\, y(x) = 0$

- Highest derivative means the order of the ODE is 2
  $\frac{d^2}{dx^2}y(x)$
- Isolate 2nd derivative
  $\frac{d^2}{dx^2}y(x) = -\frac{(20x^2-1)y(x)}{x^2(2x^2+1)} - \frac{5(6x^2+1)\left(\frac{d}{dx}y(x)\right)}{2x(2x^2+1)}$
- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin
  $\frac{d^2}{dx^2}y(x) + \frac{5(6x^2+1)\left(\frac{d}{dx}y(x)\right)}{2x(2x^2+1)} + \frac{(20x^2-1)y(x)}{x^2(2x^2+1)} = 0$

□ Check to see if x_0 is a regular singular point
  - Define functions
    $\left[P_2(x) = \frac{5(6x^2+1)}{2x(2x^2+1)}, P_3(x) = \frac{20x^2-1}{x^2(2x^2+1)}\right]$
  - $x \cdot P_2(x)$ is analytic at $x = 0$
    $\left.(x \cdot P_2(x))\right|_{x=0} = \frac{5}{2}$
  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$
    $\left.(x^2 \cdot P_3(x))\right|_{x=0} = -1$
  - $x = 0$is a regular singular point
    Check to see if x_0 is a regular singular point
    $x_0 = 0$
- Multiply by denominators
  $2x^2(2x^2+1)\left(\frac{d^2}{dx^2}y(x)\right) + 5x(6x^2+1)\left(\frac{d}{dx}y(x)\right) + (40x^2-2)\, y(x) = 0$
- Assume series solution for $y(x)$

$y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

- ☐ Rewrite ODE with series expansions
  - ∘ Convert $x^m \cdot y(x)$ to series expansion for $m = 0..2$

    $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$
  - ∘ Shift index using $k->k-m$

    $x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$
  - ∘ Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m = 1..3$

    $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1+m}$
  - ∘ Shift index using $k->k+1-m$

    $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$
  - ∘ Convert $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m = 2..4$

    $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, x^{k+r-2+m}$
  - ∘ Shift index using $k->k+2-m$

    $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(2+r)(-1+2r)\, x^r + a_1(3+r)(1+2r)\, x^{1+r} + \left(\sum_{k=2}^{\infty} (a_k(k+r+2)(2k+2r-1) + 2a_{k-2}(k+r\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(2+r)(-1+2r) = 0$
- Values of r that satisfy the indicial equation

  $r \in \left\{-2, \frac{1}{2}\right\}$
- Each term must be 0

  $a_1(3+r)(1+2r) = 0$
- Solve for the dependent coefficient(s)

  $a_1 = 0$
- Each term in the series must be 0, giving the recursion relation

  $2(k+r+2)\left(a_{k-2}(2k+1+2r) + \left(k+r-\frac{1}{2}\right) a_k\right) = 0$
- Shift index using $k->k+2$

  $2(k+r+4)\left(a_k(2k+2r+5) + \left(k+\frac{3}{2}+r\right) a_{k+2}\right) = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{2a_k(2k+2r+5)}{2k+3+2r}$
- Recursion relation for $r = -2$

  $a_{k+2} = -\frac{2a_k(2k+1)}{2k-1}$
- Solution for $r = -2$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k-2}, a_{k+2} = -\frac{2a_k(2k+1)}{2k-1}, a_1 = 0\right]$
- Recursion relation for $r = \frac{1}{2}$

  $a_{k+2} = -\frac{2a_k(2k+6)}{2k+4}$
- Solution for $r = \frac{1}{2}$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}, a_{k+2} = -\frac{2a_k(2k+6)}{2k+4}, a_1 = 0\right]$

- Combine solutions and rename parameters

$$\left[y(x)=\left(\sum_{k=0}^{\infty}a_k x^{k-2}\right)+\left(\sum_{k=0}^{\infty}b_k x^{k+\frac{1}{2}}\right), a_{k+2}=-\frac{2a_k(2k+1)}{2k-1}, a_1=0, b_{k+2}=-\frac{2b_k(2k+6)}{2k+4}, b_1=0\right]$$

Book : Collection of Kovacic problems
Section : section 1
Problem number : 109
Date solved : `Monday, January 27, 2025 at 06:00:56 PM`
CAS classification : `[[_2nd_order, _exact, _linear, _homogeneous]]`

Solve

$$x(x^2+1)\,y''+(7x^2+4)\,y'+8xy=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.331 (sec)

Writing the ode as

$$(x^3+x)\,y''+(7x^2+4)\,y'+8xy=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A &= x^3+x\\ B &= 7x^2+4\\ C &= 8x\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned}r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2}\end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{3x^4+14x^2+8}{4\,(x^3+x)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned}s &= 3x^4+14x^2+8\\ t &= 4(x^3+x)^2\end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{3x^4+14x^2+8}{4\,(x^3+x)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.198: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 4 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^3+x)^2$. There is a pole at $x=0$ of order 2. There is a pole at $x=i$ of order 2. There is a pole at $x=-i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{2}{x^2} - \frac{3}{16(x-i)^2} - \frac{3}{16(x+i)^2} + \frac{7i}{16(x-i)} - \frac{7i}{16(x+i)}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1 \end{aligned}$$

For the pole at $x = i$ let b be the coefficient of $\frac{1}{(x-i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{4} \end{aligned}$$

For the pole at $x = -i$ let b be the coefficient of $\frac{1}{(x+i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0\\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{4}\\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{4}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = \frac{3x^4 + 14x^2 + 8}{4\left(x^3 + x\right)^2}
$$

Since the $\gcd(s, t) = 1$. This gives $b = \frac{3}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0\\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2}\\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{3x^4 + 14x^2 + 8}{4\left(x^3 + x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	2	-1
i	2	0	$\frac{3}{4}$	$\frac{1}{4}$
$-i$	2	0	$\frac{3}{4}$	$\frac{1}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -\frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^- + \alpha_{c_3}^-\right)\\
&= -\frac{1}{2} - \left(-\frac{1}{2}\right)\\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{-}}{x-c_2}\right) + \left((-)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^{-}}{x-c_3}\right) + (-)[\sqrt{r}]_{\infty} \\
&= -\frac{1}{x} + \frac{1}{4x-4i} + \frac{1}{4x+4i} + (-)\,(0) \\
&= -\frac{1}{x} + \frac{1}{4x-4i} + \frac{1}{4x+4i} \\
&= -\frac{1}{x} + \frac{x}{2x^2+2}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(0) + 2\left(-\frac{1}{x} + \frac{1}{4x-4i} + \frac{1}{4x+4i}\right)(0) + \left(\left(\frac{1}{x^2} - \frac{1}{4\,(x-i)^2} - \frac{1}{4\,(x+i)^2}\right) + \left(-\frac{1}{x} + \frac{1}{4x-4i} + \frac{1}{4x+4i}\right)^2\right.
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= e^{\int \left(-\frac{1}{x} + \frac{1}{4x-4i} + \frac{1}{4x+4i}\right) dx} \\
&= \frac{\left(x^2+1\right)^{1/4}}{x}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{7x^2+4}{x^3+x}\, dx} \\
&= z_1 e^{-\frac{3\ln\left(x^2+1\right)}{4} - 2\ln(x)} \\
&= z_1 \left(\frac{1}{\left(x^2+1\right)^{3/4} x^2}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{1}{\sqrt{x^2+1}\, x^3}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{7x^2+4}{x^3+x}dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-\frac{3\ln(x^2+1)}{2}-4\ln(x)}}{(y_1)^2}\, dx \\
&= y_1 \left(\frac{x^5}{\sqrt{x^2+1}} - \frac{x^3}{3\sqrt{x^2+1}} + \frac{4x^7}{\sqrt{x^2+1}} + \frac{8x^9}{3\sqrt{x^2+1}} + \frac{x\sqrt{x^2+1}}{2} - \frac{\operatorname{arcsinh}(x)}{2} \right. \\
&\quad \left. + \frac{\sqrt{x^2+1}\, x^3}{3} - \frac{4x^5\sqrt{x^2+1}}{3} - \frac{8x^7\sqrt{x^2+1}}{3} \right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{1}{\sqrt{x^2+1}\, x^3} \right) + c_2 \left(\frac{1}{\sqrt{x^2+1}\, x^3} \left(\frac{x^5}{\sqrt{x^2+1}} - \frac{x^3}{3\sqrt{x^2+1}} + \frac{4x^7}{\sqrt{x^2+1}} + \frac{8x^9}{3\sqrt{x^2+1}} \right. \right. \\
&\quad \left. \left. + \frac{x\sqrt{x^2+1}}{2} - \frac{\operatorname{arcsinh}(x)}{2} + \frac{\sqrt{x^2+1}\, x^3}{3} - \frac{4x^5\sqrt{x^2+1}}{3} - \frac{8x^7\sqrt{x^2+1}}{3} \right) \right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x(x^2+1)\left(\frac{d^2}{dx^2}y(x)\right) + (7x^2+4)\left(\frac{d}{dx}y(x)\right) + 8xy(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$
- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{8y(x)}{x^2+1} - \frac{(7x^2+4)\left(\frac{d}{dx}y(x)\right)}{x(x^2+1)}$
- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x) + \frac{(7x^2+4)\left(\frac{d}{dx}y(x)\right)}{x(x^2+1)} + \frac{8y(x)}{x^2+1} = 0$

☐ Check to see if x_0 is a regular singular point

  - Define functions

    $\left[P_2(x) = \frac{7x^2+4}{x(x^2+1)}, P_3(x) = \frac{8}{x^2+1}\right]$
  - $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left.(x \cdot P_2(x))\right|_{x=0} = 4$
  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $\left.(x^2 \cdot P_3(x))\right|_{x=0} = 0$
  - $x = 0$is a regular singular point

    Check to see if x_0 is a regular singular point

    $x_0 = 0$

- Multiply by denominators

$$x(x^2+1)\left(\frac{d^2}{dx^2}y(x)\right)+(7x^2+4)\left(\frac{d}{dx}y(x)\right)+8xy(x)=0$$

- Assume series solution for $y(x)$

$$y(x)=\sum_{k=0}^{\infty} a_k x^{k+r}$$

□ Rewrite ODE with series expansions

- ∘ Convert $x\cdot y(x)$ to series expansion

$$x\cdot y(x)=\sum_{k=0}^{\infty} a_k x^{k+r+1}$$

- ∘ Shift index using $k->k-1$

$$x\cdot y(x)=\sum_{k=1}^{\infty} a_{k-1} x^{k+r}$$

- ∘ Convert $x^m\cdot\left(\frac{d}{dx}y(x)\right)$ to series expansion for $m=0..2$

$$x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$$

- ∘ Shift index using $k->k+1-m$

$$x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$$

- ∘ Convert $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m=1..3$

$$x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r-2+m}$$

- ∘ Shift index using $k->k+2-m$

$$x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$$

Rewrite ODE with series expansions

$$a_0r(3+r)\,x^{-1+r}+a_1(1+r)\,(4+r)\,x^r+\left(\sum_{k=1}^{\infty}\left(a_{k+1}(k+r+1)\,(k+r+4)+a_{k-1}(k+r+3)\,(k+\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $r(3+r)=0$
- Values of r that satisfy the indicial equation
  $r\in\{-3,0\}$
- Each term must be 0
  $a_1(1+r)\,(4+r)=0$
- Each term in the series must be 0, giving the recursion relation
  $(k+r+1)\,(a_{k+1}(k+r+4)+a_{k-1}(k+r+3))=0$
- Shift index using $k->k+1$
  $(k+r+2)\,(a_{k+2}(k+5+r)+a_k(k+r+4))=0$
- Recursion relation that defines series solution to ODE

2.1.108 Problem 110

Internal problem ID [9280]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 110
Date solved : `Monday, January 27, 2025 at 06:00:56 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$2x^2\left(x^2+1\right)y''+x\left(8x^2+3\right)y'-\left(-4x^2+3\right)y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.312 (sec)

Writing the ode as

$$\left(2x^4+2x^2\right)y''+\left(8x^3+3x\right)y'+\left(4x^2-3\right)y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A&=2x^4+2x^2\\ B&=8x^3+3x\\ C&=4x^2-3 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r&=\frac{s}{t}\\ &=\frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{36x^2+21}{16\left(x^3+x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s&=36x^2+21\\ t&=16\left(x^3+x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{36x^2+21}{16\left(x^3+x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.200: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 2 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16(x^3 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = i$ of order 2. There is a pole at $x = -i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{15}{64\,(x-i)^2} - \frac{15}{64\,(x+i)^2} + \frac{27i}{64\,(x-i)} - \frac{27i}{64\,(x+i)} + \frac{21}{16x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{21}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{4} \end{aligned}$$

For the pole at $x = i$ let b be the coefficient of $\frac{1}{(x-i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{15}{64}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{8} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{3}{8} \end{aligned}$$

For the pole at $x=-i$ let b be the coefficient of $\frac{1}{(x+i)^2}$ in the partial fractions decomposition of r given above. Therefore $b=-\frac{15}{64}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0\\
\alpha_c^+ &= \frac{1}{2}+\sqrt{1+4b}=\frac{5}{8}\\
\alpha_c^- &= \frac{1}{2}-\sqrt{1+4b}=\frac{3}{8}
\end{aligned}
$$

Since the order of r at ∞ is $4>2$ then

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0\\
\alpha_\infty^+ &= 0\\
\alpha_\infty^- &= 1
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r=\frac{36x^2+21}{16\left(x^3+x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{7}{4}$	$-\frac{3}{4}$
i	2	0	$\frac{5}{8}$	$\frac{3}{8}$
$-i$	2	0	$\frac{5}{8}$	$\frac{3}{8}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+=0$ then

$$
\begin{aligned}
d &= \alpha_\infty^+-\left(\alpha_{c_1}^-+\alpha_{c_2}^-+\alpha_{c_3}^-\right)\\
&= 0-(0)\\
&= 0
\end{aligned}
$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$
\omega=\sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c+\frac{\alpha_c^{s(c)}}{x-c}\right)+s(\infty)[\sqrt{r}]_\infty
$$

Substituting the above values in the above results in

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1}+\frac{\alpha_{c_1}^-}{x-c_1}\right)+\left((-)[\sqrt{r}]_{c_2}+\frac{\alpha_{c_2}^-}{x-c_2}\right)+\left((-)[\sqrt{r}]_{c_3}+\frac{\alpha_{c_3}^-}{x-c_3}\right)+(+)[\sqrt{r}]_\infty\\
&= -\frac{3}{4x}+\frac{3}{8\left(x-i\right)}+\frac{3}{8\left(x+i\right)}+(0)\\
&= -\frac{3}{4x}+\frac{3}{8\left(x-i\right)}+\frac{3}{8\left(x+i\right)}\\
&= -\frac{3}{4x\left(x^2+1\right)}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{3}{4x} + \frac{3}{8(x-i)} + \frac{3}{8(x+i)}\right)(0) + \left(\left(\frac{3}{4x^2} - \frac{3}{8(x-i)^2} - \frac{3}{8(x+i)^2}\right) + \left(-\frac{3}{4x} + \frac{3}{8(x-i)} + \frac{}{8}\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= e^{\int \left(-\frac{3}{4x} + \frac{3}{8(x-i)} + \frac{3}{8(x+i)}\right) dx} \\ &= \frac{(x^2+1)^{3/8}}{x^{3/4}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{8x^3+3x}{2x^4+2x^2}\, dx} \\ &= z_1 e^{-\frac{3\ln(x)}{4} - \frac{5\ln(x^2+1)}{8}} \\ &= z_1 \left(\frac{1}{x^{3/4}(x^2+1)^{5/8}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{1}{x^{3/2}(x^2+1)^{1/4}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{8x^3+3x}{2x^4+2x^2}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-\frac{3\ln(x)}{2} - \frac{5\ln(x^2+1)}{4}}}{(y_1)^2}\, dx \\ &= y_1 \left(\int e^{-\frac{3\ln(x)}{2} - \frac{5\ln(x^2+1)}{4}} x^3 \sqrt{x^2+1}\, dx\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\frac{1}{x^{3/2}(x^2+1)^{1/4}}\right) + c_2 \left(\frac{1}{x^{3/2}(x^2+1)^{1/4}} \left(\int e^{-\frac{3\ln(x)}{2} - \frac{5\ln(x^2+1)}{4}} x^3 \sqrt{x^2+1}\, dx\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$2x^2(x^2+1)\left(\frac{d^2}{dx^2}y(x)\right)+x(8x^2+3)\left(\frac{d}{dx}y(x)\right)-(-4x^2+3)\,y(x)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x)=-\frac{(4x^2-3)y(x)}{2x^2(x^2+1)}-\frac{(8x^2+3)\left(\frac{d}{dx}y(x)\right)}{2x(x^2+1)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d^2}{dx^2}y(x)+\frac{(8x^2+3)\left(\frac{d}{dx}y(x)\right)}{2x(x^2+1)}+\frac{(4x^2-3)y(x)}{2x^2(x^2+1)}=0$

- □ Check to see if x_0 is a regular singular point
  - ∘ Define functions

2.1.109 Problem 111

Internal problem ID [9281]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 111
Date solved : `Monday, January 27, 2025 at 06:00:57 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$9x^2y'' + 3x\left(x^2+3\right)y' - \left(-5x^2+1\right)y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.277 (sec)

Writing the ode as

$$9x^2y'' + \left(3x^3+9x\right)y' + \left(5x^2-1\right)y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 9x^2 \\ B &= 3x^3+9x \\ C &= 5x^2-1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^4-8x^2-5}{36x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^4-8x^2-5 \\ t &= 36x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^4-8x^2-5}{36x^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.202: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 4 \\ &= -2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 36x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{x^2}{36} - \frac{2}{9} - \frac{5}{36x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{5}{36}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{6} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{6} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x}{6} - \frac{2}{3x} - \frac{7}{4x^3} - \frac{7}{x^5} - \frac{595}{16x^7} - \frac{889}{4x^9} - \frac{45647}{32x^{11}} - \frac{76811}{8x^{13}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{6}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= \frac{x}{6}\end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{x^2}{36}$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned}r &= \frac{s}{t} \\ &= \frac{x^4 - 8x^2 - 5}{36x^2} \\ &= Q + \frac{R}{36x^2} \\ &= \left(\frac{x^2}{36} - \frac{2}{9}\right) + \left(-\frac{5}{36x^2}\right) \\ &= \frac{x^2}{36} - \frac{2}{9} - \frac{5}{36x^2}\end{aligned}$$

We see that the coefficient of the term x in the quotient is $-\frac{2}{9}$. Now b can be found.

$$\begin{aligned}b &= \left(-\frac{2}{9}\right) - (0) \\ &= -\frac{2}{9}\end{aligned}$$

Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= \frac{x}{6} \\ \alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{2}{9}}{\frac{1}{6}} - 1\right) &&= -\frac{7}{6} \\ \alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{2}{9}}{\frac{1}{6}} - 1\right) &&= \frac{1}{6}\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^4 - 8x^2 - 5}{36x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{5}{6}$	$\frac{1}{6}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-2	$\frac{x}{6}$	$-\frac{7}{6}$	$\frac{1}{6}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{6}$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\ &= \frac{1}{6} - \left(\frac{1}{6}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{1}{6x} + (-)\left(\frac{x}{6}\right) \\ &= \frac{1}{6x} - \frac{x}{6} \\ &= \frac{1}{6x} - \frac{x}{6} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(\frac{1}{6x} - \frac{x}{6}\right)(0) + \left(\left(-\frac{1}{6x^2} - \frac{1}{6}\right) + \left(\frac{1}{6x} - \frac{x}{6}\right)^2 - \left(\frac{x^4 - 8x^2 - 5}{36x^2}\right)\right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= e^{\int \left(\frac{1}{6x} - \frac{x}{6}\right) dx} \\ &= x^{1/6} e^{-\frac{x^2}{12}} \end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{3x^3+9x}{9x^2}\,dx} \\
&= z_1 e^{-\frac{x^2}{12}-\frac{\ln(x)}{2}} \\
&= z_1 \left(\frac{e^{-\frac{x^2}{12}}}{\sqrt{x}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{e^{-\frac{x^2}{6}}}{x^{1/3}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{3x^3+9x}{9x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{x^2}{6}-\ln(x)}}{(y_1)^2}\,dx \\
&= y_1 \left(\int e^{-\frac{x^2}{6}-\ln(x)} x^{2/3} e^{\frac{x^2}{3}}\,dx\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{e^{-\frac{x^2}{6}}}{x^{1/3}}\right) + c_2 \left(\frac{e^{-\frac{x^2}{6}}}{x^{1/3}}\left(\int e^{-\frac{x^2}{6}-\ln(x)} x^{2/3} e^{\frac{x^2}{3}}\,dx\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$9x^2\left(\frac{d^2}{dx^2}y(x)\right) + 3x(x^2+3)\left(\frac{d}{dx}y(x)\right) - (-5x^2+1)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{(5x^2-1)y(x)}{9x^2} - \frac{(x^2+3)\left(\frac{d}{dx}y(x)\right)}{3x}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lir

  $\frac{d^2}{dx^2}y(x) + \frac{(x^2+3)\left(\frac{d}{dx}y(x)\right)}{3x} + \frac{(5x^2-1)y(x)}{9x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

$\left[P_2(x) = \frac{x^2+3}{3x}, P_3(x) = \frac{5x^2-1}{9x^2}\right]$

- $x \cdot P_2(x)$ is analytic at $x = 0$

  $\left(x \cdot P_2(x)\right)\bigg|_{x=0} = 1$

- $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = -\frac{1}{9}$

- $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $9x^2\left(\frac{d^2}{dx^2}y(x)\right) + 3x(x^2+3)\left(\frac{d}{dx}y(x)\right) + (5x^2-1)\,y(x) = 0$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

- ☐ Rewrite ODE with series expansions
  - Convert $x^m \cdot y(x)$ to series expansion for $m = 0..2$

    $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

  - Shift index using $k- >k-m$

    $x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

  - Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m = 1..3$

    $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$

  - Shift index using $k- >k+1-m$

    $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$

  - Convert $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

    $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(1+3r)\,(-1+3r)\,x^r + a_1(4+3r)\,(2+3r)\,x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(3k+3r+1)\,(3k+3r-1) + a_{k-2}(3k\right.\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(1+3r)\,(-1+3r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \left\{-\frac{1}{3}, \frac{1}{3}\right\}$

- Each term must be 0

  $a_1(4+3r)\,(2+3r) = 0$

- Solve for the dependent coefficient(s)

  $a_1 = 0$

- Each term in the series must be 0, giving the recursion relation

  $(3k+3r-1)\,(3a_kk + 3a_kr + a_k + a_{k-2}) = 0$

- Shift index using $k- >k+2$

  $(3k+3r+5)\,(3a_{k+2}(k+2) + 3a_{k+2}r + a_{k+2} + a_k) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{a_k}{3k+7+3r}$

- Recursion relation for $r=-\frac{1}{3}$

  $a_{k+2}=-\frac{a_k}{3k+6}$
- Solution for $r=-\frac{1}{3}$

  $$\left[y(x)=\sum_{k=0}^{\infty} a_k x^{k-\frac{1}{3}}, a_{k+2}=-\frac{a_k}{3k+6}, a_1=0\right]$$
- Recursion relation for $r=\frac{1}{3}$

  $a_{k+2}=-\frac{a_k}{3k+8}$
- Solution for $r=\frac{1}{3}$

  $$\left[y(x)=\sum_{k=0}^{\infty} a_k x^{k+\frac{1}{3}}, a_{k+2}=-\frac{a_k}{3k+8}, a_1=0\right]$$
- Combine solutions and rename parameters

  $$\left[y(x)=\left(\sum_{k=0}^{\infty} a_k x^{k-\frac{1}{3}}\right)+\left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{3}}\right), a_{k+2}=-\frac{a_k}{3k+6}, a_1=0, b_{k+2}=-\frac{b_k}{3k+8}, b_1=0\right]$$

2.1.110 Problem 112

Internal problem ID [9282]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 112
Date solved : `Monday, January 27, 2025 at 06:00:58 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$6x^2y'' + x(6x^2+1)\,y' + (9x^2+1)\,y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.336 (sec)

Writing the ode as

$$6x^2y'' + (6x^3+x)\,y' + (9x^2+1)\,y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 6x^2 \\ B &= 6x^3 + x \\ C &= 9x^2 + 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{36x^4 - 132x^2 - 35}{144x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 36x^4 - 132x^2 - 35 \\ t &= 144x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{36x^4 - 132x^2 - 35}{144x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.204: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 4 \\ &= -2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 144x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{x^2}{4} - \frac{11}{12} - \frac{35}{144x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{35}{144}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{12} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{5}{12} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x}{2} - \frac{11}{12x} - \frac{13}{12x^3} - \frac{143}{72x^5} - \frac{130}{27x^7} - \frac{17017}{1296x^9} - \frac{597961}{15552x^{11}} - \frac{11016863}{93312x^{13}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= \frac{x}{2}\end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{x^2}{4}$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned}r &= \frac{s}{t} \\ &= \frac{36x^4 - 132x^2 - 35}{144x^2} \\ &= Q + \frac{R}{144x^2} \\ &= \left(\frac{x^2}{4} - \frac{11}{12}\right) + \left(-\frac{35}{144x^2}\right) \\ &= \frac{x^2}{4} - \frac{11}{12} - \frac{35}{144x^2}\end{aligned}$$

We see that the coefficient of the term x in the quotient is $-\frac{11}{12}$. Now b can be found.

$$\begin{aligned}b &= \left(-\frac{11}{12}\right) - (0) \\ &= -\frac{11}{12}\end{aligned}$$

Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= \frac{x}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-\frac{11}{12}}{\frac{1}{2}} - 1\right) &= -\frac{17}{12} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-\frac{11}{12}}{\frac{1}{2}} - 1\right) &= \frac{5}{12}\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{36x^4 - 132x^2 - 35}{144x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{7}{12}$	$\frac{5}{12}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-2	$\frac{x}{2}$	$-\frac{17}{12}$	$\frac{5}{12}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{5}{12}$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\ &= \frac{5}{12} - \left(\frac{5}{12}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{5}{12x} + (-)\left(\frac{x}{2}\right) \\ &= \frac{5}{12x} - \frac{x}{2} \\ &= \frac{5}{12x} - \frac{x}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(\frac{5}{12x} - \frac{x}{2}\right)(0) + \left(\left(-\frac{5}{12x^2} - \frac{1}{2}\right) + \left(\frac{5}{12x} - \frac{x}{2}\right)^2 - \left(\frac{36x^4 - 132x^2 - 35}{144x^2}\right)\right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= e^{\int \left(\frac{5}{12x} - \frac{x}{2}\right) dx} \\ &= x^{5/12} e^{-\frac{x^2}{4}} \end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{6x^3+x}{6x^2}\,dx} \\
&= z_1 e^{-\frac{x^2}{4}-\frac{\ln(x)}{12}} \\
&= z_1\left(\frac{\mathrm{e}^{-\frac{x^2}{4}}}{x^{1/12}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = x^{1/3}\mathrm{e}^{-\frac{x^2}{2}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{6x^3+x}{6x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{x^2}{2}-\frac{\ln(x)}{6}}}{(y_1)^2}\,dx \\
&= y_1\left(\int \frac{\mathrm{e}^{-\frac{x^2}{2}-\frac{\ln(x)}{6}}\,\mathrm{e}^{x^2}}{x^{2/3}}dx\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(x^{1/3}\mathrm{e}^{-\frac{x^2}{2}}\right) + c_2\left(x^{1/3}\mathrm{e}^{-\frac{x^2}{2}}\left(\int \frac{\mathrm{e}^{-\frac{x^2}{2}-\frac{\ln(x)}{6}}\,\mathrm{e}^{x^2}}{x^{2/3}}dx\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$6x^2\left(\frac{d^2}{dx^2}y(x)\right) + x(6x^2+1)\left(\frac{d}{dx}y(x)\right) + (9x^2+1)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{(9x^2+1)y(x)}{6x^2} - \frac{(6x^2+1)\left(\frac{d}{dx}y(x)\right)}{6x}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x) + \frac{(6x^2+1)\left(\frac{d}{dx}y(x)\right)}{6x} + \frac{(9x^2+1)y(x)}{6x^2} = 0$

- ☐ Check to see if $x_0 = 0$ is a regular singular point
  - Define functions

$\left[P_2(x) = \frac{6x^2+1}{6x}, P_3(x) = \frac{9x^2+1}{6x^2}\right]$

- $x \cdot P_2(x)$ is analytic at $x = 0$

  $(x \cdot P_2(x))\Big|_{x=0} = \frac{1}{6}$

- $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $(x^2 \cdot P_3(x))\Big|_{x=0} = \frac{1}{6}$

- $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $6x^2\left(\frac{d^2}{dx^2}y(x)\right) + x(6x^2+1)\left(\frac{d}{dx}y(x)\right) + (9x^2+1)\,y(x) = 0$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

- ☐ Rewrite ODE with series expansions

  - Convert $x^m \cdot y(x)$ to series expansion for $m = 0..2$

    $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

  - Shift index using $k- >k-m$

    $x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

  - Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m = 1..3$

    $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$

  - Shift index using $k- >k+1-m$

    $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$

  - Convert $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

    $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\,x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(-1+3r)(-1+2r)\,x^r + a_1(2+3r)(1+2r)\,x^{1+r} + \left(\sum_{k=2}^{\infty} (a_k(3k+3r-1)(2k+2r-1) + 3a_{k-2}\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-1+3r)(-1+2r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \left\{\frac{1}{2}, \frac{1}{3}\right\}$

- Each term must be 0

  $a_1(2+3r)(1+2r) = 0$

- Solve for the dependent coefficient(s)

  $a_1 = 0$

- Each term in the series must be 0, giving the recursion relation

  $6\left(\left(k - \frac{1}{3} + r\right)a_k + a_{k-2}\right)\left(k + r - \frac{1}{2}\right) = 0$

- Shift index using $k- >k+2$

  $6\left(\left(k + \frac{5}{3} + r\right)a_{k+2} + a_k\right)\left(k + \frac{3}{2} + r\right) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{3a_k}{3k+5+3r}$

- Recursion relation for $r = \frac{1}{2}$

  $a_{k+2} = -\frac{3a_k}{3k+\frac{13}{2}}$
- Solution for $r = \frac{1}{2}$

  $$\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}, a_{k+2} = -\frac{3a_k}{3k+\frac{13}{2}}, a_1 = 0\right]$$
- Recursion relation for $r = \frac{1}{3}$

  $a_{k+2} = -\frac{3a_k}{3k+6}$
- Solution for $r = \frac{1}{3}$

  $$\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{3}}, a_{k+2} = -\frac{3a_k}{3k+6}, a_1 = 0\right]$$
- Combine solutions and rename parameters

  $$\left[y(x) = \left(\sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{3}}\right), a_{k+2} = -\frac{3a_k}{3k+\frac{13}{2}}, a_1 = 0, b_{k+2} = -\frac{3b_k}{3k+6}, b_1 = 0\right]$$

2.1.111 Problem 113

Internal problem ID [9283]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 113
Date solved : `Monday, January 27, 2025 at 06:00:59 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$9x^2\left(x^2+1\right)y''+3x\left(13x^2+3\right)y'-\left(-25x^2+1\right)y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.329 (sec)

Writing the ode as

$$\left(9x^4+9x^2\right)y''+\left(39x^3+9x\right)y'+\left(25x^2-1\right)y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A&=9x^4+9x^2\\ B&=39x^3+9x \\ C&=25x^2-1\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r&=\frac{s}{t} \\ &=\frac{2AB'-2BA'+B^2-4AC}{4A^2}\end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r=\frac{-9x^4+6x^2-5}{36\left(x^3+x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s&=-9x^4+6x^2-5\\ t&=36\left(x^3+x\right)^2\end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{-9x^4+6x^2-5}{36\left(x^3+x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.206: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 4 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 36(x^3 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = i$ of order 2. There is a pole at $x = -i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{5}{36\,(x-i)^2} - \frac{5}{36\,(x+i)^2} - \frac{i}{12\,(x-i)} + \frac{i}{12x+12i} - \frac{5}{36x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{5}{36}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{6} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{6} \end{aligned}$$

For the pole at $x = i$ let b be the coefficient of $\frac{1}{(x-i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{5}{36}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{6} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{6} \end{aligned}$$

For the pole at $x = -i$ let b be the coefficient of $\frac{1}{(x+i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{5}{36}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{6} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{6}
\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{-9x^4 + 6x^2 - 5}{36\left(x^3 + x\right)^2}$$

Since the $\gcd(s, t) = 1$. This gives $b = -\frac{1}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{-9x^4 + 6x^2 - 5}{36\left(x^3 + x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{5}{6}$	$\frac{1}{6}$
i	2	0	$\frac{5}{6}$	$\frac{1}{6}$
$-i$	2	0	$\frac{5}{6}$	$\frac{1}{6}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^- + \alpha_{c_3}^-\right) \\
&= \frac{1}{2} - \left(\frac{1}{2}\right) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2}\right) + \left((-)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^-}{x-c_3}\right) + (-)[\sqrt{r}]_\infty \\
&= \frac{1}{6x} + \frac{1}{6x-6i} + \frac{1}{6x+6i} + (-)(0) \\
&= \frac{1}{6x} + \frac{1}{6x-6i} + \frac{1}{6x+6i} \\
&= \frac{1}{6x} + \frac{x}{3x^2+3}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{6x} + \frac{1}{6x-6i} + \frac{1}{6x+6i}\right)(0) + \left(\left(-\frac{1}{6x^2} - \frac{1}{6(x-i)^2} - \frac{1}{6(x+i)^2}\right) + \left(\frac{1}{6x} + \frac{1}{6x-6i} + \frac{1}{6x+6i}\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx} \\
&= \mathrm{e}^{\int \left(\frac{1}{6x} + \frac{1}{6x-6i} + \frac{1}{6x+6i}\right) dx} \\
&= (x^2+1)^{1/6} (-x)^{1/6}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{39x^3+9x}{9x^4+9x^2}\, dx} \\
&= z_1 e^{-\frac{\ln(x)}{2} - \frac{5\ln(x^2+1)}{6}} \\
&= z_1 \left(\frac{1}{\sqrt{x}\,(x^2+1)^{5/6}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{(-x)^{1/6}}{\sqrt{x}\,(x^2+1)^{2/3}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{39x^3+9x}{9x^4+9x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-\ln(x) - \frac{5\ln(x^2+1)}{3}}}{(y_1)^2}\, dx \\
&= y_1 \left(\int \frac{\mathrm{e}^{-\ln(x) - \frac{5\ln(x^2+1)}{3}}\, x(x^2+1)^{4/3}}{(-x)^{1/3}}\, dx\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{(-x)^{1/6}}{\sqrt{x}\,(x^2+1)^{2/3}} \right) + c_2 \left(\frac{(-x)^{1/6}}{\sqrt{x}\,(x^2+1)^{2/3}} \left(\int \frac{e^{-\ln(x) - \frac{5\ln(x^2+1)}{3}} x(x^2+1)^{4/3}}{(-x)^{1/3}} dx \right) \right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$9x^2(x^2+1)\left(\frac{d^2}{dx^2}y(x)\right) + 3x(13x^2+3)\left(\frac{d}{dx}y(x)\right) - (-25x^2+1)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2

$\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

$\frac{d^2}{dx^2}y(x) = -\frac{(25x^2-1)y(x)}{9x^2(x^2+1)} - \frac{(13x^2+3)\left(\frac{d}{dx}y(x)\right)}{3x(x^2+1)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

$\frac{d^2}{dx^2}y(x) + \frac{(13x^2+3)\left(\frac{d}{dx}y(x)\right)}{3x(x^2+1)} + \frac{(25x^2-1)y(x)}{9x^2(x^2+1)} = 0$

□ Check to see if x_0 is a regular singular point

- ○ Define functions

- ○ $x \cdot P_2(x)$ is analytic at $x = 0$

$\left.(x \cdot P_2(x))\right|_{x=0} = 1$

- ○ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

$\left.(x^2 \cdot P_3(x))\right|_{x=0} = -\frac{1}{9}$

- ○ $x = 0$is a regular singular point

Check to see if x_0 is a regular singular point

$x_0 = 0$

- Multiply by denominators

$9x^2(x^2+1)\left(\frac{d^2}{dx^2}y(x)\right) + 3x(13x^2+3)\left(\frac{d}{dx}y(x)\right) + (25x^2-1)\,y(x) = 0$

- Assume series solution for $y(x)$

$y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

- ○ Convert $x^m \cdot y(x)$ to series expansion for $m = 0..2$

$x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- ○ Shift index using $k- >k - m$

$x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- ○ Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m = 1..3$

$x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$

- ○ Shift index using $k- >k + 1 - m$

$$x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$$

- Convert $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m = 2..4$

$$x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-2+m}$$

- Shift index using $k->k+2-m$

$$x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0(1+3r)\,(-1+3r)\, x^r + a_1(4+3r)\,(2+3r)\, x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(3k+3r+1)\,(3k+3r-1) + a_{k-2}(3k\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $(1+3r)\,(-1+3r) = 0$
- Values of r that satisfy the indicial equation
  $r \in \left\{-\frac{1}{3}, \frac{1}{3}\right\}$
- Each term must be 0
  $a_1(4+3r)\,(2+3r) = 0$
- Solve for the dependent coefficient(s)
  $a_1 = 0$
- Each term in the series must be 0, giving the recursion relation
  $9\left(\left(k-\frac{1}{3}+r\right)a_{k-2} + \left(k+r+\frac{1}{3}\right)a_k\right)\left(k-\frac{1}{3}+r\right) = 0$
- Shift index using $k->k+2$
  $9\left(\left(k+\frac{5}{3}+r\right)a_k + \left(k+\frac{7}{3}+r\right)a_{k+2}\right)\left(k+\frac{5}{3}+r\right) = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+2} = -\frac{(3k+3r+5)a_k}{3k+7+3r}$
- Recursion relation for $r = -\frac{1}{3}$
  $a_{k+2} = -\frac{(3k+4)a_k}{3k+6}$
- Solution for $r = -\frac{1}{3}$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k-\frac{1}{3}}, a_{k+2} = -\frac{(3k+4)a_k}{3k+6}, a_1 = 0\right]$
- Recursion relation for $r = \frac{1}{3}$
  $a_{k+2} = -\frac{(3k+6)a_k}{3k+8}$
- Solution for $r = \frac{1}{3}$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{3}}, a_{k+2} = -\frac{(3k+6)a_k}{3k+8}, a_1 = 0\right]$
- Combine solutions and rename parameters
  $\left[y(x) = \left(\sum_{k=0}^{\infty} a_k x^{k-\frac{1}{3}}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{3}}\right), a_{k+2} = -\frac{(3k+4)a_k}{3k+6}, a_1 = 0, b_{k+2} = -\frac{(3k+6)b_k}{3k+8}, b_1 = 0\right]$

2.1.112 Problem 114

Internal problem ID [9284]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 114
Date solved : `Monday, January 27, 2025 at 06:00:59 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$4x^2\left(x^2+1\right)y''+4x\left(6x^2+1\right)y'-\left(-25x^2+1\right)y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.282 (sec)

Writing the ode as

$$\left(4x^4+4x^2\right)y''+\left(24x^3+4x\right)y'+\left(25x^2-1\right)y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=4x^4+4x^2\\B&=24x^3+4x\\C&=25x^2-1\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned}r&=\frac{s}{t}\\&=\frac{2AB'-2BA'+B^2-4AC}{4A^2}\end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{-x^2-6}{4\left(x^2+1\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned}s&=-x^2-6\\t&=4\left(x^2+1\right)^2\end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{-x^2-6}{4\left(x^2+1\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.208: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^2+1)^2$. There is a pole at $x = i$ of order 2. There is a pole at $x = -i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{5}{16\,(x-i)^2} + \frac{5}{16\,(x+i)^2} + \frac{7i}{16\,(x-i)} - \frac{7i}{16\,(x+i)}$$

For the pole at $x = i$ let b be the coefficient of $\frac{1}{(x-i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{5}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{4} \end{aligned}$$

For the pole at $x = -i$ let b be the coefficient of $\frac{1}{(x+i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{5}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{4} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{-x^2 - 6}{4\left(x^2+1\right)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{1}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= 0\\ \alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2}\\ \alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{-x^2 - 6}{4\left(x^2+1\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
i	2	0	$\frac{5}{4}$	$-\frac{1}{4}$
$-i$	2	0	$\frac{5}{4}$	$-\frac{1}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$\begin{aligned}d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^-\right)\\ &= \frac{1}{2} - \left(-\frac{1}{2}\right)\\ &= 1\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2}\right) + (-)[\sqrt{r}]_\infty\\ &= -\frac{1}{4(x-i)} - \frac{1}{4(x+i)} + (-)(0)\\ &= -\frac{1}{4(x-i)} - \frac{1}{4(x+i)}\\ &= -\frac{x}{2x^2+2}\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{4(x-i)} - \frac{1}{4(x+i)}\right)(1) + \left(\left(\frac{1}{4(x-i)^2} + \frac{1}{4(x+i)^2}\right) + \left(-\frac{1}{4(x-i)} - \frac{1}{4(x+i)}\right)^2 - \left(\frac{-}{4(\cdots} \right.\right.$$

$$\frac{(x^2+1 \cdots}{(-x+i)^2 (\cdots}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx} \\
&= (x)\, e^{\int \left(-\frac{1}{4(x-i)} - \frac{1}{4(x+i)}\right) dx} \\
&= (x) \frac{1}{\left((-x+i)(x+i)\right)^{1/4}} \\
&= \frac{x}{\left(-x^2-1\right)^{1/4}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{24x^3+4x}{4x^4+4x^2}\, dx} \\
&= z_1 e^{-\frac{\ln(x)}{2} - \frac{5\ln\left(x^2+1\right)}{4}} \\
&= z_1 \left(\frac{1}{\sqrt{x}\left(x^2+1\right)^{5/4}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{\left(\frac{1}{2} - \frac{i}{2}\right)\sqrt{x}\,\sqrt{2}}{\left(x^2+1\right)^{3/2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{24x^3+4x}{4x^4+4x^2}\, dx}}{\left(y_1\right)^2}\, dx \\
&= y_1 \int \frac{e^{-\ln(x) - \frac{5\ln\left(x^2+1\right)}{2}}}{\left(y_1\right)^2}\, dx \\
&= y_1 \left(i\left(-\frac{\left(x^2+1\right)^{3/2}}{x} + x\sqrt{x^2+1} + \operatorname{arcsinh}(x)\right)\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\frac{\left(\frac{1}{2} - \frac{i}{2}\right) \sqrt{x}\, \sqrt{2}}{\left(x^2+1\right)^{3/2}} \right) \\ &\quad + c_2 \left(\frac{\left(\frac{1}{2} - \frac{i}{2}\right) \sqrt{x}\, \sqrt{2}}{\left(x^2+1\right)^{3/2}} \left(i \left(-\frac{\left(x^2+1\right)^{3/2}}{x} + x\sqrt{x^2+1} + \operatorname{arcsinh}(x) \right) \right) \right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$4x^2(x^2+1)\left(\frac{d^2}{dx^2}y(x)\right) + 4x(6x^2+1)\left(\frac{d}{dx}y(x)\right) - (-25x^2+1)\, y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

    $x_0 = 0$

- Multiply by denominators

  $4x^2(x^2+1)\left(\frac{d^2}{dx^2}y(x)\right) + 4x(6x^2+1)\left(\frac{d}{dx}y(x)\right) + (25x^2-1)\, y(x) = 0$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $x^m \cdot y(x)$ to series expansion for $m = 0..2$

    $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

  ◦ Shift index using $k- >k-m$

    $x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

  ◦ Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m = 1..3$

$$x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1+m}$$

- Shift index using $k- >k+1-m$

$$x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$$

- Convert $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m = 2..4$

$$x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-2+m}$$

- Shift index using $k- >k+2-m$

$$x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0(1+2r)\,(-1+2r)\, x^r + a_1(3+2r)\,(1+2r)\, x^{1+r} + \left(\sum_{k=2}^{\infty} (a_k(2k+2r+1)\,(2k+2r-1) + a_{k-2}$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $(1+2r)\,(-1+2r) = 0$
- Values of r that satisfy the indicial equation
  $r \in \left\{-\frac{1}{2}, \frac{1}{2}\right\}$
- Each term must be 0
  $a_1(3+2r)\,(1+2r) = 0$
- Solve for the dependent coefficient(s)
  $a_1 = 0$
- Each term in the series must be 0, giving the recursion relation
  $4\left(k+r+\frac{1}{2}\right)\left(\left(k+r+\frac{1}{2}\right)a_{k-2} + \left(k+r-\frac{1}{2}\right)a_k\right) = 0$
- Shift index using $k- >k+2$
  $4\left(k+\frac{5}{2}+r\right)\left(\left(k+\frac{5}{2}+r\right)a_k + \left(k+\frac{3}{2}+r\right)a_{k+2}\right) = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+2} = -\frac{(2k+2r+5)a_k}{2k+3+2r}$
- Recursion relation for $r = -\frac{1}{2}$
  $a_{k+2} = -\frac{(2k+4)a_k}{2k+2}$
- Solution for $r = -\frac{1}{2}$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k-\frac{1}{2}}, a_{k+2} = -\frac{(2k+4)a_k}{2k+2}, a_1 = 0\right]$
- Recursion relation for $r = \frac{1}{2}$
  $a_{k+2} = -\frac{(2k+6)a_k}{2k+4}$
- Solution for $r = \frac{1}{2}$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}, a_{k+2} = -\frac{(2k+6)a_k}{2k+4}, a_1 = 0\right]$
- Combine solutions and rename parameters
  $\left[y(x) = \left(\sum_{k=0}^{\infty} a_k x^{k-\frac{1}{2}}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{2}}\right), a_{k+2} = -\frac{(2k+4)a_k}{2k+2}, a_1 = 0, b_{k+2} = -\frac{b_k(2k+6)}{2k+4}, b_1 = 0\right]$

2.1.113 Problem 115

Internal problem ID [9285]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 115
Date solved : `Monday, January 27, 2025 at 06:01:00 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$8x^2\left(2x^2+1\right)y''+2x\left(34x^2+5\right)y'-\left(-30x^2+1\right)y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.478 (sec)

Writing the ode as

$$\left(16x^4+8x^2\right)y''+\left(68x^3+10x\right)y'+\left(30x^2-1\right)y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 16x^4+8x^2 \\ B &= 68x^3+10x \\ C &= 30x^2-1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r=\frac{132x^4+148x^2-7}{64\left(2x^3+x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 132x^4+148x^2-7 \\ t &= 64\left(2x^3+x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{132x^4+148x^2-7}{64\left(2x^3+x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.210: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 4 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 64(2x^3 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = \frac{i\sqrt{2}}{2}$ of order 2. There is a pole at $x = -\frac{i\sqrt{2}}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{3}{16\left(x - \frac{i\sqrt{2}}{2}\right)^2} - \frac{3}{16\left(x + \frac{i\sqrt{2}}{2}\right)^2} - \frac{i\sqrt{2}}{2\left(x - \frac{i\sqrt{2}}{2}\right)} + \frac{i\sqrt{2}}{2x + i\sqrt{2}} - \frac{7}{64x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{7}{64}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{7}{8} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{8} \end{aligned}$$

For the pole at $x = \frac{i\sqrt{2}}{2}$ let b be the coefficient of $\frac{1}{\left(x-\frac{i\sqrt{2}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0\\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{4}\\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{4}
\end{aligned}$$

For the pole at $x = -\frac{i\sqrt{2}}{2}$ let b be the coefficient of $\frac{1}{\left(x+\frac{i\sqrt{2}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0\\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{4}\\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{4}
\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{132x^4 + 148x^2 - 7}{64\left(2x^3 + x\right)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{33}{64}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0\\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{11}{8}\\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{8}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{132x^4 + 148x^2 - 7}{64\left(2x^3 + x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{7}{8}$	$\frac{1}{8}$
$\frac{i\sqrt{2}}{2}$	2	0	$\frac{3}{4}$	$\frac{1}{4}$
$-\frac{i\sqrt{2}}{2}$	2	0	$\frac{3}{4}$	$\frac{1}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{11}{8}$	$-\frac{3}{8}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{11}{8}$ then

$$\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^+ + \alpha_{c_2}^- + \alpha_{c_3}^-\right)\\
&= \frac{11}{8} - \left(\frac{11}{8}\right)\\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x-c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{-}}{x-c_2} \right) + \left((-)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^{-}}{x-c_3} \right) + (+)[\sqrt{r}]_\infty \\
&= \frac{7}{8x} + \frac{1}{4x-2i\sqrt{2}} + \frac{1}{4x+2i\sqrt{2}} + (0) \\
&= \frac{7}{8x} + \frac{1}{4x-2i\sqrt{2}} + \frac{1}{4x+2i\sqrt{2}} \\
&= \frac{22x^2+7}{16x^3+8x}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{7}{8x} + \frac{1}{4x-2i\sqrt{2}} + \frac{1}{4x+2i\sqrt{2}} \right)(0) + \left(\left(-\frac{7}{8x^2} - \frac{1}{4\left(x - \frac{i\sqrt{2}}{2}\right)^2} - \frac{1}{4\left(x + \frac{i\sqrt{2}}{2}\right)^2} \right) + \left(\frac{7}{8x} + \frac{1}{4x -}\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx} \\
&= e^{\int \left(\frac{7}{8x} + \frac{1}{4x-2i\sqrt{2}} + \frac{1}{4x+2i\sqrt{2}} \right) dx} \\
&= 2^{1/4} \left(2x^2+1 \right)^{1/4} x^{7/8}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{68x^3+10x}{16x^4+8x^2}\, dx} \\
&= z_1 e^{-\frac{5\ln(x)}{8} - \frac{3\ln\left(2x^2+1\right)}{4}} \\
&= z_1 \left(\frac{1}{x^{5/8} \left(2x^2+1\right)^{3/4}} \right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{x^{1/4} 2^{1/4}}{\sqrt{2x^2+1}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{68x^3+10x}{16x^4+8x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{5\ln(x)}{4}-\frac{3\ln(2x^2+1)}{2}}}{(y_1)^2}\,dx \\
&= y_1 \left(\int \frac{\mathrm{e}^{-\frac{5\ln(x)}{4}-\frac{3\ln(2x^2+1)}{2}}(2x^2+1)\sqrt{2}}{2\sqrt{x}}dx\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{x^{1/4}2^{1/4}}{\sqrt{2x^2+1}}\right) + c_2\left(\frac{x^{1/4}2^{1/4}}{\sqrt{2x^2+1}}\left(\int \frac{\mathrm{e}^{-\frac{5\ln(x)}{4}-\frac{3\ln(2x^2+1)}{2}}(2x^2+1)\sqrt{2}}{2\sqrt{x}}dx\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve
$8x^2(2x^2+1)\left(\frac{d^2}{dx^2}y(x)\right)+2x(34x^2+5)\left(\frac{d}{dx}y(x)\right)-(-30x^2+1)\,y(x)=0$

- Highest derivative means the order of the ODE is 2
  $\frac{d^2}{dx^2}y(x)$
- Isolate 2nd derivative
  $\frac{d^2}{dx^2}y(x)=-\frac{(30x^2-1)y(x)}{8x^2(2x^2+1)}-\frac{(34x^2+5)\left(\frac{d}{dx}y(x)\right)}{4x(2x^2+1)}$
- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin
  $\frac{d^2}{dx^2}y(x)+\frac{(34x^2+5)\left(\frac{d}{dx}y(x)\right)}{4x(2x^2+1)}+\frac{(30x^2-1)y(x)}{8x^2(2x^2+1)}=0$

☐ Check to see if x_0 is a regular singular point
  - Define functions
    $\left[P_2(x)=\frac{34x^2+5}{4x(2x^2+1)}, P_3(x)=\frac{30x^2-1}{8x^2(2x^2+1)}\right]$
  - $x\cdot P_2(x)$ is analytic at $x=0$
    $\left.(x\cdot P_2(x))\right|_{x=0}=\frac{5}{4}$
  - $x^2\cdot P_3(x)$ is analytic at $x=0$
    $\left.(x^2\cdot P_3(x))\right|_{x=0}=-\frac{1}{8}$
  - $x=0$is a regular singular point

  Check to see if x_0 is a regular singular point
  $x_0=0$

- Multiply by denominators
  $8x^2(2x^2+1)\left(\frac{d^2}{dx^2}y(x)\right)+2x(34x^2+5)\left(\frac{d}{dx}y(x)\right)+(30x^2-1)\,y(x)=0$
- Assume series solution for $y(x)$
  $y(x)=\sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $x^m \cdot y(x)$ to series expansion for $m = 0..2$

$$x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$$

- Shift index using $k- > k - m$

$$x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$$

- Convert $x^m \cdot \left(\frac{d}{dx} y(x)\right)$ to series expansion for $m = 1..3$

$$x^m \cdot \left(\frac{d}{dx} y(x)\right) = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r-1+m}$$

- Shift index using $k- > k + 1 - m$

$$x^m \cdot \left(\frac{d}{dx} y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m} (k+1-m+r)\, x^{k+r}$$

- Convert $x^m \cdot \left(\frac{d^2}{dx^2} y(x)\right)$ to series expansion for $m = 2..4$

$$x^m \cdot \left(\frac{d^2}{dx^2} y(x)\right) = \sum_{k=0}^{\infty} a_k (k+r)(k+r-1)\, x^{k+r-2+m}$$

- Shift index using $k- > k + 2 - m$

$$x^m \cdot \left(\frac{d^2}{dx^2} y(x)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m} (k+2-m+r)(k+1-m+r)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0(1+2r)(-1+4r)\, x^r + a_1(3+2r)(3+4r)\, x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(2k+2r+1)(4k+4r-1) + 2a_{k-2}(2\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
$(1+2r)(-1+4r) = 0$
- Values of r that satisfy the indicial equation
$r \in \left\{-\frac{1}{2}, \frac{1}{4}\right\}$
- Each term must be 0
$a_1(3+2r)(3+4r) = 0$
- Solve for the dependent coefficient(s)
$a_1 = 0$
- Each term in the series must be 0, giving the recursion relation
$8\left(\left(2k+2r-\frac{5}{2}\right) a_{k-2} + a_k\left(k+r-\frac{1}{4}\right)\right)\left(k+r+\frac{1}{2}\right) = 0$
- Shift index using $k- > k + 2$
$8\left(\left(2k+\frac{3}{2}+2r\right) a_k + a_{k+2}\left(k+\frac{7}{4}+r\right)\right)\left(k+\frac{5}{2}+r\right) = 0$
- Recursion relation that defines series solution to ODE
$a_{k+2} = -\frac{2(4k+4r+3)a_k}{4k+7+4r}$
- Recursion relation for $r = -\frac{1}{2}$
$a_{k+2} = -\frac{2(4k+1)a_k}{4k+5}$
- Solution for $r = -\frac{1}{2}$
$\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k-\frac{1}{2}}, a_{k+2} = -\frac{2(4k+1)a_k}{4k+5}, a_1 = 0\right]$
- Recursion relation for $r = \frac{1}{4}$
$a_{k+2} = -\frac{2(4k+4)a_k}{4k+8}$
- Solution for $r = \frac{1}{4}$
$\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{4}}, a_{k+2} = -\frac{2(4k+4)a_k}{4k+8}, a_1 = 0\right]$
- Combine solutions and rename parameters

$$\left[y(x)=\left(\sum_{k=0}^{\infty} a_k x^{k-\frac{1}{2}}\right)+\left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{4}}\right), a_{k+2}=-\frac{2(4k+1)a_k}{4k+5}, a_1=0, b_{k+2}=-\frac{2(4k+4)b_k}{4k+8}, b_1=0\right]$$

2.1.114 Problem 116

Internal problem ID [9286]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 116
Date solved : `Monday, January 27, 2025 at 06:01:01 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$2x^2(1+x)\,y''-x(1-3x)\,y'+y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.153 (sec)

Writing the ode as

$$\left(2x^3+2x^2\right)y''+\left(3x^2-x\right)y'+y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2x^3+2x^2 \\ B &= 3x^2-x \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{-3}{16x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -3 \\ t &= 16x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(-\frac{3}{16x^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.212: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{3}{16x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{4} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = -\frac{3}{16x^2}$$

Since the gcd$(s,t)=1$. This gives $b=-\frac{3}{16}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2}+\sqrt{1+4b}=\frac{3}{4} \\
\alpha_\infty^- &= \frac{1}{2}-\sqrt{1+4b}=\frac{1}{4}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r=-\frac{3}{16x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{3}{4}$	$\frac{1}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{3}{4}$	$\frac{1}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^-=\frac{1}{4}$ then

$$
\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\
&= \frac{1}{4}-\left(\frac{1}{4}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$
\omega=\sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c+\frac{\alpha_c^{s(c)}}{x-c}\right)+s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1}+\frac{\alpha_{c_1}^-}{x-c_1}\right)+(-)[\sqrt{r}]_\infty \\
&= \frac{1}{4x}+(-)\,(0) \\
&= \frac{1}{4x} \\
&= \frac{1}{4x}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p''+2\omega p'+\left(\omega'+\omega^2-r\right)p=0 \tag{1A}
$$

Let

$$
p(x)=1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(\frac{1}{4x}\right)(0)+\left(\left(-\frac{1}{4x^2}\right)+\left(\frac{1}{4x}\right)^2-\left(-\frac{3}{16x^2}\right)\right)=0$$
$$0=0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z''=rz$ is

$$\begin{aligned} z_1(x) &= pe^{\int \omega\, dx} \\ &= \mathrm{e}^{\int \frac{1}{4x} dx} \\ &= x^{1/4} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{3x^2-x}{2x^3+2x^2}\, dx} \\ &= z_1 e^{\frac{\ln(x)}{4}-\ln(1+x)} \\ &= z_1\left(\frac{x^{1/4}}{1+x}\right) \end{aligned}$$

Which simplifies to

$$y_1=\frac{\sqrt{x}}{1+x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2=y_1\int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1\int \frac{e^{\int -\frac{3x^2-x}{2x^3+2x^2}\, dx}}{(y_1)^2}\, dx \\ &= y_1\int \frac{e^{\frac{\ln(x)}{2}-2\ln(1+x)}}{(y_1)^2}\, dx \\ &= y_1\left(2\,\mathrm{e}^{\frac{\ln(x)}{2}-2\ln(1+x)}(1+x)^2\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\frac{\sqrt{x}}{1+x}\right)+c_2\left(\frac{\sqrt{x}}{1+x}\left(2\,\mathrm{e}^{\frac{\ln(x)}{2}-2\ln(1+x)}(1+x)^2\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$2x^2(x+1)\left(\frac{d^2}{dx^2}y(x)\right) - x(1-3x)\left(\frac{d}{dx}y(x)\right) + y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{y(x)}{2(x+1)x^2} - \frac{(3x-1)\left(\frac{d}{dx}y(x)\right)}{2x(x+1)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x) + \frac{(3x-1)\left(\frac{d}{dx}y(x)\right)}{2x(x+1)} + \frac{y(x)}{2(x+1)x^2} = 0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

    $\left[P_2(x) = \frac{3x-1}{2x(x+1)}, P_3(x) = \frac{1}{2(x+1)x^2}\right]$

  ◦ $(x+1)\cdot P_2(x)$ is analytic at $x=-1$

    $\left((x+1)\cdot P_2(x)\right)\Big|_{x=-1} = 2$

  ◦ $(x+1)^2\cdot P_3(x)$ is analytic at $x=-1$

    $\left((x+1)^2\cdot P_3(x)\right)\Big|_{x=-1} = 0$

  ◦ $x=-1$is a regular singular point

    Check to see if x_0 is a regular singular point

    $x_0 = -1$

- Multiply by denominators

  $2x^2(x+1)\left(\frac{d^2}{dx^2}y(x)\right) + x(3x-1)\left(\frac{d}{dx}y(x)\right) + y(x) = 0$

- Change variables using $x = u-1$ so that the regular singular point is at $u=0$

  $(2u^3-4u^2+2u)\left(\frac{d^2}{du^2}y(u)\right) + (3u^2-7u+4)\left(\frac{d}{du}y(u)\right) + y(u) = 0$

- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..2$

    $u^m\cdot\left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,u^{k+r-1+m}$

  ◦ Shift index using $k->k+1-m$

    $u^m\cdot\left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,u^{k+r}$

  ◦ Convert $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m=1..3$

    $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\,u^{k+r-2+m}$

  ◦ Shift index using $k->k+2-m$

    $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\,u^{k+r}$

  Rewrite ODE with series expansions

  $2a_0r(1+r)\,u^{-1+r} + \left(2a_1(1+r)(2+r) - a_0(1+r)(-1+4r)\right)u^r + \left(\sum_{k=1}^{\infty} (2a_{k+1}(k+r+1)(k+\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$2r(1+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{-1, 0\}$

- Each term must be 0

  $2a_1(1+r)(2+r) - a_0(1+r)(-1+4r) = 0$

- Each term in the series must be 0, giving the recursion relation

  $(-4a_k + 2a_{k-1} + 2a_{k+1})k^2 + ((-8a_k + 4a_{k-1} + 4a_{k+1})r - 3a_k - 3a_{k-1} + 6a_{k+1})k + (-4a_k + 2a_{k-}$

- Shift index using $k- > k+1$

  $(-4a_{k+1} + 2a_k + 2a_{k+2})(k+1)^2 + ((-8a_{k+1} + 4a_k + 4a_{k+2})r - 3a_{k+1} - 3a_k + 6a_{k+2})(k+1) + (-$

- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{2k^2a_k - 4k^2a_{k+1} + 4kra_k - 8kra_{k+1} + 2r^2a_k - 4r^2a_{k+1} + ka_k - 11ka_{k+1} + ra_k - 11ra_{k+1} - 6a_{k+1}}{2(k^2 + 2kr + r^2 + 5k + 5r + 6)}$

- Recursion relation for $r = -1$

  $a_{k+2} = -\frac{2k^2a_k - 4k^2a_{k+1} - 3ka_k - 3ka_{k+1} + a_k + a_{k+1}}{2(k^2 + 3k + 2)}$

- Solution for $r = -1$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k-1}, a_{k+2} = -\frac{2k^2a_k - 4k^2a_{k+1} - 3ka_k - 3ka_{k+1} + a_k + a_{k+1}}{2(k^2 + 3k + 2)}, 0 = 0\right]$

- Revert the change of variables $u = x + 1$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k (x+1)^{k-1}, a_{k+2} = -\frac{2k^2a_k - 4k^2a_{k+1} - 3ka_k - 3ka_{k+1} + a_k + a_{k+1}}{2(k^2 + 3k + 2)}, 0 = 0\right]$

- Recursion relation for $r = 0$

  $a_{k+2} = -\frac{2k^2a_k - 4k^2a_{k+1} + ka_k - 11ka_{k+1} - 6a_{k+1}}{2(k^2 + 5k + 6)}$

- Solution for $r = 0$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+2} = -\frac{2k^2a_k - 4k^2a_{k+1} + ka_k - 11ka_{k+1} - 6a_{k+1}}{2(k^2 + 5k + 6)}, 4a_1 + a_0 = 0\right]$

- Revert the change of variables $u = x + 1$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k (x+1)^k, a_{k+2} = -\frac{2k^2a_k - 4k^2a_{k+1} + ka_k - 11ka_{k+1} - 6a_{k+1}}{2(k^2 + 5k + 6)}, 4a_1 + a_0 = 0\right]$

- Combine solutions and rename parameters

  $\left[y(x) = \left(\sum_{k=0}^{\infty} a_k (x+1)^{k-1}\right) + \left(\sum_{k=0}^{\infty} b_k (x+1)^k\right), a_{k+2} = -\frac{2k^2a_k - 4k^2a_{k+1} - 3ka_k - 3ka_{k+1} + a_k + a_{k+1}}{2(k^2 + 3k + 2)}, 0 = 0,$

2.1.115 Problem 117

Internal problem ID [9287]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 117
Date solved : `Monday, January 27, 2025 at 06:01:02 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$6x^2\left(2x^2+1\right)y''+x\left(50x^2+1\right)y'+\left(30x^2+1\right)y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.164 (sec)

Writing the ode as

$$\left(12x^4+6x^2\right)y''+\left(50x^3+x\right)y'+\left(30x^2+1\right)y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 12x^4+6x^2 \\ B &= 50x^3+x \\ C &= 30x^2+1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{-35}{144x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -35 \\ t &= 144x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(-\frac{35}{144x^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.214: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 144x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{35}{144x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{35}{144}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{12} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{5}{12} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = -\frac{35}{144x^2}$$

Since the $\gcd(s,t)=1$. This gives $b=-\frac{35}{144}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0\\
\alpha_\infty^{+} &= \frac{1}{2}+\sqrt{1+4b}=\frac{7}{12}\\
\alpha_\infty^{-} &= \frac{1}{2}-\sqrt{1+4b}=\frac{5}{12}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r=-\frac{35}{144x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{7}{12}$	$\frac{5}{12}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{7}{12}$	$\frac{5}{12}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-}=\frac{5}{12}$ then

$$\begin{aligned}
d &= \alpha_\infty^{-}-\left(\alpha_{c_1}^{-}\right)\\
&= \frac{5}{12}-\left(\frac{5}{12}\right)\\
&= 0
\end{aligned}$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$\omega=\sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c+\frac{\alpha_c^{s(c)}}{x-c}\right)+s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1}+\frac{\alpha_{c_1}^{-}}{x-c_1}\right)+(-)[\sqrt{r}]_\infty\\
&= \frac{5}{12x}+(-)\,(0)\\
&= \frac{5}{12x}\\
&= \frac{5}{12x}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p''+2\omega p'+\left(\omega'+\omega^2-r\right)p=0 \tag{1A}$$

Let

$$p(x)=1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(\frac{5}{12x}\right)(0)+\left(\left(-\frac{5}{12x^2}\right)+\left(\frac{5}{12x}\right)^2-\left(-\frac{35}{144x^2}\right)\right)=0$$
$$0=0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z''=rz$ is

$$\begin{aligned}z_1(x)&=pe^{\int \omega\,dx}\\&=e^{\int \frac{5}{12x}dx}\\&=x^{5/12}\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}y_1&=z_1e^{\int -\frac{1}{2}\frac{B}{A}\,dx}\\&=z_1e^{-\int \frac{1}{2}\frac{50x^3+x}{12x^4+6x^2}\,dx}\\&=z_1e^{-\ln(2x^2+1)-\frac{\ln(x)}{12}}\\&=z_1\left(\frac{1}{(2x^2+1)\,x^{1/12}}\right)\end{aligned}$$

Which simplifies to

$$y_1=\frac{x^{1/3}}{2x^2+1}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2=y_1\int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}y_2&=y_1\int \frac{e^{\int -\frac{50x^3+x}{12x^4+6x^2}\,dx}}{(y_1)^2}\,dx\\&=y_1\int \frac{e^{-2\ln(2x^2+1)-\frac{\ln(x)}{6}}}{(y_1)^2}\,dx\\&=y_1\left(6x^{1/3}e^{-2\ln(2x^2+1)-\frac{\ln(x)}{6}}\left(2x^2+1\right)^2\right)\end{aligned}$$

Therefore the solution is

$$\begin{aligned}y&=c_1y_1+c_2y_2\\&=c_1\left(\frac{x^{1/3}}{2x^2+1}\right)+c_2\left(\frac{x^{1/3}}{2x^2+1}\left(6x^{1/3}e^{-2\ln(2x^2+1)-\frac{\ln(x)}{6}}\left(2x^2+1\right)^2\right)\right)\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$6x^2(2x^2+1)\left(\frac{d^2}{dx^2}y(x)\right)+x(50x^2+1)\left(\frac{d}{dx}y(x)\right)+(30x^2+1)\,y(x)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x)=-\frac{(30x^2+1)y(x)}{6x^2(2x^2+1)}-\frac{(50x^2+1)\left(\frac{d}{dx}y(x)\right)}{6x(2x^2+1)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x)+\frac{(50x^2+1)\left(\frac{d}{dx}y(x)\right)}{6x(2x^2+1)}+\frac{(30x^2+1)y(x)}{6x^2(2x^2+1)}=0$

- □ Check to see if x_0 is a regular singular point

2.1.116 Problem 118

Internal problem ID [9288]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 118
Date solved : `Monday, January 27, 2025 at 06:01:02 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$28x^2(1-3x)\,y''-7x(5+9x)\,y'+7(2+9x)\,y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.157 (sec)

Writing the ode as

$$\left(-84x^3+28x^2\right)y''+\left(-63x^2-35x\right)y'+(63x+14)\,y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= -84x^3+28x^2\\ B &= -63x^2-35x\\ C &= 63x+14 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{33}{64x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 33\\ t &= 64x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{33}{64x^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.216: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 64x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{33}{64x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{33}{64}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{11}{8} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{8} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{33}{64x^2}$$

Since the gcd$(s,t)=1$. This gives $b=\frac{33}{64}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2}+\sqrt{1+4b}=\frac{11}{8} \\
\alpha_\infty^- &= \frac{1}{2}-\sqrt{1+4b}=-\frac{3}{8}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r=\frac{33}{64x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{11}{8}$	$-\frac{3}{8}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{11}{8}$	$-\frac{3}{8}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^-=-\frac{3}{8}$ then

$$
\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\
&= -\frac{3}{8}-\left(-\frac{3}{8}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$
\omega=\sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c+\frac{\alpha_c^{s(c)}}{x-c}\right)+s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1}+\frac{\alpha_{c_1}^-}{x-c_1}\right)+(-)[\sqrt{r}]_\infty \\
&= -\frac{3}{8x}+(-)(0) \\
&= -\frac{3}{8x} \\
&= -\frac{3}{8x}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p''+2\omega p'+\left(\omega'+\omega^2-r\right)p=0 \tag{1A}
$$

Let

$$
p(x)=1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{3}{8x}\right)(0) + \left(\left(\frac{3}{8x^2}\right) + \left(-\frac{3}{8x}\right)^2 - \left(\frac{33}{64x^2}\right)\right) = 0$$
$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= e^{\int -\frac{3}{8x} dx} \\ &= \frac{1}{x^{3/8}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2} \frac{-63x^2 - 35x}{-84x^3 + 28x^2} \, dx} \\ &= z_1 e^{\frac{5 \ln(x)}{8} - \ln(-1+3x)} \\ &= z_1 \left(\frac{x^{5/8}}{-1+3x}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{x^{1/4}}{-1+3x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-63x^2 - 35x}{-84x^3 + 28x^2} \, dx}}{(y_1)^2} \, dx \\ &= y_1 \int \frac{e^{\frac{5 \ln(x)}{4} - 2\ln(-1+3x)}}{(y_1)^2} \, dx \\ &= y_1 \left(\frac{4\sqrt{x}\, e^{\frac{5 \ln(x)}{4} - 2\ln(-1+3x)} (-1+3x)^2}{7}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\frac{x^{1/4}}{-1+3x}\right) + c_2 \left(\frac{x^{1/4}}{-1+3x} \left(\frac{4\sqrt{x}\, e^{\frac{5 \ln(x)}{4} - 2\ln(-1+3x)} (-1+3x)^2}{7}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$28x^2(1-3x)\left(\frac{d^2}{dx^2}y(x)\right)-7x(5+9x)\left(\frac{d}{dx}y(x)\right)+7(2+9x)\,y(x)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$
- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x)=\frac{(2+9x)y(x)}{4(3x-1)x^2}-\frac{(5+9x)\left(\frac{d}{dx}y(x)\right)}{4x(3x-1)}$
- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x)+\frac{(5+9x)\left(\frac{d}{dx}y(x)\right)}{4x(3x-1)}-\frac{(2+9x)y(x)}{4(3x-1)x^2}=0$

□ Check to see if x_0 is a regular singular point

- Define functions

  $\left[P_2(x)=\frac{5+9x}{4x(3x-1)},P_3(x)=-\frac{2+9x}{4(3x-1)x^2}\right]$
- $x\cdot P_2(x)$ is analytic at $x=0$

  $\left(x\cdot P_2(x)\right)\bigg|_{x=0}=-\frac{5}{4}$
- $x^2\cdot P_3(x)$ is analytic at $x=0$

  $\left(x^2\cdot P_3(x)\right)\bigg|_{x=0}=\frac{1}{2}$
- $x=0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=0$

- Multiply by denominators

  $4(3x-1)\,x^2\left(\frac{d^2}{dx^2}y(x)\right)+x(5+9x)\left(\frac{d}{dx}y(x)\right)+(-9x-2)\,y(x)=0$
- Assume series solution for $y(x)$

  $y(x)=\sum_{k=0}^{\infty}a_k x^{k+r}$

□ Rewrite ODE with series expansions

- Convert $x^m\cdot y(x)$ to series expansion for $m=0..1$

  $x^m\cdot y(x)=\sum_{k=0}^{\infty}a_k x^{k+r+m}$
- Shift index using $k->k-m$

  $x^m\cdot y(x)=\sum_{k=m}^{\infty}a_{k-m}x^{k+r}$
- Convert $x^m\cdot\left(\frac{d}{dx}y(x)\right)$ to series expansion for $m=1..2$

  $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,x^{k+r-1+m}$
- Shift index using $k->k+1-m$

  $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,x^{k+r}$
- Convert $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m=2..3$

  $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,x^{k+r-2+m}$
- Shift index using $k->k+2-m$

  $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=-2+m}^{\infty}a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$

  Rewrite ODE with series expansions

$$-a_0(-1+4r)(-2+r)x^r + \left(\sum_{k=1}^{\infty} \left(-a_k(4k+4r-1)(k+r-2) + 3a_{k-1}(4k+4r-1)(k+r-2)\right)\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $-(-1+4r)(-2+r) = 0$
- Values of r that satisfy the indicial equation
  $r \in \left\{2, \frac{1}{4}\right\}$
- Each term in the series must be 0, giving the recursion relation
  $-4(a_k - 3a_{k-1})\left(k+r-\frac{1}{4}\right)(k+r-2) = 0$
- Shift index using $k->k+1$
  $-4(a_{k+1} - 3a_k)\left(k+\frac{3}{4}+r\right)(k+r-1) = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+1} = 3a_k$
- Recursion relation for $r = 2$
  $a_{k+1} = 3a_k$
- Solution for $r = 2$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+2}, a_{k+1} = 3a_k\right]$
- Recursion relation for $r = \frac{1}{4}$
  $a_{k+1} = 3a_k$
- Solution for $r = \frac{1}{4}$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{4}}, a_{k+1} = 3a_k\right]$
- Combine solutions and rename parameters
  $\left[y(x) = \left(\sum_{k=0}^{\infty} a_k x^{k+2}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{4}}\right), a_{k+1} = 3a_k, b_{k+1} = 3b_k\right]$

CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$8x^2\left(-x^2+2\right)y''+2x\left(-21x^2+10\right)y'-\left(35x^2+2\right)y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.154 (sec)

Writing the ode as

$$\left(-8x^4+16x^2\right)y''+\left(-42x^3+20x\right)y'+\left(-35x^2-2\right)y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= -8x^4+16x^2 \\ B &= -42x^3+20x \\ C &= -35x^2-2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{-7}{64x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -7 \\ t &= 64x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(-\frac{7}{64x^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.218: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 64x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{7}{64x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{7}{64}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{8} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{8} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = -\frac{7}{64x^2}$$

Since the $\gcd(s,t)=1$. This gives $b=-\frac{7}{64}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2}+\sqrt{1+4b}=\frac{7}{8} \\
\alpha_\infty^- &= \frac{1}{2}-\sqrt{1+4b}=\frac{1}{8}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r=-\frac{7}{64x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{7}{8}$	$\frac{1}{8}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{7}{8}$	$\frac{1}{8}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^-=\frac{1}{8}$ then

$$
\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\
&= \frac{1}{8}-\left(\frac{1}{8}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$
\omega=\sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c+\frac{\alpha_c^{s(c)}}{x-c}\right)+s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1}+\frac{\alpha_{c_1}^-}{x-c_1}\right)+(-)[\sqrt{r}]_\infty \\
&= \frac{1}{8x}+(-)(0) \\
&= \frac{1}{8x} \\
&= \frac{1}{8x}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p''+2\omega p'+\left(\omega'+\omega^2-r\right)p=0 \tag{1A}
$$

Let

$$
p(x)=1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{8x}\right)(0) + \left(\left(-\frac{1}{8x^2}\right) + \left(\frac{1}{8x}\right)^2 - \left(-\frac{7}{64x^2}\right)\right) = 0$$
$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= e^{\int \frac{1}{8x} dx} \\ &= x^{1/8} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-42x^3+20x}{-8x^4+16x^2} dx} \\ &= z_1 e^{-\ln(x^2-2)-\frac{5\ln(x)}{8}} \\ &= z_1 \left(\frac{1}{(x^2-2)\, x^{5/8}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{1}{(x^2-2)\sqrt{x}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-42x^3+20x}{-8x^4+16x^2} dx}}{(y_1)^2} \, dx \\ &= y_1 \int \frac{e^{-2\ln(x^2-2)-\frac{5\ln(x)}{4}}}{(y_1)^2} \, dx \\ &= y_1 \left(\frac{4x^2 e^{-2\ln(x^2-2)-\frac{5\ln(x)}{4}} (x^2-2)^2}{3}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\frac{1}{(x^2-2)\sqrt{x}}\right) + c_2\left(\frac{1}{(x^2-2)\sqrt{x}}\left(\frac{4x^2 e^{-2\ln(x^2-2)-\frac{5\ln(x)}{4}} (x^2-2)^2}{3}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$8x^2(-x^2+2)\left(\frac{d^2}{dx^2}y(x)\right)+2x(-21x^2+10)\left(\frac{d}{dx}y(x)\right)-(35x^2+2)\,y(x)=0$

- Highest derivative means the order of the ODE is 2

$\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

$\frac{d^2}{dx^2}y(x)=-\frac{(35x^2+2)y(x)}{8x^2(x^2-2)}-\frac{(21x^2-10)\left(\frac{d}{dx}y(x)\right)}{4x(x^2-2)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

$\frac{d^2}{dx^2}y(x)+\frac{(21x^2-10)\left(\frac{d}{dx}y(x)\right)}{4x(x^2-2)}+\frac{(35x^2+2)y(x)}{8x^2(x^2-2)}=0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

  $\left[P_2(x)=\frac{21x^2-10}{4x(x^2-2)}, P_3(x)=\frac{35x^2+2}{8x^2(x^2-2)}\right]$

  ◦ $x\cdot P_2(x)$ is analytic at $x=0$

  $\left.(x\cdot P_2(x))\right|_{x=0}=\frac{5}{4}$

  ◦ $x^2\cdot P_3(x)$ is analytic at $x=0$

  $\left.(x^2\cdot P_3(x))\right|_{x=0}=-\frac{1}{8}$

2.1.118 Problem 120

Internal problem ID [9290]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 120
Date solved : `Monday, January 27, 2025 at 06:01:03 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$4x^2\left(x^2+3x+1\right)y''-4x\left(-3x^2-3x+1\right)y'+3\left(x^2-x+1\right)y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.100 (sec)

Writing the ode as

$$\left(4x^4+12x^3+4x^2\right)y''+\left(12x^3+12x^2-4x\right)y'+\left(3x^2-3x+3\right)y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4x^4+12x^3+4x^2 \\ B &= 12x^3+12x^2-4x \\ C &= 3x^2-3x+3 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$s=0$$
$$t=1$$

Therefore eq. (4) becomes

$$z''(x)=0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.220: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{12x^3+12x^2-4x}{4x^4+12x^3+4x^2}\, dx} \\ &= z_1 e^{-\ln(x^2+3x+1)+\frac{\ln(x)}{2}} \\ &= z_1\left(\frac{\sqrt{x}}{x^2+3x+1}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{\sqrt{x}}{x^2+3x+1}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{12x^3+12x^2-4x}{4x^4+12x^3+4x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-2\ln(x^2+3x+1)+\ln(x)}}{(y_1)^2}\,dx \\
&= y_1(x)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{\sqrt{x}}{x^2+3x+1}\right) + c_2\left(\frac{\sqrt{x}}{x^2+3x+1}(x)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$4x^2(x^2+3x+1)\left(\frac{d^2}{dx^2}y(x)\right) - 4x(-3x^2-3x+1)\left(\frac{d}{dx}y(x)\right) + 3(x^2-x+1)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{3(x^2-x+1)y(x)}{4x^2(x^2+3x+1)} - \frac{(3x^2+3x-1)\left(\frac{d}{dx}y(x)\right)}{x(x^2+3x+1)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x) + \frac{(3x^2+3x-1)\left(\frac{d}{dx}y(x)\right)}{x(x^2+3x+1)} + \frac{3(x^2-x+1)y(x)}{4x^2(x^2+3x+1)} = 0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

    $\left.(x^2 \cdot P_3(x))\right|_{x=0} = \frac{3}{4}$

  ◦ $x = 0$is a regular singular point

    Check to see if x_0 is a regular singular point

    $x_0 = 0$

- Multiply by denominators

  $4x^2(x^2+3x+1)\left(\frac{d^2}{dx^2}y(x)\right) + 4x(3x^2+3x-1)\left(\frac{d}{dx}y(x)\right) + (3x^2-3x+3)\,y(x) = 0$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $x^m \cdot y(x)$ to series expansion for $m = 0..2$

    $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- Shift index using $k->k-m$

  $x^m \cdot y(x)=\sum_{k=m}^{\infty} a_{k-m} x^{k+r}$
- Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m=1..3$

  $x^m \cdot \left(\frac{d}{dx}y(x)\right)=\sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1+m}$
- Shift index using $k->k+1-m$

  $x^m \cdot \left(\frac{d}{dx}y(x)\right)=\sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$
- Convert $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m=2..4$

  $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-2+m}$
- Shift index using $k->k+2-m$

  $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(-1+2r)\,(-3+2r)\, x^r+\left(a_1(1+2r)\,(-1+2r)+3a_0(1+2r)\,(-1+2r)\right) x^{1+r}+\left(\sum_{k=2}^{\infty} (a_k(2k+2\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-1+2r)\,(-3+2r)=0$
- Values of r that satisfy the indicial equation

  $r\in\left\{\frac{1}{2},\frac{3}{2}\right\}$
- Each term must be 0

  $a_1(1+2r)\,(-1+2r)+3a_0(1+2r)\,(-1+2r)=0$
- Solve for the dependent coefficient(s)

  $a_1=-3a_0$
- Each term in the series must be 0, giving the recursion relation

  $(2k+2r-1)\,(2k+2r-3)\,(a_k+3a_{k-1}+a_{k-2})=0$
- Shift index using $k->k+2$

  $(2k+2r+3)\,(2k+2r+1)\,(a_{k+2}+3a_{k+1}+a_k)=0$
- Recursion relation that defines series solution to ODE

2.1.119 Problem 121

Internal problem ID [9291]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 121
Date solved : `Monday, January 27, 2025 at 06:01:04 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$3x^2(1+x)^2 y'' - x\left(-11x^2 - 10x + 1\right) y' + \left(5x^2 + 1\right) y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.148 (sec)

Writing the ode as

$$3x^2(1+x)^2 y'' + \left(11x^3 + 10x^2 - x\right) y' + \left(5x^2 + 1\right) y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 3x^2(1+x)^2 \\ B &= 11x^3 + 10x^2 - x \\ C &= 5x^2 + 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-5}{36x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -5 \\ t &= 36x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{5}{36x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.222: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 36x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{5}{36x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{5}{36}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{5}{6} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{6} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = -\frac{5}{36x^2}$$

Since the gcd$(s,t)=1$. This gives $b=-\frac{5}{36}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2}+\sqrt{1+4b}=\frac{5}{6} \\
\alpha_\infty^- &= \frac{1}{2}-\sqrt{1+4b}=\frac{1}{6}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r=-\frac{5}{36x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{5}{6}$	$\frac{1}{6}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{5}{6}$	$\frac{1}{6}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^-=\frac{1}{6}$ then

$$
\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\
&= \frac{1}{6}-\left(\frac{1}{6}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$
\omega=\sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c+\frac{\alpha_c^{s(c)}}{x-c}\right)+s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1}+\frac{\alpha_{c_1}^-}{x-c_1}\right)+(-)[\sqrt{r}]_\infty \\
&= \frac{1}{6x}+(-)\,(0) \\
&= \frac{1}{6x} \\
&= \frac{1}{6x}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p''+2\omega p'+\left(\omega'+\omega^2-r\right)p=0 \tag{1A}
$$

Let

$$
p(x)=1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(\frac{1}{6x}\right)(0)+\left(\left(-\frac{1}{6x^2}\right)+\left(\frac{1}{6x}\right)^2-\left(-\frac{5}{36x^2}\right)\right)=0$$
$$0=0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z''=rz$ is

$$\begin{aligned}z_1(x)&=pe^{\int \omega\,dx}\\&=\mathrm{e}^{\int \frac{1}{6x}dx}\\&=x^{1/6}\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}y_1&=z_1e^{\int -\frac{1}{2}\frac{B}{A}\,dx}\\&=z_1e^{-\int \frac{1}{2}\frac{11x^3+10x^2-x}{3x^2(1+x)^2}\,dx}\\&=z_1e^{-2\ln(1+x)+\frac{\ln(x)}{6}}\\&=z_1\left(\frac{x^{1/6}}{(1+x)^2}\right)\end{aligned}$$

Which simplifies to

$$y_1=\frac{x^{1/3}}{(1+x)^2}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2=y_1\int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}y_2&=y_1\int \frac{e^{\int -\frac{11x^3+10x^2-x}{3x^2(1+x)^2}\,dx}}{(y_1)^2}\,dx\\&=y_1\int \frac{e^{-4\ln(1+x)+\frac{\ln(x)}{3}}}{(y_1)^2}\,dx\\&=y_1\left(\frac{3x^{1/3}\mathrm{e}^{-4\ln(1+x)+\frac{\ln(x)}{3}}(1+x)^4}{2}\right)\end{aligned}$$

Therefore the solution is

$$\begin{aligned}y&=c_1y_1+c_2y_2\\&=c_1\left(\frac{x^{1/3}}{(1+x)^2}\right)+c_2\left(\frac{x^{1/3}}{(1+x)^2}\left(\frac{3x^{1/3}\mathrm{e}^{-4\ln(1+x)+\frac{\ln(x)}{3}}(1+x)^4}{2}\right)\right)\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$3x^2(x+1)^2\left(\frac{d^2}{dx^2}y(x)\right)-x(-11x^2-10x+1)\left(\frac{d}{dx}y(x)\right)+(5x^2+1)\,y(x)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x)=-\frac{(5x^2+1)y(x)}{3x^2(x+1)^2}-\frac{\left(\frac{d}{dx}y(x)\right)(11x-1)}{3x(x+1)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x)+\frac{\left(\frac{d}{dx}y(x)\right)(11x-1)}{3x(x+1)}+\frac{(5x^2+1)y(x)}{3x^2(x+1)^2}=0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

    $\left[P_2(x)=\frac{11x-1}{3x(x+1)},P_3(x)=\frac{5x^2+1}{3x^2(x+1)^2}\right]$

  ◦ $(x+1)\cdot P_2(x)$ is analytic at $x=-1$

    $\left.((x+1)\cdot P_2(x))\right|_{x=-1}=4$

  ◦ $(x+1)^2\cdot P_3(x)$ is analytic at $x=-1$

    $\left.((x+1)^2\cdot P_3(x))\right|_{x=-1}=2$

  ◦ $x=-1$is a regular singular point

    Check to see if x_0 is a regular singular point

    $x_0=-1$

- Multiply by denominators

  $3x^2(x+1)^2\left(\frac{d^2}{dx^2}y(x)\right)+x(x+1)(11x-1)\left(\frac{d}{dx}y(x)\right)+(5x^2+1)\,y(x)=0$

- Change variables using $x=u-1$ so that the regular singular point is at $u=0$

  $(3u^4-6u^3+3u^2)\left(\frac{d^2}{du^2}y(u)\right)+(11u^3-23u^2+12u)\left(\frac{d}{du}y(u)\right)+(5u^2-10u+6)\,y(u)=0$

- Assume series solution for $y(u)$

  $y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $u^m\cdot y(u)$ to series expansion for $m=0..2$

    $u^m\cdot y(u)=\sum_{k=0}^{\infty}a_k u^{k+r+m}$

  ◦ Shift index using $k->k-m$

    $u^m\cdot y(u)=\sum_{k=m}^{\infty}a_{k-m}u^{k+r}$

  ◦ Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=1..3$

    $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,u^{k+r-1+m}$

  ◦ Shift index using $k->k+1-m$

    $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,u^{k+r}$

  ◦ Convert $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m=2..4$

    $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)(k+r-1)\,u^{k+r-2+m}$

  ◦ Shift index using $k->k+2-m$

$$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\,u^{k+r}$$

Rewrite ODE with series expansions

$$3a_0(2+r)(1+r)\,u^r + (3a_1(3+r)(2+r) - a_0(2+r)(5+6r))\,u^{1+r} + \left(\sum_{k=2}^{\infty} (3a_k(k+r+2)(k+$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $3(2+r)(1+r) = 0$
- Values of r that satisfy the indicial equation

  $r \in \{-2, -1\}$
- Each term must be 0

  $3a_1(3+r)(2+r) - a_0(2+r)(5+6r) = 0$
- Solve for the dependent coefficient(s)

  $a_1 = \frac{a_0(5+6r)}{3(3+r)}$
- Each term in the series must be 0, giving the recursion relation

  $3(a_k + a_{k-2} - 2a_{k-1})\,k^2 + (6(a_k + a_{k-2} - 2a_{k-1})\,r + 9a_k - 4a_{k-2} - 5a_{k-1})\,k + 3(a_k + a_{k-2} - 2a$
- Shift index using $k- >k+2$

  $3(a_{k+2} + a_k - 2a_{k+1})\,(k+2)^2 + (6(a_{k+2} + a_k - 2a_{k+1})\,r + 9a_{k+2} - 4a_k - 5a_{k+1})\,(k+2) + 3(a_{k+}$
- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{3k^2a_k - 6k^2a_{k+1} + 6kra_k - 12kra_{k+1} + 3r^2a_k - 6r^2a_{k+1} + 8ka_k - 29ka_{k+1} + 8ra_k - 29ra_{k+1} + 5a_k - 33a_{k+1}}{3(k^2+2kr+r^2+7k+7r+12)}$
- Recursion relation for $r = -2$

  $a_{k+2} = -\frac{3k^2a_k - 6k^2a_{k+1} - 4ka_k - 5ka_{k+1} + a_k + a_{k+1}}{3(k^2+3k+2)}$
- Solution for $r = -2$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k-2}, a_{k+2} = -\frac{3k^2a_k - 6k^2a_{k+1} - 4ka_k - 5ka_{k+1} + a_k + a_{k+1}}{3(k^2+3k+2)}, a_1 = -\frac{7a_0}{3}\right]$
- Revert the change of variables $u = x+1$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k(x+1)^{k-2}, a_{k+2} = -\frac{3k^2a_k - 6k^2a_{k+1} - 4ka_k - 5ka_{k+1} + a_k + a_{k+1}}{3(k^2+3k+2)}, a_1 = -\frac{7a_0}{3}\right]$
- Recursion relation for $r = -1$

  $a_{k+2} = -\frac{3k^2a_k - 6k^2a_{k+1} + 2ka_k - 17ka_{k+1} - 10a_{k+1}}{3(k^2+5k+6)}$
- Solution for $r = -1$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k-1}, a_{k+2} = -\frac{3k^2a_k - 6k^2a_{k+1} + 2ka_k - 17ka_{k+1} - 10a_{k+1}}{3(k^2+5k+6)}, a_1 = -\frac{a_0}{6}\right]$
- Revert the change of variables $u = x+1$

2.1.120 Problem 122

Internal problem ID [9292]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 122
Date solved : `Monday, January 27, 2025 at 06:01:04 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$4x^2\left(x^2+2x+3\right)y''-x\left(-15x^2-14x+3\right)y'+\left(7x^2+3\right)y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.171 (sec)

Writing the ode as

$$\left(4x^4+8x^3+12x^2\right)y''+\left(15x^3+14x^2-3x\right)y'+\left(7x^2+3\right)y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=4x^4+8x^3+12x^2\\B&=15x^3+14x^2-3x\\C&=7x^2+3\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned}r&=\frac{s}{t}\\&=\frac{2AB'-2BA'+B^2-4AC}{4A^2}\end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{-7}{64x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned}s&=-7\\t&=64x^2\end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(-\frac{7}{64x^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.224: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 64x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{7}{64x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{7}{64}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{7}{8} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{8} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = -\frac{7}{64x^2}$$

Since the gcd$(s,t) = 1$. This gives $b = -\frac{7}{64}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{8} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{8}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = -\frac{7}{64x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{7}{8}$	$\frac{1}{8}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{7}{8}$	$\frac{1}{8}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{8}$ then

$$
\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\
&= \frac{1}{8} - \left(\frac{1}{8}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\
&= \frac{1}{8x} + (-)(0) \\
&= \frac{1}{8x} \\
&= \frac{1}{8x}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(\frac{1}{8x}\right)(0)+\left(\left(-\frac{1}{8x^2}\right)+\left(\frac{1}{8x}\right)^2-\left(-\frac{7}{64x^2}\right)\right)=0$$
$$0=0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z''=rz$ is

$$\begin{aligned}z_1(x)&=pe^{\int \omega\,dx}\\&=\mathrm{e}^{\int \frac{1}{8x}dx}\\&=x^{1/8}\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}y_1&=z_1e^{\int -\frac{1}{2}\frac{B}{A}\,dx}\\&=z_1e^{-\int \frac{1}{2}\frac{15x^3+14x^2-3x}{4x^4+8x^3+12x^2}\,dx}\\&=z_1e^{\frac{\ln(x)}{8}-\ln(x^2+2x+3)}\\&=z_1\left(\frac{x^{1/8}}{x^2+2x+3}\right)\end{aligned}$$

Which simplifies to

$$y_1=\frac{x^{1/4}}{x^2+2x+3}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2=y_1\int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}y_2&=y_1\int \frac{e^{\int -\frac{15x^3+14x^2-3x}{4x^4+8x^3+12x^2}\,dx}}{(y_1)^2}\,dx\\&=y_1\int \frac{e^{\frac{\ln(x)}{4}-2\ln(x^2+2x+3)}}{(y_1)^2}\,dx\\&=y_1\left(\frac{4\sqrt{x}\,\mathrm{e}^{\frac{\ln(x)}{4}-2\ln(x^2+2x+3)}\,(x^2+2x+3)^2}{3}\right)\end{aligned}$$

Therefore the solution is

$$\begin{aligned}y&=c_1y_1+c_2y_2\\&=c_1\left(\frac{x^{1/4}}{x^2+2x+3}\right)+c_2\left(\frac{x^{1/4}}{x^2+2x+3}\left(\frac{4\sqrt{x}\,\mathrm{e}^{\frac{\ln(x)}{4}-2\ln(x^2+2x+3)}\,(x^2+2x+3)^2}{3}\right)\right)\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$4x^2(x^2+2x+3)\left(\frac{d^2}{dx^2}y(x)\right) - x(-15x^2-14x+3)\left(\frac{d}{dx}y(x)\right) + (7x^2+3)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{(7x^2+3)y(x)}{4x^2(x^2+2x+3)} - \frac{(15x^2+14x-3)\left(\frac{d}{dx}y(x)\right)}{4x(x^2+2x+3)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x) + \frac{(15x^2+14x-3)\left(\frac{d}{dx}y(x)\right)}{4x(x^2+2x+3)} + \frac{(7x^2+3)y(x)}{4x^2(x^2+2x+3)} = 0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

  $\left[P_2(x) = \frac{15x^2+14x-3}{4x(x^2+2x+3)}, P_3(x) = \frac{7x^2+3}{4x^2(x^2+2x+3)}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x=0$

  $(x \cdot P_2(x))\bigg|_{x=0} = -\frac{1}{4}$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x=0$

  $(x^2 \cdot P_3(x))\bigg|_{x=0} = \frac{1}{4}$

  ◦ $x=0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $4x^2(x^2+2x+3)\left(\frac{d^2}{dx^2}y(x)\right) + x(15x^2+14x-3)\left(\frac{d}{dx}y(x)\right) + (7x^2+3)\,y(x) = 0$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $x^m \cdot y(x)$ to series expansion for $m = 0..2$

  $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

  ◦ Shift index using $k- >k-m$

  $x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

  ◦ Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m = 1..3$

  $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$

  ◦ Shift index using $k- >k+1-m$

  $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$

  ◦ Convert $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m = 2..4$

  $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r-2+m}$

  ◦ Shift index using $k- >k+2-m$

  $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$

  Rewrite ODE with series expansions

$$3a_0(-1+4r)(-1+r)x^r + (3a_1(3+4r)r + 2a_0r(3+4r))x^{1+r} + \left(\sum_{k=2}^{\infty} (3a_k(4k+4r-1)(k+r-\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $3(-1+4r)(-1+r) = 0$
- Values of r that satisfy the indicial equation
  $r \in \{1, \frac{1}{4}\}$
- Each term must be 0
  $3a_1(3+4r)r + 2a_0r(3+4r) = 0$
- Solve for the dependent coefficient(s)
  $a_1 = -\frac{2a_0}{3}$
- Each term in the series must be 0, giving the recursion relation
  $(4k+4r-1)(k+r-1)(3a_k + 2a_{k-1} + a_{k-2}) = 0$
- Shift index using $k->k+2$
  $(4k+4r+7)(k+r+1)(3a_{k+2} + 2a_{k+1} + a_k) = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+2} = -\frac{2a_{k+1}}{3} - \frac{a_k}{3}$
- Recursion relation for $r = 1$
  $a_{k+2} = -\frac{2a_{k+1}}{3} - \frac{a_k}{3}$
- Solution for $r = 1$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+1}, a_{k+2} = -\frac{2a_{k+1}}{3} - \frac{a_k}{3}, a_1 = -\frac{2a_0}{3}\right]$
- Recursion relation for $r = \frac{1}{4}$
  $a_{k+2} = -\frac{2a_{k+1}}{3} - \frac{a_k}{3}$
- Solution for $r = \frac{1}{4}$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{4}}, a_{k+2} = -\frac{2a_{k+1}}{3} - \frac{a_k}{3}, a_1 = -\frac{2a_0}{3}\right]$
- Combine solutions and rename parameters
  $\left[y(x) = \left(\sum_{k=0}^{\infty} a_k x^{k+1}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{4}}\right), a_{k+2} = -\frac{2a_{k+1}}{3} - \frac{a_k}{3}, a_1 = -\frac{2a_0}{3}, b_{k+2} = -\frac{2b_{k+1}}{3} - \frac{b_k}{3}, b_1 = -\right.$

CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2(x^2-2x+1)\,y''-x(3+x)\,y'+(4+x)\,y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.301 (sec)

Writing the ode as

$$x^2(x-1)^2\,y''+\left(-x^2-3x\right)y'+(4+x)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2(x-1)^2\\ B &= -x^2-3x\\ C &= 4+x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t}\\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{7x^2+10x-1}{4x^2\left(x-1\right)^4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 7x^2+10x-1\\ t &= 4x^2(x-1)^4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{7x^2+10x-1}{4x^2\left(x-1\right)^4}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.226: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 2 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2(x-1)^4$. There is a pole at $x = 0$ of order 2. There is a pole at $x = 1$ of order 4. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{2}{(x-1)^3} - \frac{3}{2(x-1)} + \frac{4}{(x-1)^4} + \frac{3}{2x} + \frac{7}{4(x-1)^2} - \frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

Looking at higher order poles of order $2v \geq 4$ (must be even order for case one).Then for each pole c, $[\sqrt{r}]_c$ is the sum of terms $\frac{1}{(x-c)^i}$ for $2 \leq i \leq v$ in the Laurent series expansion of $\sqrt{r}$ expanded around each pole c. Hence

$$[\sqrt{r}]_c = \sum_{2}^{v} \frac{a_i}{(x-c)^i} \tag{1B}$$

Let a be the coefficient of the term $\frac{1}{(x-c)^v}$ in the above where v is the pole order divided by 2. Let b be the coefficient of $\frac{1}{(x-c)^{v+1}}$ in r minus the coefficient of $\frac{1}{(x-c)^{v+1}}$ in $[\sqrt{r}]_c$. Then

$$
\begin{aligned}
\alpha_c^+ &= \frac{1}{2}\left(\frac{b}{a}+v\right)\\
\alpha_c^- &= \frac{1}{2}\left(-\frac{b}{a}+v\right)
\end{aligned}
$$

The partial fraction decomposition of r is

$$
r = -\frac{2}{(x-1)^3} - \frac{3}{2(x-1)} + \frac{4}{(x-1)^4} + \frac{3}{2x} + \frac{7}{4(x-1)^2} - \frac{1}{4x^2}
$$

There is pole in r at $x=1$ of order 4, hence $v=2$. Expanding $\sqrt{r}$ as Laurent series about this pole $c=1$ gives

$$
[\sqrt{r}]_c \approx \frac{2}{(x-1)^2} - \frac{1}{2(x-1)} + \frac{21}{32} - \frac{9x}{32} + \frac{53(x-1)^2}{256} - \frac{149(x-1)^3}{1024} + \dots \tag{2B}
$$

Using eq. (1B), taking the sum up to $v=2$ the above becomes

$$
[\sqrt{r}]_c = \frac{2}{(x-1)^2} \tag{3B}
$$

The above shows that the coefficient of $\frac{1}{(x-1)^2}$ is

$$
a = 2
$$

Now we need to find b. let b be the coefficient of the term $\frac{1}{(x-c)^{v+1}}$ in r minus the coefficient of the same term but in the sum $[\sqrt{r}]_c$ found in eq. (3B). Here c is current pole which is $c=1$. This term becomes $\frac{1}{(x-1)^3}$. The coefficient of this term in the sum $[\sqrt{r}]_c$ is seen to be 0 and the coefficient of this term r is found from the partial fraction decomposition from above to be -2. Therefore

$$
\begin{aligned}
b &= (-2) - (0)\\
&= -2
\end{aligned}
$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= \frac{2}{(x-1)^2}\\
\alpha_c^+ &= \frac{1}{2}\left(\frac{b}{a}+v\right) = \frac{1}{2}\left(\frac{-2}{2}+2\right) = \frac{1}{2}\\
\alpha_c^- &= \frac{1}{2}\left(-\frac{b}{a}+v\right) = \frac{1}{2}\left(-\frac{-2}{2}+2\right) = \frac{3}{2}
\end{aligned}
$$

Since the order of r at ∞ is $4>2$ then

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0\\
\alpha_\infty^+ &= 0\\
\alpha_\infty^- &= 1
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{7x^2+10x-1}{4x^2(x-1)^4}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$
1	4	$\frac{2}{(x-1)^2}$	$\frac{1}{2}$	$\frac{3}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^+ + \alpha_{c_2}^+\right) \\ &= 1 - (1) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1}\right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x-c_2}\right) + (-)[\sqrt{r}]_\infty \\ &= \frac{1}{2x} + \frac{2}{(x-1)^2} + \frac{1}{2x-2} + (-)\,(0) \\ &= \frac{1}{2x} + \frac{2}{(x-1)^2} + \frac{1}{2x-2} \\ &= \frac{2x^2+x+1}{2x\,(x-1)^2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{2x} + \frac{2}{(x-1)^2} + \frac{1}{2x-2}\right)(0) + \left(\left(-\frac{1}{2x^2} - \frac{4}{(x-1)^3} - \frac{1}{2\,(x-1)^2}\right) + \left(\frac{1}{2x} + \frac{2}{(x-1)^2} + \frac{1}{2x-\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega\,dx} \\ &= e^{\int \left(\frac{1}{2x} + \frac{2}{(x-1)^2} + \frac{1}{2x-2}\right)dx} \\ &= \sqrt{x}\,\sqrt{x-1}\,e^{-\frac{2}{x-1}} \end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-x^2-3x}{x^2(x-1)^2}\,dx} \\
&= z_1 e^{\frac{3\ln(x)}{2}-\frac{2}{x-1}-\frac{3\ln(x-1)}{2}} \\
&= z_1 \left(\frac{x^{3/2}\mathrm{e}^{-\frac{2}{x-1}}}{(x-1)^{3/2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{x^{3/2}\mathrm{e}^{-\frac{4}{x-1}}\sqrt{x(x-1)}}{(x-1)^{3/2}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-x^2-3x}{x^2(x-1)^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{3\ln(x)-\frac{4}{x-1}-3\ln(x-1)}}{(y_1)^2}\,dx \\
&= y_1 \left(\mathrm{e}^{-4}\,\mathrm{Ei}_1\left(-\frac{4}{x-1}-4\right)\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\

- $x \cdot P_2(x)$ is analytic at $x = 0$

  $(x \cdot P_2(x))\Big|_{x=0} = -3$

- $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $(x^2 \cdot P_3(x))\Big|_{x=0} = 4$

- $x = 0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $x^2(x^2-2x+1)\left(\frac{d^2}{dx^2}y(x)\right) - x(x+3)\left(\frac{d}{dx}y(x)\right) + (x+4)\,y(x) = 0$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $x^m \cdot y(x)$ to series expansion for $m = 0..1$

  $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- Shift index using $k- >k - m$

  $x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m = 1..2$

  $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$

- Shift index using $k- >k + 1 - m$

  $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$

- Convert $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m = 2..4$

  $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r-2+m}$

- Shift index using $k- >k + 2 - m$

  $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(-2+r)^2\,x^r + \left(a_1(-1+r)^2 - a_0(1+2r)\,(-1+r)\right)x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(k+r-2)^2 - a_{k-1}(2k -\right.\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-2+r)^2 = 0$

- Values of r that satisfy the indicial equation

  $r = 2$

- Each term must be 0

  $a_1(-1+r)^2 - a_0(1+2r)\,(-1+r) = 0$

- Solve for the dependent coefficient(s)

  $a_1 = \frac{a_0(1+2r)}{-1+r}$

- Each term in the series must be 0, giving the recursion relation

  $((a_k + a_{k-2} - 2a_{k-1})\,k + (a_k + a_{k-2} - 2a_{k-1})\,r - 2a_k - 3a_{k-2} + a_{k-1})\,(k+r-2) = 0$

- Shift index using $k- >k + 2$

$$((a_{k+2}+a_k-2a_{k+1})(k+2)+(a_{k+2}+a_k-2a_{k+1})r-2a_{k+2}-3a_k+a_{k+1})(k+r)=0$$

- Recursion relation that defines series solution to ODE
$$a_{k+2}=-\frac{ka_k-2ka_{k+1}+ra_k-2ra_{k+1}-a_k-3a_{k+1}}{k+r}$$
- Recursion relation for $r=2$
$$a_{k+2}=-\frac{ka_k-2ka_{k+1}+a_k-7a_{k+1}}{k+2}$$
- Solution for $r=2$
$$\left[y(x)=\sum_{k=0}^{\infty}a_kx^{k+2}, a_{k+2}=-\frac{ka_k-2ka_{k+1}+a_k-7a_{k+1}}{k+2}, a_1=5a_0\right]$$

2.1.122 Problem 124

Internal problem ID [9294]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 124
Date solved : `Monday, January 27, 2025 at 06:01:06 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$2x^2(2+x)\,y''+5x^2y'+(1+x)\,y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.207 (sec)

Writing the ode as

$$\left(2x^3+4x^2\right)y''+5x^2y'+(1+x)\,y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2x^3+4x^2 \\ B &= 5x^2 \\ C &= 1+x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{-3x^2-24x-16}{16\left(x^2+2x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -3x^2-24x-16 \\ t &= 16\left(x^2+2x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{-3x^2-24x-16}{16\left(x^2+2x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.228: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16(x^2 + 2x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -2$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{5}{16\,(2+x)^2} - \frac{1}{8x} - \frac{1}{4x^2} + \frac{1}{16+8x}$$

For the pole at $x = -2$ let b be the coefficient of $\frac{1}{(2+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{5}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{4} \end{aligned}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{-3x^2 - 24x - 16}{16\left(x^2 + 2x\right)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{3}{16}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{4} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{4}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{-3x^2 - 24x - 16}{16\left(x^2 + 2x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
-2	2	0	$\frac{5}{4}$	$-\frac{1}{4}$
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{3}{4}$	$\frac{1}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{4}$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^+\right) \\
&= \frac{1}{4} - \left(\frac{1}{4}\right) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x-c_2} \right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{1}{4\,(2+x)} + \frac{1}{2x} + (-)\,(0) \\
&= -\frac{1}{4\,(2+x)} + \frac{1}{2x} \\
&= \frac{x+4}{4x\,(2+x)}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{4(2+x)} + \frac{1}{2x}\right)(0) + \left(\left(\frac{1}{4(2+x)^2} - \frac{1}{2x^2}\right) + \left(-\frac{1}{4(2+x)} + \frac{1}{2x}\right)^2 - \left(\frac{-3x^2 - 24x - 16}{16(x^2+2x)^2}\right)\right) = 0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega\, dx} \\ &= e^{\int \left(-\frac{1}{4(2+x)} + \frac{1}{2x}\right) dx} \\ &= \frac{\sqrt{x}}{(2+x)^{1/4}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{5x^2}{2x^3+4x^2}\, dx} \\ &= z_1 e^{-\frac{5\ln(2+x)}{4}} \\ &= z_1 \left(\frac{1}{(2+x)^{5/4}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{\sqrt{x}}{(2+x)^{3/2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{5x^2}{2x^3+4x^2}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-\frac{5\ln(2+x)}{2}}}{(y_1)^2}\, dx \\ &= y_1 \left(2\sqrt{2+x} - 2\sqrt{2}\, \operatorname{arctanh}\left(\frac{\sqrt{2+x}\,\sqrt{2}}{2}\right)\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\frac{\sqrt{x}}{(2+x)^{3/2}}\right) + c_2 \left(\frac{\sqrt{x}}{(2+x)^{3/2}} \left(2\sqrt{2+x} - 2\sqrt{2}\, \operatorname{arctanh}\left(\frac{\sqrt{2+x}\,\sqrt{2}}{2}\right)\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$2x^2(x+2)\left(\frac{d^2}{dx^2}y(x)\right)+5x^2\left(\frac{d}{dx}y(x)\right)+(x+1)\,y(x)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

2.1.123 Problem 125

Internal problem ID [9295]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 125
Date solved : `Monday, January 27, 2025 at 06:01:06 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2\left(-x^2+2\right)y''-2x\left(2x^2+1\right)y'+\left(-2x^2+2\right)y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.372 (sec)

Writing the ode as

$$\left(-x^4+2x^2\right)y''+\left(-4x^3-2x\right)y'+\left(-2x^2+2\right)y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=-x^4+2x^2\\B&=-4x^3-2x\\C&=-2x^2+2\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned}r&=\frac{s}{t} \\ &=\frac{2AB'-2BA'+B^2-4AC}{4A^2}\end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{3x^2-1}{\left(x^3-2x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned}s&=3x^2-1\\t&=\left(x^3-2x\right)^2\end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{3x^2-1}{\left(x^3-2x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.230: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 2 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (x^3 - 2x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = \sqrt{2}$ of order 2. There is a pole at $x = -\sqrt{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4x^2} + \frac{5}{16 (x - \sqrt{2})^2} + \frac{5}{16 (x + \sqrt{2})^2} - \frac{3\sqrt{2}}{32 (x - \sqrt{2})} + \frac{3\sqrt{2}}{32 (x + \sqrt{2})}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2} \end{aligned}$$

For the pole at $x = \sqrt{2}$ let b be the coefficient of $\frac{1}{\left(x-\sqrt{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{5}{16}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{4} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{4}
\end{aligned}$$

For the pole at $x = -\sqrt{2}$ let b be the coefficient of $\frac{1}{\left(x+\sqrt{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{5}{16}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{4} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{4}
\end{aligned}$$

Since the order of r at ∞ is $4 > 2$ then

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= 0 \\
\alpha_\infty^- &= 1
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{3x^2 - 1}{\left(x^3 - 2x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$
$\sqrt{2}$	2	0	$\frac{5}{4}$	$-\frac{1}{4}$
$-\sqrt{2}$	2	0	$\frac{5}{4}$	$-\frac{1}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = 0$ then

$$\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^+ + \alpha_{c_2}^- + \alpha_{c_3}^-\right) \\
&= 0 - (0) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{-}}{x-c_2}\right) + \left((-)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^{-}}{x-c_3}\right) + (+)[\sqrt{r}]_{\infty} \\ &= \frac{1}{2x} - \frac{1}{4\left(x-\sqrt{2}\right)} - \frac{1}{4\left(x+\sqrt{2}\right)} + (0) \\ &= \frac{1}{2x} - \frac{1}{4\left(x-\sqrt{2}\right)} - \frac{1}{4\left(x+\sqrt{2}\right)} \\ &= -\frac{1}{x^3-2x}\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{2x} - \frac{1}{4\left(x-\sqrt{2}\right)} - \frac{1}{4\left(x+\sqrt{2}\right)}\right)(0) + \left(\left(-\frac{1}{2x^2} + \frac{1}{4\left(x-\sqrt{2}\right)^2} + \frac{1}{4\left(x+\sqrt{2}\right)^2}\right) + \left(\frac{1}{2x} - \frac{}{4(}\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}z_1(x) &= p e^{\int \omega\, dx} \\ &= \mathrm{e}^{\int \left(\frac{1}{2x} - \frac{1}{4\left(x-\sqrt{2}\right)} - \frac{1}{4\left(x+\sqrt{2}\right)}\right) dx} \\ &= \frac{\sqrt{x}}{\left(x-\sqrt{2}\right)^{1/4}\left(x+\sqrt{2}\right)^{1/4}}\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-4x^3-2x}{-x^4+2x^2}\, dx} \\ &= z_1 e^{-\frac{5\ln\left(x^2-2\right)}{4} + \frac{\ln(x)}{2}} \\ &= z_1\left(\frac{\sqrt{x}}{\left(x^2-2\right)^{5/4}}\right)\end{aligned}$$

Which simplifies to

$$y_1 = \frac{x}{\left(x^2-2\right)^{3/2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-4x^3-2x}{-x^4+2x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{5\ln(x^2-2)}{2}+\ln(x)}}{(y_1)^2}\,dx \\
&= y_1 \left(\sqrt{x^2-2} + \sqrt{2}\,\arctan\left(\frac{\sqrt{2}}{\sqrt{x^2-2}}\right)\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{x}{(x^2-2)^{3/2}}\right) + c_2 \left(\frac{x}{(x^2-2)^{3/2}}\left(\sqrt{x^2-2} + \sqrt{2}\,\arctan\left(\frac{\sqrt{2}}{\sqrt{x^2-2}}\right)\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve
$x^2(-x^2+2)\left(\frac{d^2}{dx^2}y(x)\right) - 2x(2x^2+1)\left(\frac{d}{dx}y(x)\right) + (-2x^2+2)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2
  $\frac{d^2}{dx^2}y(x)$
- Isolate 2nd derivative
  $\frac{d^2}{dx^2}y(x) = -\frac{2(x^2-1)y(x)}{x^2(x^2-2)} - \frac{2(2x^2+1)\left(\frac{d}{dx}y(x)\right)}{x(x^2-2)}$
- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea
  $\frac{d^2}{dx^2}y(x) + \frac{2(2x^2+1)\left(\frac{d}{dx}y(x)\right)}{x(x^2-2)} + \frac{2(x^2-1)y(x)}{x^2(x^2-2)} = 0$

□ Check to see if x_0 is a regular singular point
  - Define functions
    $\left[P_2(x) = \frac{2(2x^2+1)}{x(x^2-2)}, P_3(x) = \frac{2(x^2-1)}{x^2(x^2-2)}\right]$
  - $x \cdot P_2(x)$ is analytic at $x = 0$
    $\left.(x \cdot P_2(x))\right|_{x=0} = -1$
  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$
    $\left.(x^2 \cdot P_3(x))\right|_{x=0} = 1$
  - $x = 0$is a regular singular point
    Check to see if x_0 is a regular singular point
    $x_0 = 0$
- Multiply by denominators
  $x^2(x^2-2)\left(\frac{d^2}{dx^2}y(x)\right) + 2x(2x^2+1)\left(\frac{d}{dx}y(x)\right) + (2x^2-2)\,y(x) = 0$
- Assume series solution for $y(x)$
  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

- Convert $x^m \cdot y(x)$ to series expansion for $m = 0..2$

  $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- Shift index using $k- >k - m$

  $x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m = 1..3$

  $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1+m}$

- Shift index using $k- >k + 1 - m$

  $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$

- Convert $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m = 2..4$

  $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-2+m}$

- Shift index using $k- >k + 2 - m$

  $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, x^{k+r}$

  Rewrite ODE with series expansions

  $-2a_0(-1+r)^2 x^r - 2a_1 r^2 x^{1+r} + \left(\sum_{k=2}^{\infty} \left(-2a_k(k+r-1)^2 + a_{k-2}(k+r)\,(k+r-1)\right) x^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $-2(-1+r)^2 = 0$

- Values of r that satisfy the indicial equation

  $r = 1$

- Each term must be 0

  $-2a_1 r^2 = 0$

- Solve for the dependent coefficient(s)

  $a_1 = 0$

- Each term in the series must be 0, giving the recursion relation

  $-2a_k(k+r-1)^2 + a_{k-2}(k+r)\,(k+r-1) = 0$

- Shift index using $k- >k + 2$

  $-2a_{k+2}(k+r+1)^2 + a_k(k+r+2)\,(k+r+1) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+2} = \frac{a_k(k+r+2)}{2(k+r+1)}$

- Recursion relation for $r = 1$

  $a_{k+2} = \frac{a_k(k+3)}{2(k+2)}$

- Solution for $r = 1$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+1}, a_{k+2} = \frac{a_k(k+3)}{2(k+2)}, a_1 = 0\right]$

2.1.124 Problem 126

Internal problem ID [9296]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 126
Date solved : `Monday, January 27, 2025 at 06:01:07 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' - x(5-x)\,y' + (9-4x)\,y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.428 (sec)

Writing the ode as

$$x^2y'' + \left(x^2-5x\right)y' + (9-4x)\,y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= x^2-5x \\ C &= 9-4x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2+6x-1}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2+6x-1 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2+6x-1}{4x^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.232: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} + \frac{3}{2x} - \frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} + \frac{3}{2x} - \frac{5}{2x^2} + \frac{15}{2x^3} - \frac{115}{4x^4} + \frac{495}{4x^5} - \frac{2285}{4x^6} + \frac{11055}{4x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 + 6x - 1}{4x^2} \\ &= Q + \frac{R}{4x^2} \\ &= \left(\frac{1}{4}\right) + \left(\frac{6x - 1}{4x^2}\right) \\ &= \frac{1}{4} + \frac{6x - 1}{4x^2} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is 6. Dividing this by leading coefficient in t which is 4 gives $\frac{3}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(\frac{3}{2}\right) - (0) \\ &= \frac{3}{2} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{\frac{3}{2}}{\frac{1}{2}} - 0\right) &= \frac{3}{2} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{\frac{3}{2}}{\frac{1}{2}} - 0\right) &= -\frac{3}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2 + 6x - 1}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	$\frac{3}{2}$	$-\frac{3}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{3}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^+ - (\alpha_{c_1}^+) \\
&= \frac{3}{2} - \left(\frac{1}{2}\right) \\
&= 1
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1} \right) + (+)[\sqrt{r}]_\infty \\
&= \frac{1}{2x} + \left(\frac{1}{2}\right) \\
&= \frac{1}{2x} + \frac{1}{2} \\
&= \frac{1+x}{2x}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned}
(0) + 2\left(\frac{1}{2x} + \frac{1}{2}\right)(1) + \left(\left(-\frac{1}{2x^2}\right) + \left(\frac{1}{2x} + \frac{1}{2}\right)^2 - \left(\frac{x^2+6x-1}{4x^2}\right)\right) &= 0 \\
\frac{1-a_0}{x} &= 0
\end{aligned}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 1\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = 1 + x$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= (1+x)\, e^{\int \left(\frac{1}{2x}+\frac{1}{2}\right)dx} \\ &= (1+x)\, e^{\frac{x}{2}+\frac{\ln(x)}{2}} \\ &= (1+x)\sqrt{x}\, e^{\frac{x}{2}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{x^2-5x}{x^2}\, dx} \\ &= z_1 e^{-\frac{x}{2}+\frac{5\ln(x)}{2}} \\ &= z_1 \left(x^{5/2} e^{-\frac{x}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = x^3(1+x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{x^2-5x}{x^2}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-x+5\ln(x)}}{(y_1)^2}\, dx \\ &= y_1 \left(-\operatorname{Ei}_1(x) - \frac{e^{-x}}{-1-x}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(x^3(1+x)\right) + c_2\left(x^3(1+x)\left(-\operatorname{Ei}_1(x) - \frac{e^{-x}}{-1-x}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve
$x^2\left(\frac{d^2}{dx^2}y(x)\right) - x(5-x)\left(\frac{d}{dx}y(x)\right) + (9-4x)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2
  $\frac{d^2}{dx^2}y(x)$
- Isolate 2nd derivative
  $\frac{d^2}{dx^2}y(x) = \frac{(-9+4x)y(x)}{x^2} - \frac{(x-5)\left(\frac{d}{dx}y(x)\right)}{x}$
- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

$\frac{d^2}{dx^2}y(x) + \frac{(x-5)\left(\frac{d}{dx}y(x)\right)}{x} - \frac{(-9+4x)y(x)}{x^2} = 0$

- ☐ Check to see if $x_0 = 0$ is a regular singular point
  - Define functions
    $\left[P_2(x) = \frac{x-5}{x}, P_3(x) = -\frac{-9+4x}{x^2}\right]$
  - $x \cdot P_2(x)$ is analytic at $x = 0$
    $\left(x \cdot P_2(x)\right)\bigg|_{x=0} = -5$
  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$
    $\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = 9$
  - $x = 0$is a regular singular point
    Check to see if $x_0 = 0$ is a regular singular point
    $x_0 = 0$
- Multiply by denominators
  $x^2\left(\frac{d^2}{dx^2}y(x)\right) + x(x-5)\left(\frac{d}{dx}y(x)\right) + (9-4x)\,y(x) = 0$
- Assume series solution for $y(x)$
  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$
- ☐ Rewrite ODE with series expansions
  - Convert $x^m \cdot y(x)$ to series expansion for $m = 0..1$
    $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$
  - Shift index using $k- >k-m$
    $x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$
  - Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m = 1..2$
    $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$
  - Shift index using $k- >k+1-m$
    $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$
  - Convert $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion
    $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\,x^{k+r}$
    Rewrite ODE with series expansions
    $a_0(-3+r)^2 x^r + \left(\sum_{k=1}^{\infty} \left(a_k(k+r-3)^2 + a_{k-1}(k-5+r)\right) x^{k+r}\right) = 0$
- $a_0$cannot be 0 by assumption, giving the indicial equation
  $(-3+r)^2 = 0$
- Values of r that satisfy the indicial equation
  $r = 3$
- Each term in the series must be 0, giving the recursion relation
  $a_k(k+r-3)^2 + a_{k-1}(k-5+r) = 0$
- Shift index using $k- >k+1$
  $a_{k+1}(k-2+r)^2 + a_k(k+r-4) = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+1} = -\frac{a_k(k+r-4)}{(k-2+r)^2}$
- Recursion relation for $r = 3$; series terminates at $k = 1$

$a_{k+1} = -\frac{a_k(k-1)}{(k+1)^2}$

- Apply recursion relation for $k = 0$

  $a_1 = a_0$

- Terminating series solution of the ODE for $r = 3$. Use reduction of order to find the second li

  $y(x) = a_0 \cdot (x + 1)$

2.1.125 Problem 127

Internal problem ID [9297]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 127
Date solved : `Monday, January 27, 2025 at 06:01:08 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$4x^2\left(x^2+x+1\right)y''+12x^2(1+x)\,y'+\left(3x^2+3x+1\right)y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.780 (sec)

Writing the ode as

$$\left(4x^4+4x^3+4x^2\right)y''+\left(12x^3+12x^2\right)y'+\left(3x^2+3x+1\right)y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A&=4x^4+4x^3+4x^2\\ B&=12x^3+12x^2\\ C&=3x^2+3x+1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r&=\frac{s}{t}\\ &=\frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{2x^2-4x-1}{4\left(x^3+x^2+x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s&=2x^2-4x-1\\ t&=4\left(x^3+x^2+x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{2x^2-4x-1}{4\left(x^3+x^2+x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.234: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 2 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^3 + x^2 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -\frac{1}{2} + \frac{i\sqrt{3}}{2}$ of order 2. There is a pole at $x = -\frac{1}{2} - \frac{i\sqrt{3}}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{2x} - \frac{1}{4x^2} + \frac{-\frac{3}{8} - \frac{i\sqrt{3}}{8}}{\left(x + \frac{1}{2} - \frac{i\sqrt{3}}{2}\right)^2} + \frac{-\frac{3}{8} + \frac{i\sqrt{3}}{8}}{\left(x + \frac{1}{2} + \frac{i\sqrt{3}}{2}\right)^2} + \frac{\frac{1}{4} - \frac{5i\sqrt{3}}{12}}{x + \frac{1}{2} - \frac{i\sqrt{3}}{2}} + \frac{\frac{1}{4} + \frac{5i\sqrt{3}}{12}}{x + \frac{1}{2} + \frac{i\sqrt{3}}{2}}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

For the pole at $x = -\frac{1}{2} + \frac{i\sqrt{3}}{2}$ let b be the coefficient of $\frac{1}{\left(x+\frac{1}{2}-\frac{i\sqrt{3}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{8} - \frac{i\sqrt{3}}{8}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} + \frac{\sqrt{-2-2i\sqrt{3}}}{4} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} - \frac{\sqrt{-2-2i\sqrt{3}}}{4}
\end{aligned}$$

For the pole at $x = -\frac{1}{2} - \frac{i\sqrt{3}}{2}$ let b be the coefficient of $\frac{1}{\left(x+\frac{1}{2}+\frac{i\sqrt{3}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{8} + \frac{i\sqrt{3}}{8}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} + \frac{\sqrt{-2+2i\sqrt{3}}}{4} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} - \frac{\sqrt{-2+2i\sqrt{3}}}{4}
\end{aligned}$$

Since the order of r at ∞ is $4 > 2$ then

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= 0 \\
\alpha_\infty^- &= 1
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{2x^2-4x-1}{4\left(x^3+x^2+x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$
$-\frac{1}{2}+\frac{i\sqrt{3}}{2}$	2	0	$\frac{1}{2}+\frac{\sqrt{-2-2i\sqrt{3}}}{4}$	$\frac{1}{2}-\frac{\sqrt{-2-2i\sqrt{3}}}{4}$
$-\frac{1}{2}-\frac{i\sqrt{3}}{2}$	2	0	$\frac{1}{2}+\frac{\sqrt{-2+2i\sqrt{3}}}{4}$	$\frac{1}{2}-\frac{\sqrt{-2+2i\sqrt{3}}}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^+ + \alpha_{c_2}^- + \alpha_{c_3}^-\right) \\
&= 1 - (1) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$
\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x - c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{-}}{x - c_2}\right) + \left((-)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^{-}}{x - c_3}\right) + (-)[\sqrt{r}]_{\infty} \\
&= \frac{1}{2x} + \frac{\frac{1}{2} - \frac{\sqrt{-2-2i\sqrt{3}}}{4}}{x + \frac{1}{2} - \frac{i\sqrt{3}}{2}} + \frac{\frac{1}{2} - \frac{\sqrt{-2+2i\sqrt{3}}}{4}}{x + \frac{1}{2} + \frac{i\sqrt{3}}{2}} + (-)(0) \\
&= \frac{1}{2x} + \frac{\frac{1}{2} - \frac{\sqrt{-2-2i\sqrt{3}}}{4}}{x + \frac{1}{2} - \frac{i\sqrt{3}}{2}} + \frac{\frac{1}{2} - \frac{\sqrt{-2+2i\sqrt{3}}}{4}}{x + \frac{1}{2} + \frac{i\sqrt{3}}{2}} \\
&= \frac{2x^2 + 1}{2x(x^2 + x + 1)}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(0) + 2\left(\frac{1}{2x} + \frac{\frac{1}{2} - \frac{\sqrt{-2-2i\sqrt{3}}}{4}}{x + \frac{1}{2} - \frac{i\sqrt{3}}{2}} + \frac{\frac{1}{2} - \frac{\sqrt{-2+2i\sqrt{3}}}{4}}{x + \frac{1}{2} + \frac{i\sqrt{3}}{2}}\right)(0) + \left(\left(-\frac{1}{2x^2} - \frac{\frac{1}{2} - \frac{\sqrt{-2-2i\sqrt{3}}}{4}}{\left(x + \frac{1}{2} - \frac{i\sqrt{3}}{2}\right)^2} - \frac{\frac{1}{2} - \frac{\sqrt{-2+2i\sqrt{3}}}{4}}{\left(x + \frac{1}{2} + \frac{i\sqrt{3}}{2}\right)^2}\right) -
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(\frac{1}{2x} + \frac{\frac{1}{2} - \frac{\sqrt{-2-2i\sqrt{3}}}{4}}{x + \frac{1}{2} - \frac{i\sqrt{3}}{2}} + \frac{\frac{1}{2} - \frac{\sqrt{-2+2i\sqrt{3}}}{4}}{x + \frac{1}{2} + \frac{i\sqrt{3}}{2}}\right) dx} \\
&= (x^2 + x + 1)^{1/4} \sqrt{x}\,\sqrt{2}\, \mathrm{e}^{-\frac{\sqrt{3}\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}{2}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{12x^3 + 12x^2}{4x^4 + 4x^3 + 4x^2}\, dx} \\
&= z_1 e^{-\frac{3\ln(x^2 + x + 1)}{4} - \frac{\sqrt{3}\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}{2}} \\
&= z_1 \left(\frac{\mathrm{e}^{-\frac{\sqrt{3}\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}{2}}}{(x^2 + x + 1)^{3/4}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{\mathrm{e}^{-\sqrt{3}\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)} \sqrt{x}\,\sqrt{2}}{\sqrt{x^2 + x + 1}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{12x^3+12x^2}{4x^4+4x^3+4x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-\frac{3\ln\left(x^2+x+1\right)}{2}-\sqrt{3}\,\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}}{(y_1)^2}\, dx \\
&= y_1 \left(\int \frac{\mathrm{e}^{-\frac{3\ln\left(x^2+x+1\right)}{2}-\sqrt{3}\,\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}\left(x^2+x+1\right)\mathrm{e}^{2\sqrt{3}\,\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}}{2x} dx\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{\mathrm{e}^{-\sqrt{3}\,\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}\sqrt{x}\,\sqrt{2}}{\sqrt{x^2+x+1}}\right) \\
&\quad + c_2 \left(\frac{\mathrm{e}^{-\sqrt{3}\,\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}\sqrt{x}\,\sqrt{2}}{\sqrt{x^2+x+1}}\left(\int \frac{\mathrm{e}^{-\frac{3\ln\left(x^2+x+1\right)}{2}-\sqrt{3}\,\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}\left(x^2+x+1\right)\mathrm{e}^{2\sqrt{3}\,\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}}{2x} dx\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$4x^2(x^2+x+1)\left(\frac{d^2}{dx^2}y(x)\right)+12x^2(x+1)\left(\frac{d}{dx}y(x)\right)+(3x^2+3x+1)\,y(x)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x)=-\frac{(3x^2+3x+1)y(x)}{4x^2(x^2+x+1)}-\frac{3(x+1)\left(\frac{d}{dx}y(x)\right)}{x^2+x+1}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x)+\frac{3(x+1)\left(\frac{d}{dx}y(x)\right)}{x^2+x+1}+\frac{(3x^2+3x+1)y(x)}{4x^2(x^2+x+1)}=0$

- ☐ Check to see if x_0 is a regular singular point

  - Define functions

    $\left[P_2(x)=\frac{3(x+1)}{x^2+x+1}, P_3(x)=\frac{3x^2+3x+1}{4x^2(x^2+x+1)}\right]$

  - $x\cdot P_2(x)$ is analytic at $x=0$

    $\left.(x\cdot P_2(x))\right|_{x=0}=0$

  - $x^2\cdot P_3(x)$ is analytic at $x=0$

    $\left.(x^2\cdot P_3(x))\right|_{x=0}=\frac{1}{4}$

  - $x=0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=0$

- Multiply by denominators

$$4x^2(x^2+x+1)\left(\frac{d^2}{dx^2}y(x)\right)+12x^2(x+1)\left(\frac{d}{dx}y(x)\right)+(3x^2+3x+1)\,y(x)=0$$

- Assume series solution for $y(x)$

$$y(x)=\sum_{k=0}^{\infty}a_k x^{k+r}$$

- ☐ Rewrite ODE with series expansions
  - Convert $x^m\cdot y(x)$ to series expansion for $m=0..2$

    $$x^m\cdot y(x)=\sum_{k=0}^{\infty}a_k x^{k+r+m}$$
  - Shift index using $k->k-m$

    $$x^m\cdot y(x)=\sum_{k=m}^{\infty}a_{k-m}x^{k+r}$$
  - Convert $x^m\cdot\left(\frac{d}{dx}y(x)\right)$ to series expansion for $m=2..3$

    $$x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,x^{k+r-1+m}$$
  - Shift index using $k->k+1-m$

    $$x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,x^{k+r}$$
  - Convert $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m=2..4$

    $$x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,x^{k+r-2+m}$$
  - Shift index using $k->k+2-m$

    $$x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=-2+m}^{\infty}a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$$

  Rewrite ODE with series expansions

  $$a_0(-1+2r)^2x^r+\left(a_1(1+2r)^2+a_0(3+2r)\,(1+2r)\right)x^{1+r}+\left(\sum_{k=2}^{\infty}\left(a_k(2k+2r-1)^2+a_{k-1}(2k\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $$(-1+2r)^2=0$$
- Values of r that satisfy the indicial equation

  $$r=\frac{1}{2}$$
- Each term must be 0

  $$a_1(1+2r)^2+a_0(3+2r)\,(1+2r)=0$$
- Solve for the dependent coefficient(s)

  $$a_1=-\frac{(3+2r)a_0}{1+2r}$$
- Each term in the series must be 0, giving the recursion relation

  $$4\left((a_k+a_{k-2}+a_{k-1})\,k+(a_k+a_{k-2}+a_{k-1})\,r-\frac{a_k}{2}-\frac{3a_{k-2}}{2}+\frac{a_{k-1}}{2}\right)\left(k+r-\frac{1}{2}\right)=0$$
- Shift index using $k->k+2$

  $$4\left((a_{k+2}+a_k+a_{k+1})\,(k+2)+(a_{k+2}+a_k+a_{k+1})\,r-\frac{a_{k+2}}{2}-\frac{3a_k}{2}+\frac{a_{k+1}}{2}\right)\left(k+\frac{3}{2}+r\right)=0$$
- Recursion relation that defines series solution to ODE

  $$a_{k+2}=-\frac{2ka_k+2ka_{k+1}+2ra_k+2ra_{k+1}+a_k+5a_{k+1}}{2k+2r+3}$$
- Recursion relation for $r=\frac{1}{2}$

  $$a_{k+2}=-\frac{2ka_k+2ka_{k+1}+2a_k+6a_{k+1}}{2k+4}$$
- Solution for $r=\frac{1}{2}$

  $$\left[y(x)=\sum_{k=0}^{\infty}a_k x^{k+\frac{1}{2}},a_{k+2}=-\frac{2ka_k+2ka_{k+1}+2a_k+6a_{k+1}}{2k+4},a_1=-2a_0\right]$$

2.1.126 Problem 128

Internal problem ID [9298]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 128
Date solved : `Monday, January 27, 2025 at 06:01:09 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2\left(x^2+x+1\right)y''-x\left(-2x^2-4x+1\right)y'+y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.926 (sec)

Writing the ode as

$$x^2\left(x^2+x+1\right)y''+\left(2x^3+4x^2-x\right)y'+y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A&=x^2\left(x^2+x+1\right)\\ B&=2x^3+4x^2-x \\ C&=1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r&=\frac{s}{t} \\ &=\frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{10x^2-8x-1}{4\left(x^3+x^2+x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s&=10x^2-8x-1\\ t&=4\left(x^3+x^2+x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{10x^2-8x-1}{4\left(x^3+x^2+x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.236: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 2 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^3 + x^2 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -\frac{1}{2} + \frac{i\sqrt{3}}{2}$ of order 2. There is a pole at $x = -\frac{1}{2} - \frac{i\sqrt{3}}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{-\frac{29}{24} - \frac{7i\sqrt{3}}{24}}{\left(x + \frac{1}{2} - \frac{i\sqrt{3}}{2}\right)^2} + \frac{-\frac{29}{24} + \frac{7i\sqrt{3}}{24}}{\left(x + \frac{1}{2} + \frac{i\sqrt{3}}{2}\right)^2} + \frac{\frac{3}{4} - \frac{41i\sqrt{3}}{36}}{x + \frac{1}{2} - \frac{i\sqrt{3}}{2}} + \frac{\frac{3}{4} + \frac{41i\sqrt{3}}{36}}{x + \frac{1}{2} + \frac{i\sqrt{3}}{2}} - \frac{3}{2x} - \frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

For the pole at $x=-\frac{1}{2}+\frac{i\sqrt{3}}{2}$ let b be the coefficient of $\frac{1}{\left(x+\frac{1}{2}-\frac{i\sqrt{3}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b=-\frac{29}{24}-\frac{7i\sqrt{3}}{24}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^{+} &= \frac{1}{2}+\sqrt{1+4b} = \frac{1}{2}+\frac{\sqrt{-138-42i\sqrt{3}}}{12} \\
\alpha_c^{-} &= \frac{1}{2}-\sqrt{1+4b} = \frac{1}{2}-\frac{\sqrt{-138-42i\sqrt{3}}}{12}
\end{aligned}$$

For the pole at $x=-\frac{1}{2}-\frac{i\sqrt{3}}{2}$ let b be the coefficient of $\frac{1}{\left(x+\frac{1}{2}+\frac{i\sqrt{3}}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b=-\frac{29}{24}+\frac{7i\sqrt{3}}{24}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^{+} &= \frac{1}{2}+\sqrt{1+4b} = \frac{1}{2}+\frac{\sqrt{-138+42i\sqrt{3}}}{12} \\
\alpha_c^{-} &= \frac{1}{2}-\sqrt{1+4b} = \frac{1}{2}-\frac{\sqrt{-138+42i\sqrt{3}}}{12}
\end{aligned}$$

Since the order of r at ∞ is $4>2$ then

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= 0 \\
\alpha_\infty^{-} &= 1
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r=\frac{10x^2-8x-1}{4\left(x^3+x^2+x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$
$-\frac{1}{2}+\frac{i\sqrt{3}}{2}$	2	0	$\frac{1}{2}+\frac{\sqrt{-138-42i\sqrt{3}}}{12}$	$\frac{1}{2}-\frac{\sqrt{-138-42i\sqrt{3}}}{12}$
$-\frac{1}{2}-\frac{i\sqrt{3}}{2}$	2	0	$\frac{1}{2}+\frac{\sqrt{-138+42i\sqrt{3}}}{12}$	$\frac{1}{2}-\frac{\sqrt{-138+42i\sqrt{3}}}{12}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-}=1$ then

$$\begin{aligned}
d &= \alpha_\infty^{-}-\left(\alpha_{c_1}^{+}+\alpha_{c_2}^{-}+\alpha_{c_3}^{-}\right) \\
&= 1-(1) \\
&= 0
\end{aligned}$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$\omega=\sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c+\frac{\alpha_c^{s(c)}}{x-c}\right)+s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$
\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{-}}{x-c_2}\right) + \left((-)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^{-}}{x-c_3}\right) + (-)[\sqrt{r}]_{\infty} \\
&= \frac{1}{2x} + \frac{\frac{1}{2} - \frac{\sqrt{-138-42i\sqrt{3}}}{12}}{x+\frac{1}{2}-\frac{i\sqrt{3}}{2}} + \frac{\frac{1}{2} - \frac{\sqrt{-138+42i\sqrt{3}}}{12}}{x+\frac{1}{2}+\frac{i\sqrt{3}}{2}} + (-)\,(0) \\
&= \frac{1}{2x} + \frac{\frac{1}{2} - \frac{\sqrt{-138-42i\sqrt{3}}}{12}}{x+\frac{1}{2}-\frac{i\sqrt{3}}{2}} + \frac{\frac{1}{2} - \frac{\sqrt{-138+42i\sqrt{3}}}{12}}{x+\frac{1}{2}+\frac{i\sqrt{3}}{2}} \\
&= \frac{2x^2-2x+1}{2x\,(x^2+x+1)}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(0) + 2\left(\frac{1}{2x} + \frac{\frac{1}{2} - \frac{\sqrt{-138-42i\sqrt{3}}}{12}}{x+\frac{1}{2}-\frac{i\sqrt{3}}{2}} + \frac{\frac{1}{2} - \frac{\sqrt{-138+42i\sqrt{3}}}{12}}{x+\frac{1}{2}+\frac{i\sqrt{3}}{2}}\right)(0) + \left(\left(-\frac{1}{2x^2} - \frac{\frac{1}{2} - \frac{\sqrt{-138-42i\sqrt{3}}}{12}}{\left(x+\frac{1}{2}-\frac{i\sqrt{3}}{2}\right)^2} - \frac{\frac{1}{2} - \frac{\sqrt{-138+42i}}{12}}{\left(x+\frac{1}{2}+\frac{i\sqrt{3}}{2}\right.}\right.\right.
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(\frac{1}{2x} + \frac{\frac{1}{2} - \frac{\sqrt{-138-42i\sqrt{3}}}{12}}{x+\frac{1}{2}-\frac{i\sqrt{3}}{2}} + \frac{\frac{1}{2} - \frac{\sqrt{-138+42i\sqrt{3}}}{12}}{x+\frac{1}{2}+\frac{i\sqrt{3}}{2}}\right) dx} \\
&= \sqrt{x}\,\left(x^2+x+1\right)^{1/4} \sqrt{2}\, \mathrm{e}^{-\frac{7\sqrt{3}\,\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}{6}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{2x^3+4x^2-x}{x^2\left(x^2+x+1\right)}\, dx} \\
&= z_1 e^{\frac{\ln(x)}{2} - \frac{3\ln\left(x^2+x+1\right)}{4} - \frac{7\sqrt{3}\,\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}{6}} \\
&= z_1 \left(\frac{\sqrt{x}\,\mathrm{e}^{-\frac{7\sqrt{3}\,\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}{6}}}{\left(x^2+x+1\right)^{3/4}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{x\,\mathrm{e}^{-\frac{7\sqrt{3}\,\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}{3}}\sqrt{2}}{\sqrt{x^2+x+1}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{2x^3+4x^2-x}{x^2(x^2+x+1)}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{\ln(x)-\frac{3\ln(x^2+x+1)}{2}-\frac{7\sqrt{3}\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}{3}}}{(y_1)^2}\,dx \\
&= y_1 \left(\int \frac{e^{\ln(x)-\frac{3\ln(x^2+x+1)}{2}-\frac{7\sqrt{3}\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}{3}}(x^2+x+1)\,e^{\frac{14\sqrt{3}\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}{3}}}{2x^2}\,dx\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{x\,e^{-\frac{7\sqrt{3}\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}{3}}\sqrt{2}}{\sqrt{x^2+x+1}}\right) \\
&\quad + c_2 \left(\frac{x\,e^{-\frac{7\sqrt{3}\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}{3}}\sqrt{2}}{\sqrt{x^2+x+1}}\left(\int \frac{e^{\ln(x)-\frac{3\ln(x^2+x+1)}{2}-\frac{7\sqrt{3}\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}{3}}(x^2+x+1)\,e^{\frac{14\sqrt{3}\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)}{3}}}{2x^2}\,dx\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2(x^2+x+1)\left(\frac{d^2}{dx^2}y(x)\right) - x(-2x^2-4x+1)\left(\frac{d}{dx}y(x)\right) + y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{y(x)}{x^2(x^2+x+1)} - \frac{(2x^2+4x-1)\left(\frac{d}{dx}y(x)\right)}{x(x^2+x+1)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $\frac{d^2}{dx^2}y(x) + \frac{(2x^2+4x-1)\left(\frac{d}{dx}y(x)\right)}{x(x^2+x+1)} + \frac{y(x)}{x^2(x^2+x+1)} = 0$

□ Check to see if x_0 is a regular singular point

  - Define functions

    $\left[P_2(x) = \frac{2x^2+4x-1}{x(x^2+x+1)}, P_3(x) = \frac{1}{x^2(x^2+x+1)}\right]$

  - $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left.(x \cdot P_2(x))\right|_{x=0} = -1$

  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $\left.(x^2 \cdot P_3(x))\right|_{x=0} = 1$

  - $x = 0$is a regular singular point

    Check to see if x_0 is a regular singular point

    $x_0 = 0$

- Multiply by denominators

$$x^2(x^2+x+1)\left(\frac{d^2}{dx^2}y(x)\right)+x(2x^2+4x-1)\left(\frac{d}{dx}y(x)\right)+y(x)=0$$

- Assume series solution for $y(x)$

$$y(x)=\sum_{k=0}^{\infty} a_k x^{k+r}$$

- □ Rewrite ODE with series expansions
  - ◦ Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m = 1..3$

    $$x^m \cdot \left(\frac{d}{dx}y(x)\right)=\sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$$
  - ◦ Shift index using $k->k+1-m$

    $$x^m \cdot \left(\frac{d}{dx}y(x)\right)=\sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$$
  - ◦ Convert $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m = 2..4$

    $$x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r-2+m}$$
  - ◦ Shift index using $k->k+2-m$

    $$x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$$

  Rewrite ODE with series expansions

  $$a_0(-1+r)^2\,x^r+\left(a_1r^2+a_0r(3+r)\right)x^{1+r}+\left(\sum_{k=2}^{\infty}\left(a_k(k+r-1)^2+a_{k-1}(k+r-1)\,(k+2+r)\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $$(-1+r)^2=0$$
- Values of r that satisfy the indicial equation

  $$r=1$$
- Each term must be 0

  $$a_1r^2+a_0r(3+r)=0$$
- Solve for the dependent coefficient(s)

  $$a_1=-\frac{(3+r)a_0}{r}$$
- Each term in the series must be 0, giving the recursion relation

  $$\left((a_k+a_{k-2}+a_{k-1})\,k+(a_k+a_{k-2}+a_{k-1})\,r-a_k-2a_{k-2}+2a_{k-1}\right)(k+r-1)=0$$
- Shift index using $k->k+2$

  $$\left((a_{k+2}+a_k+a_{k+1})\,(k+2)+(a_{k+2}+a_k+a_{k+1})\,r-a_{k+2}-2a_k+2a_{k+1}\right)(k+r+1)=0$$
- Recursion relation that defines series solution to ODE

  $$a_{k+2}=-\frac{ka_k+ka_{k+1}+ra_k+ra_{k+1}+4a_{k+1}}{k+r+1}$$
- Recursion relation for $r=1$

  $$a_{k+2}=-\frac{ka_k+ka_{k+1}+a_k+5a_{k+1}}{k+2}$$
- Solution for $r=1$

  $$\left[y(x)=\sum_{k=0}^{\infty} a_k x^{k+1}, a_{k+2}=-\frac{ka_k+ka_{k+1}+a_k+5a_{k+1}}{k+2}, a_1=-4a_0\right]$$

2.1.127 Problem 129

Internal problem ID [9299]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 129
Date solved : `Monday, January 27, 2025 at 06:01:11 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$9x^2y'' + 3x\left(-2x^2 + 3x + 5\right) y' + \left(-14x^2 + 12x + 1\right) y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.506 (sec)

Writing the ode as

$$9x^2y'' + \left(-6x^3 + 9x^2 + 15x\right) y' + \left(-14x^2 + 12x + 1\right) y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 9x^2 \\ B &= -6x^3 + 9x^2 + 15x \\ C &= -14x^2 + 12x + 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{4x^4 - 12x^3 + 33x^2 - 18x - 9}{36x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 4x^4 - 12x^3 + 33x^2 - 18x - 9 \\ t &= 36x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{4x^4 - 12x^3 + 33x^2 - 18x - 9}{36x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.238: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 4 \\ &= -2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 36x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{x^2}{9} - \frac{x}{3} + \frac{11}{12} - \frac{1}{4x^2} - \frac{1}{2x}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x}{3} - \frac{1}{2} + \frac{1}{x} + \frac{3}{4x^2} - \frac{3}{4x^3} - \frac{27}{8x^4} - \frac{117}{32x^5} + \frac{405}{64x^6} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{3}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= -\frac{1}{2} + \frac{x}{3} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4} - \frac{1}{3}x + \frac{1}{9}x^2$$

This shows that the coefficient of 1 in the above is $\frac{1}{4}$. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{4x^4 - 12x^3 + 33x^2 - 18x - 9}{36x^2} \\ &= Q + \frac{R}{36x^2} \\ &= \left(\frac{1}{9}x^2 - \frac{1}{3}x + \frac{11}{12}\right) + \left(\frac{-18x - 9}{36x^2}\right) \\ &= \frac{x^2}{9} - \frac{x}{3} + \frac{11}{12} + \frac{-18x - 9}{36x^2} \end{aligned}$$

We see that the coefficient of the term x in the quotient is $\frac{11}{12}$. Now b can be found.

$$\begin{aligned} b &= \left(\frac{11}{12}\right) - \left(\frac{1}{4}\right) \\ &= \frac{2}{3} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= -\frac{1}{2} + \frac{x}{3} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{\frac{2}{3}}{\frac{1}{3}} - 1\right) &&= \frac{1}{2} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{\frac{2}{3}}{\frac{1}{3}} - 1\right) &&= -\frac{3}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{4x^4 - 12x^3 + 33x^2 - 18x - 9}{36x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-2	$-\frac{1}{2}+\frac{x}{3}$	$\frac{1}{2}$	$-\frac{3}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^+ - (\alpha_{c_1}^+) \\ &= \frac{1}{2} - \left(\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1} \right) + (+)[\sqrt{r}]_\infty \\ &= \frac{1}{2x} + \left(-\frac{1}{2} + \frac{x}{3}\right) \\ &= \frac{1}{2x} - \frac{1}{2} + \frac{x}{3} \\ &= \frac{1}{2x} - \frac{1}{2} + \frac{x}{3} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{2x} - \frac{1}{2} + \frac{x}{3}\right)(0) + \left(\left(-\frac{1}{2x^2} + \frac{1}{3}\right) + \left(\frac{1}{2x} - \frac{1}{2} + \frac{x}{3}\right)^2 - \left(\frac{4x^4 - 12x^3 + 33x^2 - 18x - 9}{36x^2}\right)\right) = 0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega\, dx} \\ &= e^{\int \left(\frac{1}{2x} - \frac{1}{2} + \frac{x}{3}\right) dx} \\ &= \sqrt{x}\, e^{\frac{x(x-3)}{6}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-6x^3+9x^2+15x}{9x^2}\, dx} \\
&= z_1 e^{\frac{x^2}{6}-\frac{x}{2}-\frac{5\ln(x)}{6}} \\
&= z_1\left(\frac{e^{\frac{x(x-3)}{6}}}{x^{5/6}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{e^{\frac{x(x-3)}{3}}}{x^{1/3}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-6x^3+9x^2+15x}{9x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{\frac{x^2}{3}-x-\frac{5\ln(x)}{3}}}{(y_1)^2}\, dx \\
&= y_1\left(\int e^{\frac{x^2}{3}-x-\frac{5\ln(x)}{3}} x^{2/3} e^{-\frac{2x(x-3)}{3}}\, dx\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{e^{\frac{x(x-3)}{3}}}{x^{1/3}}\right) + c_2\left(\frac{e^{\frac{x(x-3)}{3}}}{x^{1/3}}\left(\int e^{\frac{x^2}{3}-x-\frac{5\ln(x)}{3}} x^{2/3} e^{-\frac{2x(x-3)}{3}}\, dx\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$9x^2\left(\frac{d^2}{dx^2}y(x)\right) + 3x(-2x^2+3x+5)\left(\frac{d}{dx}y(x)\right) + (-14x^2+12x+1)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = \frac{(14x^2-12x-1)y(x)}{9x^2} + \frac{(2x^2-3x-5)\left(\frac{d}{dx}y(x)\right)}{3x}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x) - \frac{(2x^2-3x-5)\left(\frac{d}{dx}y(x)\right)}{3x} - \frac{(14x^2-12x-1)y(x)}{9x^2} = 0$

☐ Check to see if $x_0 = 0$ is a regular singular point

  ○ Define functions

$\left[P_2(x) = -\frac{2x^2-3x-5}{3x}, P_3(x) = -\frac{14x^2-12x-1}{9x^2}\right]$

- ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

  $\left(x \cdot P_2(x)\right)\Big|_{x=0} = \frac{5}{3}$

2.1.128 Problem 130

Internal problem ID [9300]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 130
Date solved : `Monday, January 27, 2025 at 06:01:11 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2(1+2x)\,y''+x\left(3x^2+14x+5\right)y'+\left(12x^2+18x+4\right)y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.617 (sec)

Writing the ode as

$$\left(2x^3+x^2\right)y''+\left(3x^3+14x^2+5x\right)y'+\left(12x^2+18x+4\right)y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A&=2x^3+x^2\\ B&=3x^3+14x^2+5x\\ C&=12x^2+18x+4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r&=\frac{s}{t} \\ &=\frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{9x^4-12x^3-16x^2-4x-1}{4\left(2x^2+x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s&=9x^4-12x^3-16x^2-4x-1\\ t&=4\left(2x^2+x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{9x^4-12x^3-16x^2-4x-1}{4\left(2x^2+x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.240: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 4 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(2x^2 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -\frac{1}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{9}{16} - \frac{15}{64\left(x + \frac{1}{2}\right)^2} - \frac{21}{16\left(x + \frac{1}{2}\right)} - \frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2} \end{aligned}$$

For the pole at $x = -\frac{1}{2}$ let b be the coefficient of $\frac{1}{\left(x + \frac{1}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{15}{64}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{5}{8} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{3}{8} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\
&= \sum_{i=0}^{0} a_i x^i \qquad (8)
\end{aligned}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{3}{4} - \frac{7}{8x} - \frac{19}{48x^2} - \frac{151}{288x^3} - \frac{139}{192x^4} - \frac{11383}{10368x^5} - \frac{38729}{20736x^6} - \frac{1212655}{373248x^7} + \dots \qquad (9)$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{3}{4}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\
&= \frac{3}{4} \qquad (10)
\end{aligned}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{9}{16}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{9x^4 - 12x^3 - 16x^2 - 4x - 1}{16x^4 + 16x^3 + 4x^2} \\
&= Q + \frac{R}{16x^4 + 16x^3 + 4x^2} \\
&= \left(\frac{9}{16}\right) + \left(\frac{-21x^3 - \frac{73}{4}x^2 - 4x - 1}{16x^4 + 16x^3 + 4x^2}\right) \\
&= \frac{9}{16} + \frac{-21x^3 - \frac{73}{4}x^2 - 4x - 1}{16x^4 + 16x^3 + 4x^2}
\end{aligned}$$

Since the degree of t is 4, then we see that the coefficient of the term x^3 in the remainder R is -21. Dividing this by leading coefficient in t which is 16 gives $-\frac{21}{16}$. Now b can be found.

$$\begin{aligned}
b &= \left(-\frac{21}{16}\right) - (0) \\
&= -\frac{21}{16}
\end{aligned}$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \frac{3}{4} \\
\alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-\frac{21}{16}}{\frac{3}{4}} - 0\right) &= -\frac{7}{8} \\
\alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-\frac{21}{16}}{\frac{3}{4}} - 0\right) &= \frac{7}{8}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{9x^4 - 12x^3 - 16x^2 - 4x - 1}{4\left(2x^2 + x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$
$-\frac{1}{2}$	2	0	$\frac{5}{8}$	$\frac{3}{8}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
0	$\frac{3}{4}$	$-\frac{7}{8}$	$\frac{7}{8}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = \frac{7}{8}$ then

$$
\begin{aligned}
d &= \alpha_\infty^{-} - \left(\alpha_{c_1}^{+} + \alpha_{c_2}^{-}\right) \\
&= \frac{7}{8} - \left(\frac{7}{8}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c \in \Gamma} \left(s(c) [\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty) [\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((+) [\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x - c_1} \right) + \left((-) [\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{-}}{x - c_2} \right) + (-) [\sqrt{r}]_\infty \\
&= \frac{1}{2x} + \frac{3}{8\left(x + \frac{1}{2}\right)} + (-)\left(\frac{3}{4}\right) \\
&= \frac{1}{2x} + \frac{3}{8\left(x + \frac{1}{2}\right)} - \frac{3}{4} \\
&= \frac{-3x^2 + 2x + 1}{4x^2 + 2x}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(\frac{1}{2x}+\frac{3}{8\left(x+\frac{1}{2}\right)}-\frac{3}{4}\right)(0)+\left(\left(-\frac{1}{2x^2}-\frac{3}{8\left(x+\frac{1}{2}\right)^2}\right)+\left(\frac{1}{2x}+\frac{3}{8\left(x+\frac{1}{2}\right)}-\frac{3}{4}\right)^2-\left(\frac{9x^4-12x^3 -}{4(2x}\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z''=rz$ is

$$\begin{aligned}z_1(x)&=pe^{\int\omega\,dx}\\&=\mathrm{e}^{\int\left(\frac{1}{2x}+\frac{3}{8\left(x+\frac{1}{2}\right)}-\frac{3}{4}\right)dx}\\&=(1+2x)^{3/8}\sqrt{x}\,\mathrm{e}^{-\frac{3x}{4}}\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}y_1&=z_1e^{\int-\frac{1}{2}\frac{B}{A}\,dx}\\&=z_1e^{-\int\frac{1}{2}\frac{3x^3+14x^2+5x}{2x^3+x^2}\,dx}\\&=z_1e^{-\frac{3x}{4}-\frac{5\ln(1+2x)}{8}-\frac{5\ln(x)}{2}}\\&=z_1\left(\frac{\mathrm{e}^{-\frac{3x}{4}}}{(1+2x)^{5/8}x^{5/2}}\right)\end{aligned}$$

Which simplifies to

$$y_1=\frac{\mathrm{e}^{-\frac{3x}{2}}}{(1+2x)^{1/4}x^2}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2=y_1\int\frac{e^{\int-\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}y_2&=y_1\int\frac{e^{\int-\frac{3x^3+14x^2+5x}{2x^3+x^2}\,dx}}{(y_1)^2}\,dx\\&=y_1\int\frac{e^{-\frac{3x}{2}-\frac{5\ln(1+2x)}{4}-5\ln(x)}}{(y_1)^2}\,dx\\&=y_1\left(\int\mathrm{e}^{-\frac{3x}{2}-\frac{5\ln(1+2x)}{4}-5\ln(x)}\sqrt{1+2x}\,x^4\mathrm{e}^{3x}dx\right)\end{aligned}$$

Therefore the solution is

$$\begin{aligned}y&=c_1y_1+c_2y_2\\&=c_1\left(\frac{\mathrm{e}^{-\frac{3x}{2}}}{(1+2x)^{1/4}x^2}\right)+c_2\left(\frac{\mathrm{e}^{-\frac{3x}{2}}}{(1+2x)^{1/4}x^2}\left(\int\mathrm{e}^{-\frac{3x}{2}-\frac{5\ln(1+2x)}{4}-5\ln(x)}\sqrt{1+2x}\,x^4\mathrm{e}^{3x}dx\right)\right)\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2(2x+1)\left(\frac{d^2}{dx^2}y(x)\right)+x(3x^2+14x+5)\left(\frac{d}{dx}y(x)\right)+(12x^2+18x+4)\,y(x)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x)=-\frac{2(6x^2+9x+2)y(x)}{x^2(2x+1)}-\frac{(3x^2+14x+5)\left(\frac{d}{dx}y(x)\right)}{x(2x+1)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x)+\frac{(3x^2+14x+5)\left(\frac{d}{dx}y(x)\right)}{x(2x+1)}+\frac{2(6x^2+9x+2)y(x)}{x^2(2x+1)}=0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

  $\left[P_2(x)=\frac{3x^2+14x+5}{x(2x+1)},P_3(x)=\frac{2(6x^2+9x+2)}{x^2(2x+1)}\right]$

  ◦ $x\cdot P_2(x)$ is analytic at $x=0$

  $(x\cdot P_2(x))\bigg|_{x=0}=5$

  ◦ $x^2\cdot P_3(x)$ is analytic at $x=0$

  $(x^2\cdot P_3(x))\bigg|_{x=0}=4$

  ◦ $x=0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=0$

- Multiply by denominators

  $x^2(2x+1)\left(\frac{d^2}{dx^2}y(x)\right)+x(3x^2+14x+5)\left(\frac{d}{dx}y(x)\right)+(12x^2+18x+4)\,y(x)=0$

- Assume series solution for $y(x)$

  $y(x)=\sum_{k=0}^{\infty}a_kx^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $x^m\cdot y(x)$ to series expansion for $m=0..2$

  $x^m\cdot y(x)=\sum_{k=0}^{\infty}a_kx^{k+r+m}$

  ◦ Shift index using $k->k-m$

  $x^m\cdot y(x)=\sum_{k=m}^{\infty}a_{k-m}x^{k+r}$

  ◦ Convert $x^m\cdot\left(\frac{d}{dx}y(x)\right)$ to series expansion for $m=1..3$

  $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,x^{k+r-1+m}$

  ◦ Shift index using $k->k+1-m$

  $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,x^{k+r}$

  ◦ Convert $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m=2..3$

  $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,x^{k+r-2+m}$

  ◦ Shift index using $k->k+2-m$

  $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=-2+m}^{\infty}a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$

  Rewrite ODE with series expansions

$$a_0(2+r)^2 x^r + \left(a_1(3+r)^2 + 2a_0(3+r)^2\right) x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(k+r+2)^2 + 2a_{k-1}(k+r+2)^2 + 3a_{k-2}\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $(2+r)^2 = 0$
- Values of r that satisfy the indicial equation
  $r = -2$
- Each term must be 0
  $a_1(3+r)^2 + 2a_0(3+r)^2 = 0$
- Solve for the dependent coefficient(s)
  $a_1 = -2a_0$
- Each term in the series must be 0, giving the recursion relation
  $((2k+2r+4)\, a_{k-1} + a_k(k+r+2) + 3a_{k-2})\,(k+r+2) = 0$
- Shift index using $k- >k+2$
  $((2k+8+2r)\, a_{k+1} + a_{k+2}(k+r+4) + 3a_k)\,(k+r+4) = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+2} = -\frac{2ka_{k+1}+2ra_{k+1}+3a_k+8a_{k+1}}{k+r+4}$
- Recursion relation for $r = -2$
  $a_{k+2} = -\frac{2ka_{k+1}+3a_k+4a_{k+1}}{k+2}$
- Solution for $r = -2$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k-2}, a_{k+2} = -\frac{2ka_{k+1}+3a_k+4a_{k+1}}{k+2}, a_1 = -2a_0\right]$

$$16x^2y'' + 4x\left(2x^2 + x + 6\right) y' + \left(18x^2 + 5x + 1\right) y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.469 (sec)

Writing the ode as

$$16x^2y'' + \left(8x^3 + 4x^2 + 24x\right) y' + \left(18x^2 + 5x + 1\right) y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 16x^2 \\ B &= 8x^3 + 4x^2 + 24x \\ C &= 18x^2 + 5x + 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{4x^4 + 4x^3 - 31x^2 - 8x - 16}{64x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 4x^4 + 4x^3 - 31x^2 - 8x - 16 \\ t &= 64x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{4x^4 + 4x^3 - 31x^2 - 8x - 16}{64x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.242: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 4 \\ &= -2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 64x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{x^2}{16} + \frac{x}{16} - \frac{31}{64} - \frac{1}{4x^2} - \frac{1}{8x}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x}{4} + \frac{1}{8} - \frac{1}{x} + \frac{1}{4x^2} - \frac{21}{8x^3} + \frac{37}{16x^4} - \frac{377}{32x^5} + \frac{1137}{64x^6} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{4}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= \frac{1}{8} + \frac{x}{4}\end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{64} + \frac{1}{16}x + \frac{1}{16}x^2$$

This shows that the coefficient of 1 in the above is $\frac{1}{64}$. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{4x^4 + 4x^3 - 31x^2 - 8x - 16}{64x^2} \\ &= Q + \frac{R}{64x^2} \\ &= \left(\frac{1}{16}x^2 + \frac{1}{16}x - \frac{31}{64}\right) + \left(\frac{-8x - 16}{64x^2}\right) \\ &= \frac{x^2}{16} + \frac{x}{16} - \frac{31}{64} + \frac{-8x - 16}{64x^2} \end{aligned}$$

We see that the coefficient of the term x in the quotient is $-\frac{31}{64}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{31}{64}\right) - \left(\frac{1}{64}\right) \\ &= -\frac{1}{2} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{8} + \frac{x}{4} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-\frac{1}{2}}{\frac{1}{4}} - 1\right) &= -\frac{3}{2} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-\frac{1}{2}}{\frac{1}{4}} - 1\right) &= \frac{1}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{4x^4 + 4x^3 - 31x^2 - 8x - 16}{64x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-2	$\frac{1}{8}+\frac{x}{4}$	$-\frac{3}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^+\right) \\
&= \frac{1}{2} - \left(\frac{1}{2}\right) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\
&= \frac{1}{2x} + (-)\left(\frac{1}{8} + \frac{x}{4}\right) \\
&= \frac{1}{2x} - \frac{1}{8} - \frac{x}{4} \\
&= \frac{1}{2x} - \frac{1}{8} - \frac{x}{4}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{gathered}
(0) + 2\left(\frac{1}{2x} - \frac{1}{8} - \frac{x}{4}\right)(0) + \left(\left(-\frac{1}{2x^2} - \frac{1}{4}\right) + \left(\frac{1}{2x} - \frac{1}{8} - \frac{x}{4}\right)^2 - \left(\frac{4x^4 + 4x^3 - 31x^2 - 8x - 16}{64x^2}\right)\right) = 0 \\
0 = 0
\end{gathered}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= e^{\int \left(\frac{1}{2x} - \frac{1}{8} - \frac{x}{4}\right) dx} \\
&= \sqrt{x}\, e^{-\frac{x(x+1)}{8}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{8x^3+4x^2+24x}{16x^2}\,dx} \\
&= z_1 e^{-\frac{x^2}{8}-\frac{x}{8}-\frac{3\ln(x)}{4}} \\
&= z_1\left(\frac{\mathrm{e}^{-\frac{x(x+1)}{8}}}{x^{3/4}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{\mathrm{e}^{-\frac{x(x+1)}{4}}}{x^{1/4}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{8x^3+4x^2+24x}{16x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{x^2}{4}-\frac{x}{4}-\frac{3\ln(x)}{2}}}{(y_1)^2}\,dx \\
&= y_1\left(\int \mathrm{e}^{-\frac{x^2}{4}-\frac{x}{4}-\frac{3\ln(x)}{2}}\sqrt{x}\,\mathrm{e}^{\frac{x(x+1)}{2}}\,dx\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{\mathrm{e}^{-\frac{x(x+1)}{4}}}{x^{1/4}}\right) + c_2\left(\frac{\mathrm{e}^{-\frac{x(x+1)}{4}}}{x^{1/4}}\left(\int \mathrm{e}^{-\frac{x^2}{4}-\frac{x}{4}-\frac{3\ln(x)}{2}}\sqrt{x}\,\mathrm{e}^{\frac{x(x+1)}{2}}\,dx\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$16x^2\left(\frac{d^2}{dx^2}y(x)\right) + 4x(2x^2+x+6)\left(\frac{d}{dx}y(x)\right) + (18x^2+5x+1)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{(18x^2+5x+1)y(x)}{16x^2} - \frac{(2x^2+x+6)\left(\frac{d}{dx}y(x)\right)}{4x}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x) + \frac{(2x^2+x+6)\left(\frac{d}{dx}y(x)\right)}{4x} + \frac{(18x^2+5x+1)y(x)}{16x^2} = 0$

☐ Check to see if $x_0 = 0$ is a regular singular point

  ○ Define functions

$\left[P_2(x) = \frac{2x^2+x+6}{4x}, P_3(x) = \frac{18x^2+5x+1}{16x^2}\right]$

- ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

  $(x \cdot P_2(x))\bigg|_{x=0} = \frac{3}{2}$

- ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $(x^2 \cdot P_3(x))\bigg|_{x=0} = \frac{1}{16}$

- ◦ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $16x^2\left(\frac{d^2}{dx^2}y(x)\right) + 4x(2x^2 + x + 6)\left(\frac{d}{dx}y(x)\right) + (18x^2 + 5x + 1)\,y(x) = 0$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

- □ Rewrite ODE with series expansions

  - ◦ Convert $x^m \cdot y(x)$ to series expansion for $m = 0..2$

    $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

  - ◦ Shift index using $k->k-m$

    $x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

  - ◦ Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m = 1..3$

    $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$

  - ◦ Shift index using $k->k+1-m$

    $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$

  - ◦ Convert $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

    $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(1+4r)^2\,x^r + \left(a_1(5+4r)^2 + a_0(5+4r)\right)x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(4k+4r+1)^2 + a_{k-1}(4k+4r+1)\right.\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(1+4r)^2 = 0$

- Values of r that satisfy the indicial equation

  $r = -\frac{1}{4}$

- Each term must be 0

  $a_1(5+4r)^2 + a_0(5+4r) = 0$

- Solve for the dependent coefficient(s)

  $a_1 = -\frac{a_0}{5+4r}$

- Each term in the series must be 0, giving the recursion relation

  $a_k(4k+4r+1)^2 + (4k+4r+1)\,(2a_{k-2} + a_{k-1}) = 0$

- Shift index using $k->k+2$

  $a_{k+2}(4k+4r+9)^2 + (4k+4r+9)\,(2a_k + a_{k+1}) = 0$

- Recursion relation that defines series solution to ODE

$a_{k+2} = -\frac{2a_k + a_{k+1}}{4k+4r+9}$

- Recursion relation for $r = -\frac{1}{4}$

$a_{k+2} = -\frac{2a_k + a_{k+1}}{4k+8}$

- Solution for $r = -\frac{1}{4}$

$\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k-\frac{1}{4}}, a_{k+2} = -\frac{2a_k + a_{k+1}}{4k+8}, a_1 = -\frac{a_0}{4}\right]$

Solve

$$9x^2(1+x)\,y''+3x\left(-x^2+11x+5\right)y'+\left(-7x^2+16x+1\right)y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.346 (sec)

Writing the ode as

$$\left(9x^3+9x^2\right)y''+\left(-3x^3+33x^2+15x\right)y'+\left(-7x^2+16x+1\right)y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 9x^3+9x^2\\ B &= -3x^3+33x^2+15x\\ C &= -7x^2+16x+1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t}\\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{x^4+6x^3+3x^2-18x-9}{36\left(x^2+x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^4+6x^3+3x^2-18x-9\\ t &= 36\left(x^2+x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{x^4+6x^3+3x^2-18x-9}{36\left(x^2+x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.244: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 4 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 36(x^2 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{36} + \frac{1}{9 + 9x} + \frac{7}{36\,(1 + x)^2} - \frac{1}{4x^2}$$

For the pole at $x = -1$ let b be the coefficient of $\frac{1}{(1+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{7}{36}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{7}{6} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{1}{6} \end{aligned}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{6} + \frac{1}{3x} - \frac{5}{6x^2} + \frac{5}{6x^3} - \frac{7}{3x^4} + \frac{41}{6x^5} - \frac{149}{6x^6} + \frac{277}{3x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{6}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{6} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{36}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^4 + 6x^3 + 3x^2 - 18x - 9}{36x^4 + 72x^3 + 36x^2} \\ &= Q + \frac{R}{36x^4 + 72x^3 + 36x^2} \\ &= \left(\frac{1}{36}\right) + \left(\frac{4x^3 + 2x^2 - 18x - 9}{36x^4 + 72x^3 + 36x^2}\right) \\ &= \frac{1}{36} + \frac{4x^3 + 2x^2 - 18x - 9}{36x^4 + 72x^3 + 36x^2} \end{aligned}$$

Since the degree of t is 4, then we see that the coefficient of the term x^3 in the remainder R is 4. Dividing this by leading coefficient in t which is 36 gives $\frac{1}{9}$. Now b can be found.

$$\begin{aligned} b &= \left(\frac{1}{9}\right) - (0) \\ &= \frac{1}{9} \end{aligned}$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \frac{1}{6} \\
\alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{\frac{1}{9}}{\frac{1}{6}} - 0\right) &= \frac{1}{3} \\
\alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) = \frac{1}{2}\left(-\frac{\frac{1}{9}}{\frac{1}{6}} - 0\right) = -\frac{1}{3}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{x^4 + 6x^3 + 3x^2 - 18x - 9}{36\,(x^2 + x)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
-1	2	0	$\frac{7}{6}$	$-\frac{1}{6}$
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{6}$	$\frac{1}{3}$	$-\frac{1}{3}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{1}{3}$ then

$$
\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^- + \alpha_{c_2}^+\right) \\
&= \frac{1}{3} - \left(\frac{1}{3}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

Substituting the above values in the above results in

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x - c_1} \right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x - c_2} \right) + (+)[\sqrt{r}]_\infty \\
&= -\frac{1}{6\,(1 + x)} + \frac{1}{2x} + \left(\frac{1}{6}\right) \\
&= -\frac{1}{6\,(1 + x)} + \frac{1}{2x} + \frac{1}{6} \\
&= -\frac{1}{6 + 6x} + \frac{1}{2x} + \frac{1}{6}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(-\frac{1}{6\left(1+x\right)}+\frac{1}{2x}+\frac{1}{6}\right)(0)+\left(\left(\frac{1}{6\left(1+x\right)^{2}}-\frac{1}{2x^{2}}\right)+\left(-\frac{1}{6\left(1+x\right)}+\frac{1}{2x}+\frac{1}{6}\right)^{2}-\left(\frac{x^{4}+6x^{3}+3x}{36\left(x^{2}\right.}\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z''=rz$ is

$$\begin{aligned}
z_1(x) &= pe^{\int \omega \,dx}\\
&= \mathrm{e}^{\int \left(-\frac{1}{6(1+x)}+\frac{1}{2x}+\frac{1}{6}\right)dx}\\
&= \frac{\sqrt{x}\,\mathrm{e}^{\frac{x}{6}}}{\left(1+x\right)^{1/6}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}\\
&= z_1 e^{-\int \frac{1}{2}\frac{-3x^3+33x^2+15x}{9x^3+9x^2}\,dx}\\
&= z_1 e^{\frac{x}{6}-\frac{5\ln(x)}{6}-\frac{7\ln(1+x)}{6}}\\
&= z_1\left(\frac{\mathrm{e}^{\frac{x}{6}}}{x^{5/6}\left(1+x\right)^{7/6}}\right)
\end{aligned}$$

Which simplifies to

$$y_1=\frac{\mathrm{e}^{\frac{x}{3}}}{x^{1/3}\left(1+x\right)^{4/3}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2=y_1\int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1\int \frac{e^{\int -\frac{-3x^3+33x^2+15x}{9x^3+9x^2}\,dx}}{\left(y_1\right)^2}\,dx\\
&= y_1\int \frac{e^{\frac{x}{3}-\frac{5\ln(x)}{3}-\frac{7\ln(1+x)}{3}}}{\left(y_1\right)^2}\,dx\\
&= y_1\left(\int \mathrm{e}^{\frac{x}{3}-\frac{5\ln(x)}{3}-\frac{7\ln(1+x)}{3}}x^{2/3}\left(1+x\right)^{8/3}\mathrm{e}^{-\frac{2x}{3}}\,dx\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1y_1+c_2y_2\\
&= c_1\left(\frac{\mathrm{e}^{\frac{x}{3}}}{x^{1/3}\left(1+x\right)^{4/3}}\right)+c_2\left(\frac{\mathrm{e}^{\frac{x}{3}}}{x^{1/3}\left(1+x\right)^{4/3}}\left(\int \mathrm{e}^{\frac{x}{3}-\frac{5\ln(x)}{3}-\frac{7\ln(1+x)}{3}}x^{2/3}\left(1+x\right)^{8/3}\mathrm{e}^{-\frac{2x}{3}}\,dx\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$9x^2(x+1)\left(\frac{d^2}{dx^2}y(x)\right)+3x(-x^2+11x+5)\left(\frac{d}{dx}y(x)\right)+(-7x^2+16x+1)\,y(x)=0$

- Highest derivative means the order of the ODE is 2

$\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

$\frac{d^2}{dx^2}y(x)=\frac{(7x^2-16x-1)y(x)}{9x^2(x+1)}+\frac{(x^2-11x-5)\left(\frac{d}{dx}y(x)\right)}{3x(x+1)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

$\frac{d^2}{dx^2}y(x)-\frac{(x^2-11x-5)\left(\frac{d}{dx}y(x)\right)}{3x(x+1)}-\frac{(7x^2-16x-1)y(x)}{9x^2(x+1)}=0$

☐ Check to see if x_0 is a regular singular point

- ○ Define functions

$\left[P_2(x)=-\frac{x^2-11x-5}{3x(x+1)},P_3(x)=-\frac{7x^2-16x-1}{9x^2(x+1)}\right]$

- ○ $(x+1)\cdot P_2(x)$ is analytic at $x=-1$

$\left((x+1)\cdot P_2(x)\right)\Big|_{x=-1}=\frac{7}{3}$

- ○ $(x+1)^2\cdot P_3(x)$ is analytic at $x=-1$

$\left((x+1)^2\cdot P_3(x)\right)\Big|_{x=-1}=0$

- ○ $x=-1$is a regular singular point

Check to see if x_0 is a regular singular point

$x_0=-1$

- Multiply by denominators

$9x^2(x+1)\left(\frac{d^2}{dx^2}y(x)\right)-3(x^2-11x-5)\,x\left(\frac{d}{dx}y(x)\right)+(-7x^2+16x+1)\,y(x)=0$

- Change variables using $x=u-1$ so that the regular singular point is at $u=0$

$(9u^3-18u^2+9u)\left(\frac{d^2}{du^2}y(u)\right)+(-3u^3+42u^2-60u+21)\left(\frac{d}{du}y(u)\right)+(-7u^2+30u-22)\,y(u)=$

- Assume series solution for $y(u)$

$y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

☐ Rewrite ODE with series expansions

- ○ Convert $u^m\cdot y(u)$ to series expansion for $m=0..2$

$u^m\cdot y(u)=\sum_{k=0}^{\infty}a_k u^{k+r+m}$

- ○ Shift index using $k->k-m$

$u^m\cdot y(u)=\sum_{k=m}^{\infty}a_{k-m}u^{k+r}$

- ○ Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..3$

$u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,u^{k+r-1+m}$

- ○ Shift index using $k->k+1-m$

$u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,u^{k+r}$

- ○ Convert $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m=1..3$

$u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,u^{k+r-2+m}$

- ○ Shift index using $k->k+2-m$

$$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\, u^{k+r}$$

Rewrite ODE with series expansions

$$3a_0 r(4+3r)\, u^{-1+r} + (3a_1(1+r)(7+3r) - 2a_0(9r^2+21r+11))\, u^r + (3a_2(2+r)(10+3r) - 2a_1($$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $3r(4+3r) = 0$
- Values of r that satisfy the indicial equation
  $r \in \{0, -\frac{4}{3}\}$
- The coefficients of each power of u must be 0
  $[3a_1(1+r)(7+3r) - 2a_0(9r^2+21r+11) = 0, 3a_2(2+r)(10+3r) - 2a_1(9r^2+39r+41) + 3a_0(2$
- Solve for the dependent coefficient(s)
  $\left\{a_1 = \frac{2a_0(9r^2+21r+11)}{3(3r^2+10r+7)}, a_2 = \frac{a_0(243r^4+1593r^3+3699r^2+3567r+1174)}{9(9r^4+78r^3+241r^2+312r+140)}\right\}$
- Each term in the series must be 0, giving the recursion relation
  $9(-2a_k + a_{k-1} + a_{k+1})\, k^2 + 3(6(-2a_k + a_{k-1} + a_{k+1})\, r - 14a_k - a_{k-2} + 5a_{k-1} + 10a_{k+1})\, k + 9(-2a$
- Shift index using $k- >k+2$
  $9(-2a_{k+2} + a_{k+1} + a_{k+3})\,(k+2)^2 + 3(6(-2a_{k+2} + a_{k+1} + a_{k+3})\, r - 14a_{k+2} - a_k + 5a_{k+1} + 10a_{k+3})$
- Recursion relation that defines series solution to ODE
  $a_{k+3} = -\frac{9k^2a_{k+1} - 18k^2a_{k+2} + 18kra_{k+1} - 36kra_{k+2} + 9r^2a_{k+1} - 18r^2a_{k+2} - 3ka_k + 51ka_{k+1} - 114ka_{k+2} - 3ra_k + 51ra_{k+1} - 114ra_{k+2}}{3(3k^2+6kr+3r^2+22k+22r+39)}$
- Recursion relation for $r = 0$
  $a_{k+3} = -\frac{9k^2a_{k+1} - 18k^2a_{k+2} - 3ka_k + 51ka_{k+1} - 114ka_{k+2} - 7a_k + 72a_{k+1} - 178a_{k+2}}{3(3k^2+22k+39)}$
- Solution for $r = 0$
  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+3} = -\frac{9k^2a_{k+1} - 18k^2a_{k+2} - 3ka_k + 51ka_{k+1} - 114ka_{k+2} - 7a_k + 72a_{k+1} - 178a_{k+2}}{3(3k^2+22k+39)}, a_1 = \frac{22a_0}{21}, a_2 = \right.$
- Revert the change of variables $u = x+1$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k(x+1)^k, a_{k+3} = -\frac{9k^2a_{k+1} - 18k^2a_{k+2} - 3ka_k + 51ka_{k+1} - 114ka_{k+2} - 7a_k + 72a_{k+1} - 178a_{k+2}}{3(3k^2+22k+39)}, a_1 = \frac{22a_0}{21}, \right.$
- Recursion relation for $r = -\frac{4}{3}$
  $a_{k+3} = -\frac{9k^2a_{k+1} - 18k^2a_{k+2} - 3ka_k + 27ka_{k+1} - 66ka_{k+2} - 3a_k + 20a_{k+1} - 58a_{k+2}}{3(3k^2+14k+15)}$
- Solution for $r = -\frac{4}{3}$
  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k-\frac{4}{3}}, a_{k+3} = -\frac{9k^2a_{k+1} - 18k^2a_{k+2} - 3ka_k + 27ka_{k+1} - 66ka_{k+2} - 3a_k + 20a_{k+1} - 58a_{k+2}}{3(3k^2+14k+15)}, a_1 = \frac{2a_0}{3}, a_2 = \right.$
- Revert the change of variables $u = x+1$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k(x+1)^{k-\frac{4}{3}}, a_{k+3} = -\frac{9k^2a_{k+1} - 18k^2a_{k+2} - 3ka_k + 27ka_{k+1} - 66ka_{k+2} - 3a_k + 20a_{k+1} - 58a_{k+2}}{3(3k^2+14k+15)}, a_1 = \frac{2a_0}{3}, \right.$
- Combine solutions and rename parameters
  $\left[y(x) = \left(\sum_{k=0}^{\infty} a_k(x+1)^k\right) + \left(\sum_{k=0}^{\infty} b_k(x+1)^{k-\frac{4}{3}}\right), a_{k+3} = -\frac{9k^2a_{k+1} - 18k^2a_{k+2} - 3ka_k + 51ka_{k+1} - 114ka_{k+2} - 7a}{3(3k^2+22k+39)}\right.$

2.1.131 Problem 133

Internal problem ID [9303]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 133
Date solved : `Monday, January 27, 2025 at 06:01:14 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$36x^2(1-2x)\,y''+24x(1-9x)\,y'+(1-70x)\,y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.310 (sec)

Writing the ode as

$$\left(-72x^3+36x^2\right)y''+\left(-216x^2+24x\right)y'+(1-70x)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= -72x^3+36x^2 \\ B &= -216x^2+24x \\ C &= 1-70x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r=\frac{-32x^2+48x-9}{36\left(2x^2-x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -32x^2+48x-9 \\ t &= 36\left(2x^2-x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{-32x^2+48x-9}{36\left(2x^2-x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.246: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 4 - 2 \\
&= 2
\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 36(2x^2 - x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = \frac{1}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4x^2} + \frac{1}{3x} + \frac{7}{36\left(x - \frac{1}{2}\right)^2} - \frac{1}{3\left(x - \frac{1}{2}\right)}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2}
\end{aligned}$$

For the pole at $x = \frac{1}{2}$ let b be the coefficient of $\frac{1}{\left(x - \frac{1}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{7}{36}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{7}{6} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{1}{6}
\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{-32x^2+48x-9}{36\left(2x^2-x\right)^2}$$

Since the $\gcd(s,t)=1$. This gives $b=-\frac{2}{9}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2}+\sqrt{1+4b} = \frac{2}{3} \\
\alpha_\infty^- &= \frac{1}{2}-\sqrt{1+4b} = \frac{1}{3}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{-32x^2+48x-9}{36\left(2x^2-x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$
$\frac{1}{2}$	2	0	$\frac{7}{6}$	$-\frac{1}{6}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{2}{3}$	$\frac{1}{3}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{3}$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^+ + \alpha_{c_2}^-\right) \\
&= \frac{1}{3} - \left(\frac{1}{3}\right) \\
&= 0
\end{aligned}$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2}\right) + (-)[\sqrt{r}]_\infty \\
&= \frac{1}{2x} - \frac{1}{6\left(x-\frac{1}{2}\right)} + (-)(0) \\
&= \frac{1}{2x} - \frac{1}{6\left(x-\frac{1}{2}\right)} \\
&= \frac{-3+4x}{12x^2-6x}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p''+2\omega p'+(\omega'+\omega^2-r)\,p=0 \tag{1A}$$

Let

$$p(x)=1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(\frac{1}{2x}-\frac{1}{6\left(x-\frac{1}{2}\right)}\right)(0)+\left(\left(-\frac{1}{2x^2}+\frac{1}{6\left(x-\frac{1}{2}\right)^2}\right)+\left(\frac{1}{2x}-\frac{1}{6\left(x-\frac{1}{2}\right)}\right)^2-\left(\frac{-32x^2+48x-9}{36\left(2x^2-x\right)^2}\right.\right.$$

$$0=$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z''=rz$ is

$$\begin{aligned}
z_1(x)&=pe^{\int\omega\,dx}\\
&=\mathrm{e}^{\int\left(\frac{1}{2x}-\frac{1}{6\left(x-\frac{1}{2}\right)}\right)dx}\\
&=\frac{\sqrt{x}}{(-1+2x)^{1/6}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1&=z_1e^{\int-\frac{1}{2}\frac{B}{A}\,dx}\\
&=z_1e^{-\int\frac{1}{2}\frac{-216x^2+24x}{-72x^3+36x^2}\,dx}\\
&=z_1e^{-\frac{\ln(x)}{3}-\frac{7\ln(-1+2x)}{6}}\\
&=z_1\left(\frac{1}{x^{1/3}(-1+2x)^{7/6}}\right)
\end{aligned}$$

Which simplifies to

$$y_1=\frac{x^{1/6}}{(-1+2x)^{4/3}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2=y_1\int\frac{e^{\int-\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2&=y_1\int\frac{e^{\int-\frac{-216x^2+24x}{-72x^3+36x^2}\,dx}}{(y_1)^2}\,dx\\
&=y_1\int\frac{e^{-\frac{2\ln(x)}{3}-\frac{7\ln(-1+2x)}{3}}}{(y_1)^2}\,dx\\
&=y_1\Bigg(3(-1+2x)^{1/3}\\
&\quad-\ln\left((-1+2x)^{1/3}+1\right)+\frac{\ln\left((-1+2x)^{2/3}-(-1+2x)^{1/3}+1\right)}{2}-\sqrt{3}\arctan\left(\left(\frac{-1+2(-1+2x)^{1/3}}{3}\right.\right.
\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{x^{1/6}}{(-1+2x)^{4/3}}\right) \\
&\quad + c_2\left(\frac{x^{1/6}}{(-1+2x)^{4/3}}\left(3(-1+2x)^{1/3} - \ln\left((-1+2x)^{1/3}+1\right) + \frac{\ln\left((-1+2x)^{2/3}-(-1+2x)^{1/3}+1\right)}{2} - \sqrt{3}\ \right.\right.
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$36x^2(-2x+1)\left(\frac{d^2}{dx^2}y(x)\right) + 24x(1-9x)\left(\frac{d}{dx}y(x)\right) + (1-70x)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

Book : Collection of Kovacic problems
Section : section 1
Problem number : 134
Date solved : `Monday, January 27, 2025 at 06:01:15 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2(1+x)\,y''-x(3-x)\,y'+4y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.220 (sec)

Writing the ode as

$$x^2(1+x)\,y''+\left(x^2-3x\right)y'+4y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2(1+x) \\ B &= x^2-3x \\ C &= 4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{-x^2-10x-1}{4\left(x^2+x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -x^2-10x-1 \\ t &= 4\left(x^2+x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{-x^2-10x-1}{4\left(x^2+x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\,e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.248: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s)\\ &= 4-2\\ &= 2\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^2+x)^2$. There is a pole at $x=0$ of order 2. There is a pole at $x=-1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1,2,4,6,12]$$

Attempting to find a solution using case $n=1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4x^2} + \frac{2}{1+x} + \frac{2}{(1+x)^2} - \frac{2}{x}$$

For the pole at $x=-1$ let b be the coefficient of $\frac{1}{(1+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b=2$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2\\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1\end{aligned}$$

For the pole at $x=0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b=-\frac{1}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2}\\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{-x^2 - 10x - 1}{4(x^2 + x)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{1}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{-x^2 - 10x - 1}{4(x^2 + x)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
-1	2	0	2	-1
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^- - (\alpha_{c_1}^- + \alpha_{c_2}^+) \\
&= \frac{1}{2} - \left(-\frac{1}{2}\right) \\
&= 1
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x - c_1} \right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x - c_2} \right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{1}{1+x} + \frac{1}{2x} + (-)(0) \\
&= -\frac{1}{1+x} + \frac{1}{2x} \\
&= -\frac{x-1}{2x(1+x)}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{1+x} + \frac{1}{2x}\right)(1) + \left(\left(\frac{1}{(1+x)^2} - \frac{1}{2x^2}\right) + \left(-\frac{1}{1+x} + \frac{1}{2x}\right)^2 - \left(\frac{-x^2 - 10x - 1}{4\,(x^2+x)^2}\right)\right) = 0$$
$$\frac{1 + a_0}{x\,(1+x)} = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = -1\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x - 1$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx} \\
&= (x-1)\, \mathrm{e}^{\int \left(-\frac{1}{1+x} + \frac{1}{2x}\right) dx} \\
&= (x-1)\, \mathrm{e}^{\frac{\ln(x)}{2} - \ln(1+x)} \\
&= \frac{(x-1)\sqrt{x}}{1+x}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{x^2-3x}{x^2(1+x)}\, dx} \\
&= z_1 e^{\frac{3\ln(x)}{2} - 2\ln(1+x)} \\
&= z_1 \left(\frac{x^{3/2}}{(1+x)^2}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{x^2(x-1)}{(1+x)^3}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x^2-3x}{x^2(1+x)}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{3\ln(x) - 4\ln(1+x)}}{(y_1)^2}\, dx \\
&= y_1 \left(-\frac{4}{x-1} + \ln(x)\right)
\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{x^2(x-1)}{(1+x)^3} \right) + c_2 \left(\frac{x^2(x-1)}{(1+x)^3} \left(-\frac{4}{x-1} + \ln(x) \right) \right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2(x+1)\left(\frac{d^2}{dx^2}y(x)\right) - x(-x+3)\left(\frac{d}{dx}y(x)\right) + 4y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$
- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{4y(x)}{(x+1)x^2} - \frac{(x-3)\left(\frac{d}{dx}y(x)\right)}{x(x+1)}$
- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x) + \frac{(x-3)\left(\frac{d}{dx}y(x)\right)}{x(x+1)} + \frac{4y(x)}{(x+1)x^2} = 0$

□ Check to see if x_0 is a regular singular point

  - Define functions

    $\left[P_2(x) = \frac{x-3}{x(x+1)}, P_3(x) = \frac{4}{(x+1)x^2}\right]$
  - $(x+1) \cdot P_2(x)$ is analytic at $x = -1$

    $\left((x+1) \cdot P_2(x)\right)\Big|_{x=-1} = 4$
  - $(x+1)^2 \cdot P_3(x)$ is analytic at $x = -1$

    $\left((x+1)^2 \cdot P_3(x)\right)\Big|_{x=-1} = 0$
  - $x = -1$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = -1$
- Multiply by denominators

  $x^2(x+1)\left(\frac{d^2}{dx^2}y(x)\right) + x(x-3)\left(\frac{d}{dx}y(x)\right) + 4y(x) = 0$
- Change variables using $x = u - 1$ so that the regular singular point is at $u = 0$

  $(u^3 - 2u^2 + u)\left(\frac{d^2}{du^2}y(u)\right) + (u^2 - 5u + 4)\left(\frac{d}{du}y(u)\right) + 4y(u) = 0$
- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

□ Rewrite ODE with series expansions

  - Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..2$

    $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, u^{k+r-1+m}$
  - Shift index using $k- >k+1-m$

    $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$
  - Convert $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m = 1..3$

$$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, u^{k+r-2+m}$$

- Shift index using $k->k+2-m$

$$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\, u^{k+r}$$

Rewrite ODE with series expansions

$$a_0 r(3+r)\, u^{-1+r} + \left(a_1(1+r)(4+r) - a_0(2r^2+3r-4)\right) u^r + \left(\sum_{k=1}^{\infty} \left(a_{k+1}(k+1+r)(k+4+r) - \right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$r(3+r) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \{-3, 0\}$$

- Each term must be 0

$$a_1(1+r)(4+r) - a_0(2r^2+3r-4) = 0$$

- Each term in the series must be 0, giving the recursion relation

$$a_{k+1}(k+1+r)(k+4+r) - a_k(2k^2+4kr+2r^2+3k+3r-4) + a_{k-1}(k+r-1)^2 = 0$$

- Shift index using $k->k+1$

$$a_{k+2}(k+2+r)(k+5+r) - a_{k+1}\left(2(k+1)^2+4(k+1)\, r+2r^2+3k-1+3r\right) + a_k(k+r)^2 = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+2} = -\frac{k^2a_k-2k^2a_{k+1}+2kra_k-4kra_{k+1}+r^2a_k-2r^2a_{k+1}-7ka_{k+1}-7ra_{k+1}-a_{k+1}}{(k+2+r)(k+5+r)}$$

- Recursion relation for $r = -3$

$$a_{k+2} = -\frac{k^2a_k-2k^2a_{k+1}-6ka_k+5ka_{k+1}+9a_k+2a_{k+1}}{(k-1)(k+2)}$$

- Series not valid for $r = -3$, division by 0 in the recursion relation at $k = 1$

$$a_{k+2} = -\frac{k^2a_k-2k^2a_{k+1}-6ka_k+5ka_{k+1}+9a_k+2a_{k+1}}{(k-1)(k+2)}$$

- Recursion relation for $r = 0$

$$a_{k+2} = -\frac{k^2a_k-2k^2a_{k+1}-7ka_{k+1}-a_{k+1}}{(k+2)(k+5)}$$

- Solution for $r = 0$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+2} = -\frac{k^2a_k-2k^2a_{k+1}-7ka_{k+1}-a_{k+1}}{(k+2)(k+5)}, 4a_1+4a_0 = 0\right]$$

- Revert the change of variables $u = x+1$

$$\left[y(x) = \sum_{k=0}^{\infty} a_k(x+1)^k, a_{k+2} = -\frac{k^2a_k-2k^2a_{k+1}-7ka_{k+1}-a_{k+1}}{(k+2)(k+5)}, 4a_1+4a_0 = 0\right]$$

2.1.133 Problem 135

Internal problem ID [9305]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 135
Date solved : `Monday, January 27, 2025 at 06:01:16 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2(1-2x)\,y''-x(5-4x)\,y'+(9-4x)\,y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.216 (sec)

Writing the ode as

$$\left(-2x^3+x^2\right)y''+\left(4x^2-5x\right)y'+(9-4x)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A&=-2x^3+x^2\\ B&=4x^2-5x\\ C&=9-4x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r&=\frac{s}{t}\\ &=\frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{8x-1}{4\left(2x^2-x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s&=8x-1\\ t&=4\left(2x^2-x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{8x-1}{4\left(2x^2-x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.250: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 4 - 1 \\
&= 3
\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(2x^2 - x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = \frac{1}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 3 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 3 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{3}{4\left(x - \frac{1}{2}\right)^2} - \frac{1}{x - \frac{1}{2}} + \frac{1}{x} - \frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2}
\end{aligned}$$

For the pole at $x = \frac{1}{2}$ let b be the coefficient of $\frac{1}{\left(x - \frac{1}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{3}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{1}{2}
\end{aligned}$$

Since the order of r at ∞ is $3 > 2$ then

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= 0 \\
\alpha_\infty^- &= 1
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{8x - 1}{4\left(2x^2 - x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$
$\frac{1}{2}$	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
3	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = 0$ then

$$
\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^+ + \alpha_{c_2}^-\right) \\
&= 0 - (0) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

Substituting the above values in the above results in

$$
\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x - c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x - c_2} \right) + (+)[\sqrt{r}]_\infty \\
&= \frac{1}{2x} - \frac{1}{2\left(x - \frac{1}{2}\right)} + (0) \\
&= \frac{1}{2x} - \frac{1}{2\left(x - \frac{1}{2}\right)} \\
&= -\frac{1}{2x\left(-1 + 2x\right)}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(\frac{1}{2x}-\frac{1}{2\left(x-\frac{1}{2}\right)}\right)(0)+\left(\left(-\frac{1}{2x^2}+\frac{1}{2\left(x-\frac{1}{2}\right)^2}\right)+\left(\frac{1}{2x}-\frac{1}{2\left(x-\frac{1}{2}\right)}\right)^2-\left(\frac{8x-1}{4\left(2x^2-x\right)^2}\right)\right)=$$
$$0=0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z''=rz$ is

$$\begin{aligned}
z_1(x) &= pe^{\int \omega\,dx} \\
&= \mathrm{e}^{\int \left(\frac{1}{2x}-\frac{1}{2\left(x-\frac{1}{2}\right)}\right)dx} \\
&= \frac{\sqrt{x}}{\sqrt{-1+2x}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{4x^2-5x}{-2x^3+x^2}\,dx} \\
&= z_1 e^{-\frac{3\ln(-1+2x)}{2}+\frac{5\ln(x)}{2}} \\
&= z_1\left(\frac{x^{5/2}}{(-1+2x)^{3/2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1=\frac{x^3}{(-1+2x)^2}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2=y_1\int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1\int \frac{e^{\int -\frac{4x^2-5x}{-2x^3+x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1\int \frac{e^{-3\ln(-1+2x)+5\ln(x)}}{(y_1)^2}\,dx \\
&= y_1(2x-\ln(x))
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1y_1+c_2y_2 \\
&= c_1\left(\frac{x^3}{(-1+2x)^2}\right)+c_2\left(\frac{x^3}{(-1+2x)^2}(2x-\ln(x))\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2(-2x+1)\left(\frac{d^2}{dx^2}y(x)\right)-x(5-4x)\left(\frac{d}{dx}y(x)\right)+(9-4x)\,y(x)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x)=-\frac{(-9+4x)y(x)}{x^2(2x-1)}+\frac{(-5+4x)\left(\frac{d}{dx}y(x)\right)}{x(2x-1)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x)-\frac{(-5+4x)\left(\frac{d}{dx}y(x)\right)}{x(2x-1)}+\frac{(-9+4x)y(x)}{x^2(2x-1)}=0$

- □ Check to see if x_0 is a regular singular point
  - ◦ Define functions

    $\left[P_2(x)=-\frac{-5+4x}{x(2x-1)},P_3(x)=\frac{-9+4x}{x^2(2x-1)}\right]$
  - ◦ $x\cdot P_2(x)$ is analytic at $x=0$

    $\left(x\cdot P_2(x)\right)\bigg|_{x=0}=-5$
  - ◦ $x^2\cdot P_3(x)$ is analytic at $x=0$

    $\left(x^2\cdot P_3(x)\right)\bigg|_{x=0}=9$
  - ◦ $x=0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=0$

- Multiply by denominators

  $x^2(2x-1)\left(\frac{d^2}{dx^2}y(x)\right)-x(-5+4x)\left(\frac{d}{dx}y(x)\right)+(-9+4x)\,y(x)=0$

- Assume series solution for $y(x)$

  $y(x)=\sum_{k=0}^{\infty}a_kx^{k+r}$

- □ Rewrite ODE with series expansions
  - ◦ Convert $x^m\cdot y(x)$ to series expansion for $m=0..1$

    $x^m\cdot y(x)=\sum_{k=0}^{\infty}a_kx^{k+r+m}$
  - ◦ Shift index using $k->k-m$

    $x^m\cdot y(x)=\sum_{k=m}^{\infty}a_{k-m}x^{k+r}$
  - ◦ Convert $x^m\cdot\left(\frac{d}{dx}y(x)\right)$ to series expansion for $m=1..2$

    $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,x^{k+r-1+m}$
  - ◦ Shift index using $k->k+1-m$

    $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,x^{k+r}$
  - ◦ Convert $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m=2..3$

    $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,x^{k+r-2+m}$
  - ◦ Shift index using $k->k+2-m$

    $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=-2+m}^{\infty}a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$

  Rewrite ODE with series expansions

$$-a_0(-3+r)^2 x^r + \left(\sum_{k=1}^{\infty} \left(-a_k(k+r-3)^2 + 2a_{k-1}(k+r-2)(k+r-3)\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $-(-3+r)^2 = 0$
- Values of r that satisfy the indicial equation
  $r = 3$
- Each term in the series must be 0, giving the recursion relation
  $-a_k(k+r-3)^2 + 2a_{k-1}(k+r-2)(k+r-3) = 0$
- Shift index using $k- >k+1$
  $-a_{k+1}(k+r-2)^2 + 2a_k(k+r-1)(k+r-2) = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+1} = \frac{2a_k(k+r-1)}{k+r-2}$
- Recursion relation for $r = 3$
  $a_{k+1} = \frac{2a_k(k+2)}{k+1}$
- Solution for $r = 3$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+3}, a_{k+1} = \frac{2a_k(k+2)}{k+1}\right]$

2.1.134 Problem 136

Internal problem ID [9306]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 136
Date solved : `Monday, January 27, 2025 at 06:01:16 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$2x^2(2+x)\,y''+x^2y'+(1-x)\,y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.202 (sec)

Writing the ode as

$$\left(2x^3+4x^2\right)y''+x^2y'+(1-x)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=2x^3+4x^2\\B&=x^2\\C&=1-x\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned}r&=\frac{s}{t}\\&=\frac{2AB'-2BA'+B^2-4AC}{4A^2}\end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r=\frac{5x^2+8x-16}{16\left(x^2+2x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned}s&=5x^2+8x-16\\t&=16\left(x^2+2x\right)^2\end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{5x^2+8x-16}{16\left(x^2+2x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.252: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16(x^2 + 2x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -2$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4x^2} + \frac{3}{8x} - \frac{3}{8(2+x)} - \frac{3}{16(2+x)^2}$$

For the pole at $x = -2$ let b be the coefficient of $\frac{1}{(2+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{4} \end{aligned}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{5x^2 + 8x - 16}{16\left(x^2 + 2x\right)^2}$$

Since the gcd$(s,t) = 1$. This gives $b = \frac{5}{16}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{5}{4} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{1}{4}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{5x^2 + 8x - 16}{16\left(x^2 + 2x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
-2	2	0	$\frac{3}{4}$	$\frac{1}{4}$
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{5}{4}$	$-\frac{1}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{5}{4}$ then

$$\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^+ + \alpha_{c_2}^+\right) \\
&= \frac{5}{4} - \left(\frac{5}{4}\right) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x - c_1} \right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x - c_2} \right) + (+)[\sqrt{r}]_\infty \\
&= \frac{3}{4\left(2 + x\right)} + \frac{1}{2x} + (0) \\
&= \frac{3}{4\left(2 + x\right)} + \frac{1}{2x} \\
&= \frac{5x + 4}{4x\left(2 + x\right)}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{3}{4(2+x)} + \frac{1}{2x}\right)(0) + \left(\left(-\frac{3}{4(2+x)^2} - \frac{1}{2x^2}\right) + \left(\frac{3}{4(2+x)} + \frac{1}{2x}\right)^2 - \left(\frac{5x^2+8x-16}{16(x^2+2x)^2}\right)\right) = 0$$
$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega\, dx} \\ &= e^{\int \left(\frac{3}{4(2+x)} + \frac{1}{2x}\right) dx} \\ &= (2+x)^{3/4} \sqrt{x} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{x^2}{2x^3+4x^2}\, dx} \\ &= z_1 e^{-\frac{\ln(2+x)}{4}} \\ &= z_1 \left(\frac{1}{(2+x)^{1/4}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \sqrt{2+x}\,\sqrt{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{x^2}{2x^3+4x^2}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-\frac{\ln(2+x)}{2}}}{(y_1)^2}\, dx \\ &= y_1 \left(-\frac{\sqrt{2}\,\operatorname{arctanh}\left(\frac{\sqrt{2+x}\,\sqrt{2}}{2}\right)}{2} + \frac{1}{\sqrt{2+x}}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\sqrt{2+x}\,\sqrt{x}\right) + c_2\left(\sqrt{2+x}\,\sqrt{x}\left(-\frac{\sqrt{2}\,\operatorname{arctanh}\left(\frac{\sqrt{2+x}\,\sqrt{2}}{2}\right)}{2} + \frac{1}{\sqrt{2+x}}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$2x^2(x+2)\left(\frac{d^2}{dx^2}y(x)\right)+x^2\left(\frac{d}{dx}y(x)\right)+(1-x)\,y(x)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x)=\frac{(x-1)y(x)}{2(x+2)x^2}-\frac{\frac{d}{dx}y(x)}{2(x+2)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x)+\frac{\frac{d}{dx}y(x)}{2(x+2)}-\frac{(x-1)y(x)}{2(x+2)x^2}=0$

□ Check to see if x_0 is a regular singular point

- ○ Define functions

  $\left[P_2(x)=\frac{1}{2(x+2)},P_3(x)=-\frac{x-1}{2(x+2)x^2}\right]$

- ○ $(x+2)\cdot P_2(x)$ is analytic at $x=-2$

  $\left((x+2)\cdot P_2(x)\right)\bigg|_{x=-2}=\frac{1}{2}$

- ○ $(x+2)^2\cdot P_3(x)$ is analytic at $x=-2$

  $\left((x+2)^2\cdot P_3(x)\right)\bigg|_{x=-2}=0$

- ○ $x=-2$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=-2$

- Multiply by denominators

  $2x^2(x+2)\left(\frac{d^2}{dx^2}y(x)\right)+x^2\left(\frac{d}{dx}y(x)\right)+(1-x)\,y(x)=0$

- Change variables using $x=u-2$ so that the regular singular point is at $u=0$

  $(2u^3-8u^2+8u)\left(\frac{d^2}{du^2}y(u)\right)+(u^2-4u+4)\left(\frac{d}{du}y(u)\right)+(3-u)\,y(u)=0$

- Assume series solution for $y(u)$

  $y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

□ Rewrite ODE with series expansions

- ○ Convert $u^m\cdot y(u)$ to series expansion for $m=0..1$

  $u^m\cdot y(u)=\sum_{k=0}^{\infty}a_k u^{k+r+m}$

- ○ Shift index using $k->k-m$

  $u^m\cdot y(u)=\sum_{k=m}^{\infty}a_{k-m}u^{k+r}$

- ○ Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..2$

  $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,u^{k+r-1+m}$

- ○ Shift index using $k->k+1-m$

  $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,u^{k+r}$

- ○ Convert $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m=1..3$

  $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,u^{k+r-2+m}$

- ○ Shift index using $k->k+2-m$

$$u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=-2+m}^{\infty}a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,u^{k+r}$$

Rewrite ODE with series expansions

$$4a_0r(-1+2r)\,u^{-1+r}+\left(4a_1(1+r)\,(1+2r)-a_0(8r^2-4r-3)\right)u^r+\left(\sum_{k=1}^{\infty}(4a_{k+1}(k+1+r)\,(2k+$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$4r(-1+2r)=0$$

- Values of r that satisfy the indicial equation

$$r\in\left\{0,\frac{1}{2}\right\}$$

- Each term must be 0

$$4a_1(1+r)\,(1+2r)-a_0(8r^2-4r-3)=0$$

- Each term in the series must be 0, giving the recursion relation

$$2(-4a_k+a_{k-1}+4a_{k+1})\,k^2+(4(-4a_k+a_{k-1}+4a_{k+1})\,r+4a_k-5a_{k-1}+12a_{k+1})\,k+2(-4a_k+a_{k-}$$

- Shift index using $k->k+1$

$$2(-4a_{k+1}+a_k+4a_{k+2})\,(k+1)^2+(4(-4a_{k+1}+a_k+4a_{k+2})\,r+4a_{k+1}-5a_k+12a_{k+2})\,(k+1)+2$$

- Recursion relation that defines series solution to ODE

$$a_{k+2}=-\frac{2k^2a_k-8k^2a_{k+1}+4kra_k-16kra_{k+1}+2r^2a_k-8r^2a_{k+1}-ka_k-12ka_{k+1}-ra_k-12ra_{k+1}-a_k-a_{k+1}}{4(2k^2+4kr+2r^2+7k+7r+6)}$$

- Recursion relation for $r=0$

$$a_{k+2}=-\frac{2k^2a_k-8k^2a_{k+1}-ka_k-12ka_{k+1}-a_k-a_{k+1}}{4(2k^2+7k+6)}$$

- Solution for $r=0$

$$\left[y(u)=\sum_{k=0}^{\infty}a_ku^k,a_{k+2}=-\frac{2k^2a_k-8k^2a_{k+1}-ka_k-12ka_{k+1}-a_k-a_{k+1}}{4(2k^2+7k+6)},4a_1+3a_0=0\right]$$

- Revert the change of variables $u=x+2$

$$\left[y(x)=\sum_{k=0}^{\infty}a_k(x+2)^k,a_{k+2}=-\frac{2k^2a_k-8k^2a_{k+1}-ka_k-12ka_{k+1}-a_k-a_{k+1}}{4(2k^2+7k+6)},4a_1+3a_0=0\right]$$

- Recursion relation for $r=\frac{1}{2}$

$$a_{k+2}=-\frac{2k^2a_k-8k^2a_{k+1}+ka_k-20ka_{k+1}-a_k-9a_{k+1}}{4(2k^2+9k+10)}$$

- Solution for $r=\frac{1}{2}$

$$\left[y(u)=\sum_{k=0}^{\infty}a_ku^{k+\frac{1}{2}},a_{k+2}=-\frac{2k^2a_k-8k^2a_{k+1}+ka_k-20ka_{k+1}-a_k-9a_{k+1}}{4(2k^2+9k+10)},12a_1+3a_0=0\right]$$

- Revert the change of variables $u=x+2$

$$\left[y(x)=\sum_{k=0}^{\infty}a_k(x+2)^{k+\frac{1}{2}},a_{k+2}=-\frac{2k^2a_k-8k^2a_{k+1}+ka_k-20ka_{k+1}-a_k-9a_{k+1}}{4(2k^2+9k+10)},12a_1+3a_0=0\right]$$

- Combine solutions and rename parameters

$$\left[y(x)=\left(\sum_{k=0}^{\infty}a_k(x+2)^k\right)+\left(\sum_{k=0}^{\infty}b_k(x+2)^{k+\frac{1}{2}}\right),a_{k+2}=-\frac{2k^2a_k-8k^2a_{k+1}-ka_k-12ka_{k+1}-a_k-a_{k+1}}{4(2k^2+7k+6)},4a_1+$$

2.1.135 Problem 137

Internal problem ID [9307]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 137
Date solved : `Monday, January 27, 2025 at 06:01:17 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$2x^2(1+x)\,y''-x(6-x)\,y'+(8-x)\,y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.206 (sec)

Writing the ode as

$$\left(2x^3+2x^2\right)y''+\left(x^2-6x\right)y'+(8-x)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2x^3+2x^2 \\ B &= x^2-6x \\ C &= 8-x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{5x^2-20x-4}{16\left(x^2+x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 5x^2-20x-4 \\ t &= 16\left(x^2+x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{5x^2-20x-4}{16\left(x^2+x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.254: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16(x^2 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{3}{4\,(1+x)} + \frac{21}{16\,(1+x)^2} - \frac{1}{4x^2} - \frac{3}{4x}$$

For the pole at $x = -1$ let b be the coefficient of $\frac{1}{(1+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{21}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{4} \end{aligned}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{5x^2 - 20x - 4}{16\left(x^2 + x\right)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{5}{16}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{4} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{4}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{5x^2 - 20x - 4}{16\left(x^2 + x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
-1	2	0	$\frac{7}{4}$	$-\frac{3}{4}$
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{5}{4}$	$-\frac{1}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -\frac{1}{4}$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^+\right) \\
&= -\frac{1}{4} - \left(-\frac{1}{4}\right) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x - c_1}\right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x - c_2}\right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{3}{4(1+x)} + \frac{1}{2x} + (-)(0) \\
&= -\frac{3}{4(1+x)} + \frac{1}{2x} \\
&= -\frac{x-2}{4x(1+x)}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{3}{4(1+x)} + \frac{1}{2x}\right)(0) + \left(\left(\frac{3}{4(1+x)^2} - \frac{1}{2x^2}\right) + \left(-\frac{3}{4(1+x)} + \frac{1}{2x}\right)^2 - \left(\frac{5x^2 - 20x - 4}{16(x^2+x)^2}\right)\right) = 0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx} \\
&= e^{\int \left(-\frac{3}{4(1+x)} + \frac{1}{2x}\right) dx} \\
&= \frac{\sqrt{x}}{(1+x)^{3/4}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{x^2 - 6x}{2x^3 + 2x^2}\, dx} \\
&= z_1 e^{-\frac{7\ln(1+x)}{4} + \frac{3\ln(x)}{2}} \\
&= z_1 \left(\frac{x^{3/2}}{(1+x)^{7/4}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{x^2}{(1+x)^{5/2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x^2 - 6x}{2x^3 + 2x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-\frac{7\ln(1+x)}{2} + 3\ln(x)}}{(y_1)^2}\, dx \\
&= y_1 \left(\frac{2(1+x)^{3/2}}{3} + 2\sqrt{1+x} + \ln\left(\sqrt{1+x} - 1\right) - \ln\left(1 + \sqrt{1+x}\right)\right)
\end{aligned}$$

Therefore the solution is

$$y = c_1 y_1 + c_2 y_2$$
$$= c_1 \left(\frac{x^2}{(1+x)^{5/2}}\right)$$
$$+ c_2 \left(\frac{x^2}{(1+x)^{5/2}} \left(\frac{2(1+x)^{3/2}}{3} + 2\sqrt{1+x} + \ln\left(\sqrt{1+x}-1\right) - \ln\left(1+\sqrt{1+x}\right)\right)\right)$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$2x^2(x+1)\left(\frac{d^2}{dx^2}y(x)\right) - x(-x+6)\left(\frac{d}{dx}y(x)\right) + (8-x)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = \frac{(-8+x)y(x)}{2x^2(x+1)} - \frac{(-6+x)\left(\frac{d}{dx}y(x)\right)}{2x(x+1)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x) + \frac{(-6+x)\left(\frac{d}{dx}y(x)\right)}{2x(x+1)} - \frac{(-8+x)y(x)}{2x^2(x+1)} = 0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

  $\left[P_2(x) = \frac{-6+x}{2x(x+1)}, P_3(x) = -\frac{-8+x}{2x^2(x+1)}\right]$

  ◦ $(x+1)\cdot P_2(x)$ is analytic at $x=-1$

  $\left((x+1)\cdot P_2(x)\right)\Big|_{x=-1} = \frac{7}{2}$

  ◦ $(x+1)^2\cdot P_3(x)$ is analytic at $x=-1$

  $\left((x+1)^2\cdot P_3(x)\right)\Big|_{x=-1} = 0$

  ◦ $x=-1$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = -1$

- Multiply by denominators

  $2x^2(x+1)\left(\frac{d^2}{dx^2}y(x)\right) + x(-6+x)\left(\frac{d}{dx}y(x)\right) + (8-x)\,y(x) = 0$

- Change variables using $x = u-1$ so that the regular singular point is at $u=0$

  $(2u^3-4u^2+2u)\left(\frac{d^2}{du^2}y(u)\right) + (u^2-8u+7)\left(\frac{d}{du}y(u)\right) + (9-u)\,y(u) = 0$

- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $u^m\cdot y(u)$ to series expansion for $m = 0..1$

  $u^m\cdot y(u) = \sum_{k=0}^{\infty} a_k u^{k+r+m}$

  ◦ Shift index using $k->k-m$

  $u^m\cdot y(u) = \sum_{k=m}^{\infty} a_{k-m} u^{k+r}$

  ◦ Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..2$

$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, u^{k+r-1+m}$

- Shift index using $k->k+1-m$

  $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$

- Convert $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m=1..3$

  $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, u^{k+r-2+m}$

- Shift index using $k->k+2-m$

  $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, u^{k+r}$

  Rewrite ODE with series expansions

  $a_0 r(5+2r)\, u^{-1+r} + \left(a_1(1+r)\,(7+2r) - a_0(4r^2+4r-9)\right) u^r + \left(\sum_{k=1}^{\infty} \left(a_{k+1}(k+1+r)\,(2k+7+\right.\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r(5+2r)=0$

- Values of r that satisfy the indicial equation

  $r \in \left\{0, -\frac{5}{2}\right\}$

- Each term must be 0

  $a_1(1+r)\,(7+2r) - a_0(4r^2+4r-9) = 0$

- Each term in the series must be 0, giving the recursion relation

  $(-4a_k + 2a_{k-1} + 2a_{k+1})\, k^2 + ((-8a_k + 4a_{k-1} + 4a_{k+1})\, r - 4a_k - 5a_{k-1} + 9a_{k+1})\, k + (-4a_k + 2a$

- Shift index using $k->k+1$

  $(-4a_{k+1} + 2a_k + 2a_{k+2})\,(k+1)^2 + ((-8a_{k+1} + 4a_k + 4a_{k+2})\, r - 4a_{k+1} - 5a_k + 9a_{k+2})\,(k+1) +$

- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{2k^2a_k - 4k^2a_{k+1} + 4kra_k - 8kra_{k+1} + 2r^2a_k - 4r^2a_{k+1} - ka_k - 12ka_{k+1} - ra_k - 12ra_{k+1} - a_k + a_{k+1}}{2k^2 + 4kr + 2r^2 + 13k + 13r + 18}$

- Recursion relation for $r=0$

  $a_{k+2} = -\frac{2k^2a_k - 4k^2a_{k+1} - ka_k - 12ka_{k+1} - a_k + a_{k+1}}{2k^2 + 13k + 18}$

- Solution for $r=0$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+2} = -\frac{2k^2a_k - 4k^2a_{k+1} - ka_k - 12ka_{k+1} - a_k + a_{k+1}}{2k^2 + 13k + 18}, 7a_1 + 9a_0 = 0\right]$

- Revert the change of variables $u = x+1$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k(x+1)^k, a_{k+2} = -\frac{2k^2a_k - 4k^2a_{k+1} - ka_k - 12ka_{k+1} - a_k + a_{k+1}}{2k^2 + 13k + 18}, 7a_1 + 9a_0 = 0\right]$

- Recursion relation for $r = -\frac{5}{2}$

  $a_{k+2} = -\frac{2k^2a_k - 4k^2a_{k+1} - 11ka_k + 8ka_{k+1} + 14a_k + 6a_{k+1}}{2k^2 + 3k - 2}$

- Solution for $r = -\frac{5}{2}$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k-\frac{5}{2}}, a_{k+2} = -\frac{2k^2a_k - 4k^2a_{k+1} - 11ka_k + 8ka_{k+1} + 14a_k + 6a_{k+1}}{2k^2 + 3k - 2}, -3a_1 - 6a_0 = 0\right]$

- Revert the change of variables $u = x+1$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k(x+1)^{k-\frac{5}{2}}, a_{k+2} = -\frac{2k^2a_k - 4k^2a_{k+1} - 11ka_k + 8ka_{k+1} + 14a_k + 6a_{k+1}}{2k^2 + 3k - 2}, -3a_1 - 6a_0 = 0\right]$

- Combine solutions and rename parameters

  $\left[y(x) = \left(\sum_{k=0}^{\infty} a_k(x+1)^k\right) + \left(\sum_{k=0}^{\infty} b_k(x+1)^{k-\frac{5}{2}}\right), a_{k+2} = -\frac{2k^2a_k - 4k^2a_{k+1} - ka_k - 12ka_{k+1} - a_k + a_{k+1}}{2k^2 + 13k + 18}, 7a_1\right.$

Problem number : 138
Date solved : `Monday, January 27, 2025 at 06:01:17 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2(1+2x)\,y''+x(5+9x)\,y'+(4+3x)\,y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.227 (sec)

Writing the ode as

$$\left(2x^3+x^2\right)y''+\left(9x^2+5x\right)y'+(4+3x)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A&=2x^3+x^2\\ B&=9x^2+5x\\ C&=4+3x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r&=\frac{s}{t}\\ &=\frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{21x^2+6x-1}{4\left(2x^2+x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s&=21x^2+6x-1\\ t&=4\left(2x^2+x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{21x^2+6x-1}{4\left(2x^2+x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.256: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(2x^2 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -\frac{1}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4x^2} + \frac{5}{2x} + \frac{5}{16\left(x + \frac{1}{2}\right)^2} - \frac{5}{2\left(x + \frac{1}{2}\right)}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2} \end{aligned}$$

For the pole at $x = -\frac{1}{2}$ let b be the coefficient of $\frac{1}{\left(x+\frac{1}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{5}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{5}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{1}{4} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{21x^2 + 6x - 1}{4\left(2x^2 + x\right)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{21}{16}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{4} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{4}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{21x^2 + 6x - 1}{4\left(2x^2 + x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$
$-\frac{1}{2}$	2	0	$\frac{5}{4}$	$-\frac{1}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{7}{4}$	$-\frac{3}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{7}{4}$ then

$$\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^+ + \alpha_{c_2}^+\right) \\
&= \frac{7}{4} - \left(\frac{7}{4}\right) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1}\right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x-c_2}\right) + (+)[\sqrt{r}]_\infty \\
&= \frac{1}{2x} + \frac{5}{4\left(x+\frac{1}{2}\right)} + (0) \\
&= \frac{1}{2x} + \frac{5}{4\left(x+\frac{1}{2}\right)} \\
&= \frac{1+7x}{4x^2+2x}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{2x} + \frac{5}{4\left(x+\frac{1}{2}\right)}\right)(0) + \left(\left(-\frac{1}{2x^2} - \frac{5}{4\left(x+\frac{1}{2}\right)^2}\right) + \left(\frac{1}{2x} + \frac{5}{4\left(x+\frac{1}{2}\right)}\right)^2 - \left(\frac{21x^2+6x-1}{4\left(2x^2+x\right)^2}\right)\right) = 0$$

$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= \mathrm{e}^{\int \left(\frac{1}{2x} + \frac{5}{4\left(x+\frac{1}{2}\right)}\right) dx} \\ &= \sqrt{x}\,(1+2x)^{5/4} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{9x^2+5x}{2x^3+x^2} \, dx} \\ &= z_1 e^{-\frac{5\ln(x)}{2} + \frac{\ln(1+2x)}{4}} \\ &= z_1 \left(\frac{(1+2x)^{1/4}}{x^{5/2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{(1+2x)^{3/2}}{x^2}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{9x^2+5x}{2x^3+x^2} \, dx}}{(y_1)^2} \, dx \\ &= y_1 \int \frac{e^{-5\ln(x) + \frac{\ln(1+2x)}{2}}}{(y_1)^2} \, dx \\ &= y_1 \left(-\ln\left(\sqrt{1+2x}+1\right) + \frac{2}{3(1+2x)^{3/2}} + \frac{2}{\sqrt{1+2x}} + \ln\left(\sqrt{1+2x}-1\right)\right) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1y_1 + c_2y_2 \\
&= c_1\left(\frac{(1+2x)^{3/2}}{x^2}\right) \\
&\quad + c_2\left(\frac{(1+2x)^{3/2}}{x^2}\left(-\ln\left(\sqrt{1+2x}+1\right)+\frac{2}{3\,(1+2x)^{3/2}}+\frac{2}{\sqrt{1+2x}}+\ln\left(\sqrt{1+2x}-1\right)\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2(2x+1)\left(\frac{d^2}{dx^2}y(x)\right)+x(5+9x)\left(\frac{d}{dx}y(x)\right)+(3x+4)\,y(x)=0$

  - Convert $x^m\cdot y(x)$ to series expansion for $m=0..1$

    $x^m\cdot y(x)=\sum_{k=0}^{\infty}a_kx^{k+r+m}$
  - Shift index using $k->k-m$

    $x^m\cdot y(x)=\sum_{k=m}^{\infty}a_{k-m}x^{k+r}$
  - Convert $x^m\cdot\left(\frac{d}{dx}y(x)\right)$ to series expansion for $m=1..2$

    $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,x^{k+r-1+m}$
  - Shift index using $k->k+1-m$

$$x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$$

- Convert $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m = 2..3$

$$x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-2+m}$$

- Shift index using $k- >k+2-m$

$$x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0(2+r)^2 x^r + \left(\sum_{k=1}^{\infty} \left(a_k(k+r+2)^2 + a_{k-1}(k+r+2)\,(2k-1+2r)\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$(2+r)^2 = 0$$

- Values of r that satisfy the indicial equation

$$r = -2$$

- Each term in the series must be 0, giving the recursion relation

$$(k+r+2)\left(a_k(k+r+2) + a_{k-1}(2k-1+2r)\right) = 0$$

- Shift index using $k- >k+1$

$$(k+r+3)\left(a_{k+1}(k+r+3) + a_k(2k+2r+1)\right) = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1} = -\frac{a_k(2k+2r+1)}{k+r+3}$$

- Recursion relation for $r = -2$

$$a_{k+1} = -\frac{a_k(2k-3)}{k+1}$$

- Solution for $r = -2$

$$\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k-2}, a_{k+1} = -\frac{a_k(2k-3)}{k+1}\right]$$

2.1.137 Problem 139

Internal problem ID [9309]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 139
Date solved : `Monday, January 27, 2025 at 06:01:18 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2(1-2x)\,y''-x(5+4x)\,y'+(9+4x)\,y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.251 (sec)

Writing the ode as

$$\left(-2x^3+x^2\right)y''+\left(-4x^2-5x\right)y'+(9+4x)\,y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= -2x^3+x^2 \\ B &= -4x^2-5x \\ C &= 9+4x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{32x^2+56x-1}{4\left(2x^2-x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 32x^2+56x-1 \\ t &= 4\left(2x^2-x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{32x^2+56x-1}{4\left(2x^2-x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.258: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(2x^2 - x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = \frac{1}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{13}{x} - \frac{1}{4x^2} + \frac{35}{4\left(x - \frac{1}{2}\right)^2} - \frac{13}{x - \frac{1}{2}}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2} \end{aligned}$$

For the pole at $x = \frac{1}{2}$ let b be the coefficient of $\frac{1}{\left(x - \frac{1}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{35}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{7}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{5}{2} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{32x^2 + 56x - 1}{4\left(2x^2 - x\right)^2}$$

Since the $\gcd(s, t) = 1$. This gives $b = 2$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1 + 4b} = 2 \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1 + 4b} = -1
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{32x^2 + 56x - 1}{4\left(2x^2 - x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$
$\frac{1}{2}$	2	0	$\frac{7}{2}$	$-\frac{5}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	2	-1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -1$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^+ + \alpha_{c_2}^-\right) \\
&= -1 - (-2) \\
&= 1
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x - c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x - c_2} \right) + (-)[\sqrt{r}]_\infty \\
&= \frac{1}{2x} - \frac{5}{2\left(x - \frac{1}{2}\right)} + (-)(0) \\
&= \frac{1}{2x} - \frac{5}{2\left(x - \frac{1}{2}\right)} \\
&= \frac{-1 - 8x}{4x^2 - 2x}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{2x} - \frac{5}{2\left(x-\frac{1}{2}\right)}\right)(1) + \left(\left(-\frac{1}{2x^2} + \frac{5}{2\left(x-\frac{1}{2}\right)^2}\right) + \left(\frac{1}{2x} - \frac{5}{2\left(x-\frac{1}{2}\right)}\right)^2 - \left(\frac{32x^2+56x-1}{4\left(2x^2-x\right)^2}\right)\right)$$
$$\frac{-1+8a_0}{x\left(-1+2x\right)} = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\left\{a_0 = \frac{1}{8}\right\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x + \frac{1}{8}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \left(x + \frac{1}{8}\right) e^{\int \left(\frac{1}{2x} - \frac{5}{2\left(x-\frac{1}{2}\right)}\right) dx} \\
&= \left(x + \frac{1}{8}\right) e^{-\frac{5\ln(-1+2x)}{2} + \frac{\ln(x)}{2}} \\
&= \frac{\left(x+\frac{1}{8}\right)\sqrt{x}}{\left(-1+2x\right)^{5/2}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-4x^2-5x}{-2x^3+x^2} \, dx} \\
&= z_1 e^{-\frac{7\ln(-1+2x)}{2} + \frac{5\ln(x)}{2}} \\
&= z_1 \left(\frac{x^{5/2}}{\left(-1+2x\right)^{7/2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{x^3\left(x+\frac{1}{8}\right)}{\left(-1+2x\right)^6}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-4x^2-5x}{-2x^3+x^2} \, dx}}{\left(y_1\right)^2} \, dx \\
&= y_1 \int \frac{e^{-7\ln(-1+2x)+5\ln(x)}}{\left(y_1\right)^2} \, dx \\
&= y_1 \left(\frac{32x^3}{3} - 44x^2 + \frac{203x}{2} - \frac{3125}{16\left(1+8x\right)} - 64\ln\left(x\right)\right)
\end{aligned}$$

Therefore the solution is

$$y = c_1y_1 + c_2y_2$$
$$= c_1\left(\frac{x^3\left(x+\frac{1}{8}\right)}{\left(-1+2x\right)^6}\right) + c_2\left(\frac{x^3\left(x+\frac{1}{8}\right)}{\left(-1+2x\right)^6}\left(\frac{32x^3}{3} - 44x^2 + \frac{203x}{2} - \frac{3125}{16\left(1+8x\right)} - 64\ln\left(x\right)\right)\right)$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve
$x^2(-2x+1)\left(\frac{d^2}{dx^2}y(x)\right) - x(5+4x)\left(\frac{d}{dx}y(x)\right) + (4x+9)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2
  $\frac{d^2}{dx^2}y(x)$
- Isolate 2nd derivative
  $\frac{d^2}{dx^2}y(x) = \frac{(4x+9)y(x)}{x^2(2x-1)} - \frac{(5+4x)\left(\frac{d}{dx}y(x)\right)}{x(2x-1)}$
- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea
  $\frac{d^2}{dx^2}y(x) + \frac{(5+4x)\left(\frac{d}{dx}y(x)\right)}{x(2x-1)} - \frac{(4x+9)y(x)}{x^2(2x-1)} = 0$

□ Check to see if x_0 is a regular singular point
  - Define functions
    $\left[P_2(x) = \frac{5+4x}{x(2x-1)}, P_3(x) = -\frac{4x+9}{x^2(2x-1)}\right]$
  - $x \cdot P_2(x)$ is analytic at $x = 0$
    $\left(x \cdot P_2(x)\right)\Big|_{x=0} = -5$
  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$
    $\left(x^2 \cdot P_3(x)\right)\Big|_{x=0} = 9$
  - $x = 0$is a regular singular point
    Check to see if x_0 is a regular singular point
    $x_0 = 0$
- Multiply by denominators
  $x^2(2x-1)\left(\frac{d^2}{dx^2}y(x)\right) + x(5+4x)\left(\frac{d}{dx}y(x)\right) + (-4x-9)\,y(x) = 0$
- Assume series solution for $y(x)$
  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions
  - Convert $x^m \cdot y(x)$ to series expansion for $m = 0..1$
    $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$
  - Shift index using $k- >k-m$
    $x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$
  - Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m = 1..2$
    $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$
  - Shift index using $k- >k+1-m$

$$x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$$

- Convert $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m = 2..3$

$$x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-2+m}$$

- Shift index using $k- > k+2-m$

$$x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, x^{k+r}$$

Rewrite ODE with series expansions

$$-a_0(-3+r)^2 x^r + \left(\sum_{k=1}^{\infty} \left(-a_k(k+r-3)^2 + 2a_{k-1}(k+1+r)\,(k-2+r)\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$-(-3+r)^2 = 0$$

- Values of r that satisfy the indicial equation

$$r = 3$$

- Each term in the series must be 0, giving the recursion relation

$$-a_k(k+r-3)^2 + 2a_{k-1}(k+1+r)\,(k-2+r) = 0$$

- Shift index using $k- > k+1$

$$-a_{k+1}(k-2+r)^2 + 2a_k(k+r+2)\,(k+r-1) = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1} = \frac{2a_k(k+r+2)(k+r-1)}{(k-2+r)^2}$$

- Recursion relation for $r = 3$

$$a_{k+1} = \frac{2a_k(k+5)(k+2)}{(k+1)^2}$$

- Solution for $r = 3$

$$\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+3}, a_{k+1} = \frac{2a_k(k+5)(k+2)}{(k+1)^2}\right]$$

2.1.138 Problem 140

Internal problem ID [9310]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 140
Date solved : Monday, January 27, 2025 at 06:01:19 PM
CAS classification : [[_2nd_order, _with_linear_symmetries]]

Solve

$$x^2(1-x)\,y''+x(7+x)\,y'+(9-x)\,y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.260 (sec)

Writing the ode as

$$\left(-x^3+x^2\right)y''+\left(x^2+7x\right)y'+(9-x)\,y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= -x^3+x^2 \\ B &= x^2+7x \\ C &= 9-x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{-x^2+82x-1}{4\left(x^2-x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -x^2+82x-1 \\ t &= 4\left(x^2-x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{-x^2+82x-1}{4\left(x^2-x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.260: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^2 - x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = 1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{20}{-1+x} + \frac{20}{x} + \frac{20}{(-1+x)^2} - \frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

For the pole at $x = 1$ let b be the coefficient of $\frac{1}{(-1+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 20$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 5 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -4 \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{-x^2 + 82x - 1}{4\left(x^2 - x\right)^2}$$

Since the $\gcd(s, t) = 1$. This gives $b = -\frac{1}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{-x^2 + 82x - 1}{4\left(x^2 - x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$
1	2	0	5	-4

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^+ + \alpha_{c_2}^-\right) \\
&= \frac{1}{2} - \left(-\frac{7}{2}\right) \\
&= 4
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x - c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x - c_2} \right) + (-)[\sqrt{r}]_\infty \\
&= \frac{1}{2x} - \frac{4}{-1 + x} + (-)(0) \\
&= \frac{1}{2x} - \frac{4}{-1 + x} \\
&= -\frac{1 + 7x}{2x(-1 + x)}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 4$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = x^4 + a_3x^3 + a_2x^2 + a_1x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(12x^2 + 6xa_3 + 2a_2) + 2\left(\frac{1}{2x} - \frac{4}{-1+x}\right)(4x^3 + 3x^2a_3 + 2a_2x + a_1) + \left(\left(-\frac{1}{2x^2} + \frac{4}{(-1+x)^2}\right) + \left(\frac{1}{2x} - \right.\right.$$

$$\frac{(a_3 - 16)\, x^3 + (4a_2 - 9a_3)\, x^2}{x\,(-1}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 1, a_1 = 16, a_2 = 36, a_3 = 16\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^4 + 16x^3 + 36x^2 + 16x + 1$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= pe^{\int \omega\, dx} \\
&= (x^4 + 16x^3 + 36x^2 + 16x + 1)\, e^{\int \left(\frac{1}{2x} - \frac{4}{-1+x}\right) dx} \\
&= (x^4 + 16x^3 + 36x^2 + 16x + 1)\, e^{-4\ln(-1+x) + \frac{\ln(x)}{2}} \\
&= \frac{(x^4 + 16x^3 + 36x^2 + 16x + 1)\sqrt{x}}{(-1+x)^4}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{x^2+7x}{-x^3+x^2}\, dx} \\
&= z_1 e^{4\ln(-1+x) - \frac{7\ln(x)}{2}} \\
&= z_1 \left(\frac{(-1+x)^4}{x^{7/2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{x^4 + 16x^3 + 36x^2 + 16x + 1}{x^3}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x^2+7x}{-x^3+x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{8\ln(-1+x) - 7\ln(x)}}{(y_1)^2}\, dx \\
&= y_1 \left(\ln(x) - \frac{20\left(-2x^3 - \frac{15}{2}x^2 - \frac{14}{3}x - \frac{5}{12}\right)}{x^4 + 16x^3 + 36x^2 + 16x + 1}\right)
\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{x^4+16x^3+36x^2+16x+1}{x^3}\right) \\
&\quad + c_2\left(\frac{x^4+16x^3+36x^2+16x+1}{x^3}\left(\ln(x) - \frac{20\left(-2x^3-\frac{15}{2}x^2-\frac{14}{3}x-\frac{5}{12}\right)}{x^4+16x^3+36x^2+16x+1}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2(1-x)\left(\frac{d^2}{dx^2}y(x)\right)+x(7+x)\left(\frac{d}{dx}y(x)\right)+(9-x)\,y(x)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x)=-\frac{(x-9)y(x)}{x^2(x-1)}+\frac{(7+x)\left(\frac{d}{dx}y(x)\right)}{x(x-1)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x)-\frac{(7+x)\left(\frac{d}{dx}y(x)\right)}{x(x-1)}+\frac{(x-9)y(x)}{x^2(x-1)}=0$

- □ Check to see if x_0 is a regular singular point
  - Define functions

    $\left[P_2(x)=-\frac{7+x}{x(x-1)}, P_3(x)=\frac{x-9}{x^2(x-1)}\right]$

  - $x\cdot P_2(x)$ is analytic at $x=0$

    $\left.(x\cdot P_2(x))\right|_{x=0}=7$

  - $x^2\cdot P_3(x)$ is analytic at $x=0$

    $\left.(x^2\cdot P_3(x))\right|_{x=0}=9$

  - $x=0$is a regular singular point

    Check to see if x_0 is a regular singular point

    $x_0=0$

- Multiply by denominators

  $x^2(x-1)\left(\frac{d^2}{dx^2}y(x)\right)-x(7+x)\left(\frac{d}{dx}y(x)\right)+(x-9)\,y(x)=0$

- Assume series solution for $y(x)$

  $y(x)=\sum_{k=0}^{\infty} a_k x^{k+r}$

- □ Rewrite ODE with series expansions
  - Convert $x^m\cdot y(x)$ to series expansion for $m=0..1$

    $x^m\cdot y(x)=\sum_{k=0}^{\infty} a_k x^{k+r+m}$

  - Shift index using $k->k-m$

    $x^m\cdot y(x)=\sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

  - Convert $x^m\cdot\left(\frac{d}{dx}y(x)\right)$ to series expansion for $m=1..2$

    $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$

- Shift index using $k->k+1-m$

  $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$
- Convert $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m = 2..3$

  $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r-2+m}$
- Shift index using $k->k+2-m$

  $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$

  Rewrite ODE with series expansions

  $-a_0(3+r)^2\,x^r + \left(\sum_{k=1}^{\infty} \left(-a_k(k+r+3)^2 + a_{k-1}(k-2+r)^2\right)x^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $-(3+r)^2 = 0$
- Values of r that satisfy the indicial equation

  $r = -3$
- Each term in the series must be 0, giving the recursion relation

  $-a_k(k+r+3)^2 + a_{k-1}(k-2+r)^2 = 0$
- Shift index using $k->k+1$

  $-a_{k+1}(k+4+r)^2 + a_k(k+r-1)^2 = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+1} = \frac{a_k(k+r-1)^2}{(k+4+r)^2}$
- Recursion relation for $r = -3$; series terminates at $k = 4$

  $a_{k+1} = \frac{a_k(k-4)^2}{(k+1)^2}$
- Apply recursion relation for $k = 0$

  $a_1 = 16a_0$
- Apply recursion relation for $k = 1$

  $a_2 = \frac{9a_1}{4}$
- Express in terms of a_0

  $a_2 = 36a_0$
- Apply recursion relation for $k = 2$

  $a_3 = \frac{4a_2}{9}$
- Express in terms of a_0

  $a_3 = 16a_0$
- Apply recursion relation for $k = 3$

  $a_4 = \frac{a_3}{16}$
- Express in terms of a_0

  $a_4 = a_0$
- Terminating series solution of the ODE for $r = -3$. Use reduction of order to find the second lin

  $y(x) = a_0 \cdot (x^4 + 16x^3 + 36x^2 + 16x + 1)$

Section : section 1
Problem number : 141
Date solved : `Monday, January 27, 2025 at 06:01:19 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' - x(-x^2+1)\,y' + (x^2+1)\,y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.253 (sec)

Writing the ode as

$$x^2y'' + (x^3-x)\,y' + (x^2+1)\,y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= x^3 - x \\ C &= x^2+1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^4 - 4x^2 - 1}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^4 - 4x^2 - 1 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^4 - 4x^2 - 1}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.262: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 4 \\ &= -2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{x^2}{4} - 1 - \frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x}{2} - \frac{1}{x} - \frac{5}{4x^3} - \frac{5}{2x^5} - \frac{105}{16x^7} - \frac{155}{8x^9} - \frac{1965}{32x^{11}} - \frac{3265}{16x^{13}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= \frac{x}{2}\end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $([\sqrt{r}]_\infty)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$([\sqrt{r}]_\infty)^2 = \frac{x^2}{4}$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned}r &= \frac{s}{t} \\ &= \frac{x^4 - 4x^2 - 1}{4x^2} \\ &= Q + \frac{R}{4x^2} \\ &= \left(\frac{x^2}{4} - 1\right) + \left(-\frac{1}{4x^2}\right) \\ &= \frac{x^2}{4} - 1 - \frac{1}{4x^2}\end{aligned}$$

We see that the coefficient of the term x in the quotient is -1. Now b can be found.

$$\begin{aligned}b &= (-1) - (0) \\ &= -1\end{aligned}$$

Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= \frac{x}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-1}{\frac{1}{2}} - 1\right) &&= -\frac{3}{2} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-1}{\frac{1}{2}} - 1\right) &&= \frac{1}{2}\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^4 - 4x^2 - 1}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-2	$\frac{x}{2}$	$-\frac{3}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^- - (\alpha_{c_1}^+) \\ &= \frac{1}{2} - \left(\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{1}{2x} + (-)\left(\frac{x}{2}\right) \\ &= \frac{1}{2x} - \frac{x}{2} \\ &= \frac{1}{2x} - \frac{x}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(\frac{1}{2x} - \frac{x}{2}\right)(0) + \left(\left(-\frac{1}{2x^2} - \frac{1}{2}\right) + \left(\frac{1}{2x} - \frac{x}{2}\right)^2 - \left(\frac{x^4 - 4x^2 - 1}{4x^2}\right) \right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega\, dx} \\ &= e^{\int \left(\frac{1}{2x} - \frac{x}{2}\right) dx} \\ &= \sqrt{x}\, e^{-\frac{x^2}{4}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{x^3-x}{x^2}\,dx} \\
&= z_1 e^{-\frac{x^2}{4}+\frac{\ln(x)}{2}} \\
&= z_1\left(\sqrt{x}\,\mathrm{e}^{-\frac{x^2}{4}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = x\,\mathrm{e}^{-\frac{x^2}{2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x^3-x}{x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{x^2}{2}+\ln(x)}}{(y_1)^2}\,dx \\
&= y_1\left(-\frac{\mathrm{Ei}_1\left(-\frac{x^2}{2}\right)}{2}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(x\,\mathrm{e}^{-\frac{x^2}{2}}\right) + c_2\left(x\,\mathrm{e}^{-\frac{x^2}{2}}\left(-\frac{\mathrm{Ei}_1\left(-\frac{x^2}{2}\right)}{2}\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2\left(\frac{d^2}{dx^2}y(x)\right) - x(-x^2+1)\left(\frac{d}{dx}y(x)\right) + (x^2+1)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{(x^2+1)y(x)}{x^2} - \frac{(x^2-1)\left(\frac{d}{dx}y(x)\right)}{x}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x) + \frac{(x^2-1)\left(\frac{d}{dx}y(x)\right)}{x} + \frac{(x^2+1)y(x)}{x^2} = 0$

- ☐ Check to see if $x_0 = 0$ is a regular singular point
  - ○ Define functions

$\left[P_2(x) = \frac{x^2-1}{x}, P_3(x) = \frac{x^2+1}{x^2}\right]$

- $x \cdot P_2(x)$ is analytic at $x = 0$

  $(x \cdot P_2(x))\Big|_{x=0} = -1$

- $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $(x^2 \cdot P_3(x))\Big|_{x=0} = 1$

- $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $x^2\left(\frac{d^2}{dx^2}y(x)\right) + x(x^2-1)\left(\frac{d}{dx}y(x)\right) + (x^2+1)\,y(x) = 0$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $x^m \cdot y(x)$ to series expansion for $m = 0..2$

  $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- Shift index using $k- >k - m$

  $x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m = 1..3$

  $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$

- Shift index using $k- >k + 1 - m$

  $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$

- Convert $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

  $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(-1+r)^2\,x^r + a_1 r^2 x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(k+r-1)^2 + a_{k-2}(k+r-1)\right)x^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-1+r)^2 = 0$

- Values of r that satisfy the indicial equation

  $r = 1$

- Each term must be 0

  $a_1 r^2 = 0$

- Solve for the dependent coefficient(s)

  $a_1 = 0$

- Each term in the series must be 0, giving the recursion relation

  $(k+r-1)\,(a_k(k+r-1) + a_{k-2}) = 0$

- Shift index using $k- >k + 2$

  $(k+r+1)\,(a_{k+2}(k+r+1) + a_k) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{a_k}{k+r+1}$

- Recursion relation for $r = 1$
  $a_{k+2} = -\frac{a_k}{k+2}$
- Solution for $r = 1$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+1}, a_{k+2} = -\frac{a_k}{k+2}, a_1 = 0\right]$

2.1.140 Problem 142

Internal problem ID [9312]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 142
Date solved : `Monday, January 27, 2025 at 06:01:20 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2(x^2+1)\,y''-3x(-x^2+1)\,y'+4y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.320 (sec)

Writing the ode as

$$(x^4+x^2)\,y''+(3x^3-3x)\,y'+4y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^4+x^2\\ B &= 3x^3-3x\\ C &= 4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t}\\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{3x^4-10x^2-1}{4\,(x^3+x)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 3x^4-10x^2-1\\ t &= 4(x^3+x)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{3x^4-10x^2-1}{4\,(x^3+x)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.264: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 4 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^3 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = i$ of order 2. There is a pole at $x = -i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4x^2} + \frac{3}{4\,(x-i)^2} + \frac{3}{4\,(x+i)^2} + \frac{i}{4x-4i} - \frac{i}{4\,(x+i)}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

For the pole at $x = i$ let b be the coefficient of $\frac{1}{(x-i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

For the pole at $x=-i$ let b be the coefficient of $\frac{1}{(x+i)^2}$ in the partial fractions decomposition of r given above. Therefore $b=\frac{3}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0\\
\alpha_c^+ &= \frac{1}{2}+\sqrt{1+4b}=\frac{3}{2}\\
\alpha_c^- &= \frac{1}{2}-\sqrt{1+4b}=-\frac{1}{2}
\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty=0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r=\frac{s}{t}=\frac{3x^4-10x^2-1}{4\left(x^3+x\right)^2}$$

Since the $\gcd(s,t)=1$. This gives $b=\frac{3}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0\\
\alpha_\infty^+ &= \frac{1}{2}+\sqrt{1+4b}=\frac{3}{2}\\
\alpha_\infty^- &= \frac{1}{2}-\sqrt{1+4b}=-\frac{1}{2}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r=\frac{3x^4-10x^2-1}{4\left(x^3+x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$
i	2	0	$\frac{3}{2}$	$-\frac{1}{2}$
$-i$	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^-=-\frac{1}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^+ + \alpha_{c_2}^- + \alpha_{c_3}^-\right)\\
&= -\frac{1}{2}-\left(-\frac{1}{2}\right)\\
&= 0
\end{aligned}$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$\omega=\sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c+\frac{\alpha_c^{s(c)}}{x-c}\right)+s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$
\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{-}}{x-c_2}\right) + \left((-)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^{-}}{x-c_3}\right) + (-)[\sqrt{r}]_{\infty} \\
&= \frac{1}{2x} - \frac{1}{2(x-i)} - \frac{1}{2(x+i)} + (-)(0) \\
&= \frac{1}{2x} - \frac{1}{2(x-i)} - \frac{1}{2(x+i)} \\
&= \frac{1}{2x} - \frac{x}{x^2+1}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(0) + 2\left(\frac{1}{2x} - \frac{1}{2(x-i)} - \frac{1}{2(x+i)}\right)(0) + \left(\left(-\frac{1}{2x^2} + \frac{1}{2(x-i)^2} + \frac{1}{2(x+i)^2}\right) + \left(\frac{1}{2x} - \frac{1}{2(x-i)} - \frac{1}{2(x+
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx} \\
&= \mathrm{e}^{\int \left(\frac{1}{2x} - \frac{1}{2(x-i)} - \frac{1}{2(x+i)}\right) dx} \\
&= \frac{\sqrt{x}}{\sqrt{x^2+1}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{3x^3-3x}{x^4+x^2}\, dx} \\
&= z_1 e^{-\frac{3\ln(x^2+1)}{2} + \frac{3\ln(x)}{2}} \\
&= z_1 \left(\frac{x^{3/2}}{(x^2+1)^{3/2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{x^2}{(x^2+1)^2}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{3x^3-3x}{x^4+x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-3\ln(x^2+1)+3\ln(x)}}{(y_1)^2}\, dx \\
&= y_1 \left(\frac{x^2}{2} + \ln(x)\right)
\end{aligned}
$$

Therefore the solution is

$$\begin{aligned}y &= c_1 y_1 + c_2 y_2\\ &= c_1\left(\frac{x^2}{(x^2+1)^2}\right) + c_2\left(\frac{x^2}{(x^2+1)^2}\left(\frac{x^2}{2} + \ln(x)\right)\right)\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2(x^2+1)\left(\frac{d^2}{dx^2}y(x)\right) - 3x(-x^2+1)\left(\frac{d}{dx}y(x)\right) + 4y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{4y(x)}{x^2(x^2+1)} - \frac{3(x^2-1)\left(\frac{d}{dx}y(x)\right)}{x(x^2+1)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x) + \frac{3(x^2-1)\left(\frac{d}{dx}y(x)\right)}{x(x^2+1)} + \frac{4y(x)}{x^2(x^2+1)} = 0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

    $\left[P_2(x) = \frac{3(x^2-1)}{x(x^2+1)}, P_3(x) = \frac{4}{x^2(x^2+1)}\right]$

Solve

$$4x^2y'' + 2x^3y' + (3x^2+1)\, y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.236 (sec)

Writing the ode as

$$4x^2y'' + 2x^3y' + (3x^2+1)\, y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4x^2 \\ B &= 2x^3 \\ C &= 3x^2+1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^4 - 8x^2 - 4}{16x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^4 - 8x^2 - 4 \\ t &= 16x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^4 - 8x^2 - 4}{16x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.266: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 4 \\ &= -2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{x^2}{16} - \frac{1}{2} - \frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x}{4} - \frac{1}{x} - \frac{5}{2x^3} - \frac{10}{x^5} - \frac{105}{2x^7} - \frac{310}{x^9} - \frac{1965}{x^{11}} - \frac{13060}{x^{13}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{4}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= \frac{x}{4} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{x^2}{16}$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^4 - 8x^2 - 4}{16x^2} \\ &= Q + \frac{R}{16x^2} \\ &= \left(\frac{x^2}{16} - \frac{1}{2}\right) + \left(-\frac{1}{4x^2}\right) \\ &= \frac{x^2}{16} - \frac{1}{2} - \frac{1}{4x^2} \end{aligned}$$

We see that the coefficient of the term x in the quotient is $-\frac{1}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{1}{2}\right) - (0) \\ &= -\frac{1}{2} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{x}{4} \\ \alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{1}{2}}{\frac{1}{4}} - 1\right) &&= -\frac{3}{2} \\ \alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{1}{2}}{\frac{1}{4}} - 1\right) &&= \frac{1}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^4 - 8x^2 - 4}{16x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-2	$\frac{x}{4}$	$-\frac{3}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^+\right) \\ &= \frac{1}{2} - \left(\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{1}{2x} + (-)\left(\frac{x}{4}\right) \\ &= \frac{1}{2x} - \frac{x}{4} \\ &= \frac{1}{2x} - \frac{x}{4} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(\frac{1}{2x} - \frac{x}{4}\right)(0) + \left(\left(-\frac{1}{2x^2} - \frac{1}{4}\right) + \left(\frac{1}{2x} - \frac{x}{4}\right)^2 - \left(\frac{x^4 - 8x^2 - 4}{16x^2}\right)\right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= e^{\int \left(\frac{1}{2x} - \frac{x}{4}\right) dx} \\ &= \sqrt{x}\, e^{-\frac{x^2}{8}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{2x^3}{4x^2}\,dx} \\ &= z_1 e^{-\frac{x^2}{8}} \\ &= z_1\left(\mathrm{e}^{-\frac{x^2}{8}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-\frac{x^2}{4}}\sqrt{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{2x^3}{4x^2}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{-\frac{x^2}{4}}}{(y_1)^2}\,dx \\ &= y_1\left(-\frac{\mathrm{Ei}_1\left(-\frac{x^2}{4}\right)}{2}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\mathrm{e}^{-\frac{x^2}{4}}\sqrt{x}\right) + c_2\left(\mathrm{e}^{-\frac{x^2}{4}}\sqrt{x}\left(-\frac{\mathrm{Ei}_1\left(-\frac{x^2}{4}\right)}{2}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$4x^2\left(\frac{d^2}{dx^2}y(x)\right) + 2\left(\frac{d}{dx}y(x)\right)x^3 + (3x^2+1)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{(3x^2+1)y(x)}{4x^2} - \frac{x\left(\frac{d}{dx}y(x)\right)}{2}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x) + \frac{x\left(\frac{d}{dx}y(x)\right)}{2} + \frac{(3x^2+1)y(x)}{4x^2} = 0$

- ☐ Check to see if $x_0 = 0$ is a regular singular point
  - ○ Define functions

$\left[P_2(x) = \frac{x}{2}, P_3(x) = \frac{3x^2+1}{4x^2}\right]$

- $x \cdot P_2(x)$ is analytic at $x = 0$

  $\left(x \cdot P_2(x)\right)\bigg|_{x=0} = 0$

- $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = \frac{1}{4}$

- $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $4x^2\left(\frac{d^2}{dx^2}y(x)\right) + 2\left(\frac{d}{dx}y(x)\right)x^3 + (3x^2+1)\,y(x) = 0$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $x^m \cdot y(x)$ to series expansion for $m = 0..2$

  $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- Shift index using $k- >k - m$

  $x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- Convert $x^3 \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion

  $x^3 \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r+2}$

- Shift index using $k- >k - 2$

  $x^3 \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=2}^{\infty} a_{k-2}(k-2+r)\,x^{k+r}$

- Convert $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

  $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(-1+2r)^2 x^r + a_1(1+2r)^2 x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(2k+2r-1)^2 + a_{k-2}(2k+2r-1)\right) x^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-1+2r)^2 = 0$

- Values of r that satisfy the indicial equation

  $r = \frac{1}{2}$

- Each term must be 0

  $a_1(1+2r)^2 = 0$

- Solve for the dependent coefficient(s)

  $a_1 = 0$

- Each term in the series must be 0, giving the recursion relation

  $a_k(2k+2r-1)^2 + a_{k-2}(2k+2r-1) = 0$

- Shift index using $k- >k + 2$

  $a_{k+2}(2k+2r+3)^2 + a_k(2k+2r+3) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{a_k}{2k+2r+3}$

- Recursion relation for $r = \frac{1}{2}$

  $a_{k+2} = -\frac{a_k}{2k+4}$
- Solution for $r = \frac{1}{2}$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}, a_{k+2} = -\frac{a_k}{2k+4}, a_1 = 0\right]$

Solve

$$x^2\left(x^2+1\right) y''-x\left(-2x^2+1\right) y'+y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.241 (sec)

Writing the ode as

$$\left(x^4+x^2\right) y''+\left(2x^3-x\right) y'+y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^4+x^2 \\ B &= 2x^3-x \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{2x^2-1}{4\left(x^3+x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 2x^2-1 \\ t &= 4\left(x^3+x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{2x^2-1}{4\left(x^3+x\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.268: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 2 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^3 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = i$ of order 2. There is a pole at $x = -i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{3}{16\,(x-i)^2} - \frac{3}{16\,(x+i)^2} - \frac{5i}{16\,(x-i)} + \frac{5i}{16\,(x+i)} - \frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

For the pole at $x = i$ let b be the coefficient of $\frac{1}{(x-i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{4} \end{aligned}$$

For the pole at $x = -i$ let b be the coefficient of $\frac{1}{(x+i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{4} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{4}
\end{aligned}
$$

Since the order of r at ∞ is $4 > 2$ then

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= 0 \\
\alpha_\infty^- &= 1
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{2x^2 - 1}{4\left(x^3 + x\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$
i	2	0	$\frac{3}{4}$	$\frac{1}{4}$
$-i$	2	0	$\frac{3}{4}$	$\frac{1}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$ then

$$
\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^- + \alpha_{c_3}^-\right) \\
&= 1 - (1) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x - c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x - c_2} \right) + \left((-)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^-}{x - c_3} \right) + (-)[\sqrt{r}]_\infty \\
&= \frac{1}{2x} + \frac{1}{4x - 4i} + \frac{1}{4x + 4i} + (-)(0) \\
&= \frac{1}{2x} + \frac{1}{4x - 4i} + \frac{1}{4x + 4i} \\
&= \frac{1}{2x} + \frac{x}{2x^2 + 2}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{2x} + \frac{1}{4x-4i} + \frac{1}{4x+4i}\right)(0) + \left(\left(-\frac{1}{2x^2} - \frac{1}{4\,(x-i)^2} - \frac{1}{4\,(x+i)^2}\right) + \left(\frac{1}{2x} + \frac{1}{4x-4i} + \frac{1}{4x+4i}\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega\, dx} \\ &= e^{\int \left(\frac{1}{2x} + \frac{1}{4x-4i} + \frac{1}{4x+4i}\right) dx} \\ &= \sqrt{x}\,(x^2+1)^{1/4} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{2x^3-x}{x^4+x^2}\, dx} \\ &= z_1 e^{\frac{\ln(x)}{2} - \frac{3\ln(x^2+1)}{4}} \\ &= z_1 \left(\frac{\sqrt{x}}{(x^2+1)^{3/4}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{x}{\sqrt{x^2+1}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{2x^3-x}{x^4+x^2}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{\ln(x) - \frac{3\ln(x^2+1)}{2}}}{(y_1)^2}\, dx \\ &= y_1 \left(-\operatorname{arctanh}\left(\frac{1}{\sqrt{x^2+1}}\right)\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\frac{x}{\sqrt{x^2+1}}\right) + c_2\left(\frac{x}{\sqrt{x^2+1}}\left(-\operatorname{arctanh}\left(\frac{1}{\sqrt{x^2+1}}\right)\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2(x^2+1)\left(\frac{d^2}{dx^2}y(x)\right)-x(-2x^2+1)\left(\frac{d}{dx}y(x)\right)+y(x)=0$

- Highest derivative means the order of the ODE is 2

$\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

$\frac{d^2}{dx^2}y(x)=-\frac{y(x)}{x^2(x^2+1)}-\frac{(2x^2-1)\left(\frac{d}{dx}y(x)\right)}{x(x^2+1)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

$\frac{d^2}{dx^2}y(x)+\frac{(2x^2-1)\left(\frac{d}{dx}y(x)\right)}{x(x^2+1)}+\frac{y(x)}{x^2(x^2+1)}=0$

□ Check to see if x_0 is a regular singular point

- ◦ Define functions

$\left[P_2(x)=\frac{2x^2-1}{x(x^2+1)}, P_3(x)=\frac{1}{x^2(x^2+1)}\right]$

- ◦ $x\cdot P_2(x)$ is analytic at $x=0$

$(x\cdot P_2(x))\Big|_{x=0}=-1$

- ◦ $x^2\cdot P_3(x)$ is analytic at $x=0$

$(x^2\cdot P_3(x))\Big|_{x=0}=1$

- ◦ $x=0$is a regular singular point

Check to see if x_0 is a regular singular point

$x_0=0$

- Multiply by denominators

$x^2(x^2+1)\left(\frac{d^2}{dx^2}y(x)\right)+x(2x^2-1)\left(\frac{d}{dx}y(x)\right)+y(x)=0$

- Assume series solution for $y(x)$

$y(x)=\sum_{k=0}^{\infty}a_k x^{k+r}$

□ Rewrite ODE with series expansions

- ◦ Convert $x^m\cdot\left(\frac{d}{dx}y(x)\right)$ to series expansion for $m=1..3$

$x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,x^{k+r-1+m}$

- ◦ Shift index using $k->k+1-m$

$x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,x^{k+r}$

- ◦ Convert $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m=2..4$

$x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,x^{k+r-2+m}$

- ◦ Shift index using $k->k+2-m$

$x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=-2+m}^{\infty}a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$

Rewrite ODE with series expansions

$a_0(-1+r)^2x^r+a_1r^2x^{1+r}+\left(\sum_{k=2}^{\infty}\left(a_k(k+r-1)^2+a_{k-2}(k-2+r)\,(k+r-1)\right)x^{k+r}\right)=0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$(-1+r)^2=0$

- Values of r that satisfy the indicial equation

$r = 1$

- Each term must be 0

  $a_1 r^2 = 0$
- Solve for the dependent coefficient(s)

  $a_1 = 0$
- Each term in the series must be 0, giving the recursion relation

  $(k + r - 1)(a_k(k + r - 1) + a_{k-2}(k - 2 + r)) = 0$
- Shift index using $k- >k + 2$

  $(k + r + 1)(a_{k+2}(k + r + 1) + a_k(k + r)) = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{a_k(k+r)}{k+r+1}$
- Recursion relation for $r = 1$

  $a_{k+2} = -\frac{a_k(k+1)}{k+2}$
- Solution for $r = 1$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+1}, a_{k+2} = -\frac{a_k(k+1)}{k+2}, a_1 = 0\right]$

2.1.143 Problem 145

Internal problem ID [9315]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 145
Date solved : Monday, January 27, 2025 at 06:01:22 PM
CAS classification : [[_2nd_order, _with_linear_symmetries]]

Solve

$$2x^2\left(x^2+2\right)y''+7x^3y'+\left(3x^2+1\right)y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.303 (sec)

Writing the ode as

$$\left(2x^4+4x^2\right)y''+7x^3y'+\left(3x^2+1\right)y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=2x^4+4x^2\\B&=7x^3\\C&=3x^2+1\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned}r&=\frac{s}{t}\\&=\frac{2AB'-2BA'+B^2-4AC}{4A^2}\end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{-3x^4-16}{16\left(x^3+2x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned}s&=-3x^4-16\\t&=16\left(x^3+2x\right)^2\end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{-3x^4-16}{16\left(x^3+2x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.270: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 4 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16(x^3 + 2x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = i\sqrt{2}$ of order 2. There is a pole at $x = -i\sqrt{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{7}{64\left(x - i\sqrt{2}\right)^2} - \frac{7}{64\left(x + i\sqrt{2}\right)^2} - \frac{9i\sqrt{2}}{128\left(x - i\sqrt{2}\right)} + \frac{9i\sqrt{2}}{128\left(x + i\sqrt{2}\right)} - \frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2} \end{aligned}$$

For the pole at $x = i\sqrt{2}$ let b be the coefficient of $\frac{1}{\left(x-i\sqrt{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{7}{64}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{8} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{8}
\end{aligned}
$$

For the pole at $x = -i\sqrt{2}$ let b be the coefficient of $\frac{1}{\left(x+i\sqrt{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{7}{64}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{8} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{8}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = \frac{-3x^4 - 16}{16\,(x^3 + 2x)^2}
$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{3}{16}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{4} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{4}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{-3x^4 - 16}{16\,(x^3 + 2x)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$
$i\sqrt{2}$	2	0	$\frac{7}{8}$	$\frac{1}{8}$
$-i\sqrt{2}$	2	0	$\frac{7}{8}$	$\frac{1}{8}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{3}{4}$	$\frac{1}{4}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{3}{4}$ then

$$
\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^+ + \alpha_{c_2}^- + \alpha_{c_3}^-\right) \\
&= \frac{3}{4} - \left(\frac{3}{4}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x - c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x - c_2} \right) + \left((-)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^-}{x - c_3} \right) + (+)[\sqrt{r}]_\infty \\
&= \frac{1}{2x} + \frac{1}{8x - 8i\sqrt{2}} + \frac{1}{8x + 8i\sqrt{2}} + (0) \\
&= \frac{1}{2x} + \frac{1}{8x - 8i\sqrt{2}} + \frac{1}{8x + 8i\sqrt{2}} \\
&= \frac{1}{2x} + \frac{x}{4x^2 + 8}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{2x} + \frac{1}{8x - 8i\sqrt{2}} + \frac{1}{8x + 8i\sqrt{2}}\right)(0) + \left(\left(-\frac{1}{2x^2} - \frac{1}{8\left(x - i\sqrt{2}\right)^2} - \frac{1}{8\left(x + i\sqrt{2}\right)^2}\right) + \left(\frac{1}{2x} + \frac{}{8x}\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= e^{\int \left(\frac{1}{2x} + \frac{1}{8x - 8i\sqrt{2}} + \frac{1}{8x + 8i\sqrt{2}}\right) dx} \\
&= \left(x^2 + 2\right)^{1/8} \sqrt{x}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{7x^3}{2x^4 + 4x^2} \, dx} \\
&= z_1 e^{-\frac{7 \ln\left(x^2 + 2\right)}{8}} \\
&= z_1 \left(\frac{1}{\left(x^2 + 2\right)^{7/8}} \right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{\sqrt{x}}{\left(x^2 + 2\right)^{3/4}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{7x^3}{2x^4+4x^2} dx}}{(y_1)^2} dx \\
&= y_1 \int \frac{e^{-\frac{7\ln(x^2+2)}{4}}}{(y_1)^2} dx \\
&= y_1 \left(\int \frac{1}{(x^2+2)^{1/4} x} dx \right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{\sqrt{x}}{(x^2+2)^{3/4}} \right) + c_2 \left(\frac{\sqrt{x}}{(x^2+2)^{3/4}} \left(\int \frac{1}{(x^2+2)^{1/4} x} dx \right) \right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$2x^2(x^2+2)\left(\frac{d^2}{dx^2}y(x)\right) + 7\left(\frac{d}{dx}y(x)\right)x^3 + (3x^2+1)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$
- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{(3x^2+1)y(x)}{2(x^2+2)x^2} - \frac{7\left(\frac{d}{dx}y(x)\right)x}{2(x^2+2)}$
- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x) + \frac{7\left(\frac{d}{dx}y(x)\right)x}{2(x^2+2)} + \frac{(3x^2+1)y(x)}{2(x^2+2)x^2} = 0$

□ Check to see if x_0 is a regular singular point

  - Define functions

    $\left[P_2(x) = \frac{7x}{2(x^2+2)}, P_3(x) = \frac{3x^2+1}{2(x^2+2)x^2}\right]$
  - $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left.(x \cdot P_2(x))\right|_{x=0} = 0$
  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $\left.(x^2 \cdot P_3(x))\right|_{x=0} = \frac{1}{4}$
  - $x = 0$is a regular singular point

    Check to see if x_0 is a regular singular point

    $x_0 = 0$

- Multiply by denominators

  $2x^2(x^2+2)\left(\frac{d^2}{dx^2}y(x)\right) + 7\left(\frac{d}{dx}y(x)\right)x^3 + (3x^2+1)\,y(x) = 0$
- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

  - Convert $x^m \cdot y(x)$ to series expansion for $m = 0..2$

$x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- Shift index using $k- >k-m$

  $x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- Convert $x^3 \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion

  $x^3 \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r+2}$

- Shift index using $k- >k-2$

  $x^3 \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=2}^{\infty} a_{k-2}(k-2+r)\, x^{k+r}$

- Convert $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m = 2..4$

  $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-2+m}$

- Shift index using $k- >k+2-m$

  $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(-1+2r)^2\, x^r + a_1(1+2r)^2\, x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(2k+2r-1)^2 + a_{k-2}(2k+2r-1)\,(k+r-1)\right) x\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-1+2r)^2 = 0$

- Values of r that satisfy the indicial equation

  $r = \frac{1}{2}$

- Each term must be 0

  $a_1(1+2r)^2 = 0$

- Solve for the dependent coefficient(s)

  $a_1 = 0$

- Each term in the series must be 0, giving the recursion relation

  $4\left(k+r-\frac{1}{2}\right)\left(\frac{a_{k-2}(k+r-1)}{2} + \left(k+r-\frac{1}{2}\right) a_k\right) = 0$

- Shift index using $k- >k+2$

  $4\left(k+\frac{3}{2}+r\right)\left(\frac{a_k(k+r+1)}{2} + \left(k+\frac{3}{2}+r\right) a_{k+2}\right) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{a_k(k+r+1)}{2k+2r+3}$

- Recursion relation for $r = \frac{1}{2}$

  $a_{k+2} = -\frac{a_k\left(k+\frac{3}{2}\right)}{2k+4}$

- Solution for $r = \frac{1}{2}$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}, a_{k+2} = -\frac{a_k\left(k+\frac{3}{2}\right)}{2k+4}, a_1 = 0\right]$

2.1.144 Problem 146

Internal problem ID [9316]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 146
Date solved : `Monday, January 27, 2025 at 06:01:23 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2\left(x^2+1\right)y''-x\left(-4x^2+1\right)y'+\left(2x^2+1\right)y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.277 (sec)

Writing the ode as

$$\left(x^4+x^2\right)y''+\left(4x^3-x\right)y'+\left(2x^2+1\right)y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^4+x^2 \\ B &= 4x^3-x \\ C &= 2x^2+1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{-6x^2-1}{4\left(x^3+x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -6x^2-1 \\ t &= 4\left(x^3+x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{-6x^2-1}{4\left(x^3+x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\,e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.272: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 2 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^3+x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = i$ of order 2. There is a pole at $x = -i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{5}{16\,(x-i)^2} + \frac{5}{16\,(x+i)^2} + \frac{3i}{16\,(x-i)} - \frac{3i}{16\,(x+i)} - \frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

For the pole at $x = i$ let b be the coefficient of $\frac{1}{(x-i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{5}{16}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{4} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{4} \end{aligned}$$

For the pole at $x=-i$ let b be the coefficient of $\frac{1}{(x+i)^2}$ in the partial fractions decomposition of r given above. Therefore $b=\frac{5}{16}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= \frac{1}{2}+\sqrt{1+4b}=\frac{5}{4}\\ \alpha_c^- &= \frac{1}{2}-\sqrt{1+4b}=-\frac{1}{4}\end{aligned}$$

Since the order of r at ∞ is $4>2$ then

$$\begin{aligned}[\sqrt{r}]_\infty &= 0\\ \alpha_\infty^+ &= 0\\ \alpha_\infty^- &= 1\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r=\frac{-6x^2-1}{4\left(x^3+x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$
i	2	0	$\frac{5}{4}$	$-\frac{1}{4}$
$-i$	2	0	$\frac{5}{4}$	$-\frac{1}{4}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+=0$ then

$$\begin{aligned}d &= \alpha_\infty^+-\left(\alpha_{c_1}^++\alpha_{c_2}^-+\alpha_{c_3}^-\right)\\ &= 0-(0)\\ &= 0\end{aligned}$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$\omega=\sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c+\frac{\alpha_c^{s(c)}}{x-c}\right)+s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}\omega &= \left((+)[\sqrt{r}]_{c_1}+\frac{\alpha_{c_1}^+}{x-c_1}\right)+\left((-)[\sqrt{r}]_{c_2}+\frac{\alpha_{c_2}^-}{x-c_2}\right)+\left((-)[\sqrt{r}]_{c_3}+\frac{\alpha_{c_3}^-}{x-c_3}\right)+(+)[\sqrt{r}]_\infty\\ &= \frac{1}{2x}-\frac{1}{4\left(x-i\right)}-\frac{1}{4\left(x+i\right)}+(0)\\ &= \frac{1}{2x}-\frac{1}{4\left(x-i\right)}-\frac{1}{4\left(x+i\right)}\\ &= \frac{1}{2x^3+2x}\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{2x} - \frac{1}{4(x-i)} - \frac{1}{4(x+i)}\right)(0) + \left(\left(-\frac{1}{2x^2} + \frac{1}{4(x-i)^2} + \frac{1}{4(x+i)^2}\right) + \left(\frac{1}{2x} - \frac{1}{4(x-i)} - \frac{1}{4(x+\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= e^{\int \left(\frac{1}{2x} - \frac{1}{4(x-i)} - \frac{1}{4(x+i)}\right) dx} \\ &= \frac{\sqrt{x}}{\left(x^2+1\right)^{1/4}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2} \frac{4x^3 - x}{x^4 + x^2} \, dx} \\ &= z_1 e^{-\frac{5\ln\left(x^2+1\right)}{4} + \frac{\ln(x)}{2}} \\ &= z_1 \left(\frac{\sqrt{x}}{\left(x^2+1\right)^{5/4}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{x}{\left(x^2+1\right)^{3/2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{4x^3 - x}{x^4 + x^2} \, dx}}{\left(y_1\right)^2} \, dx \\ &= y_1 \int \frac{e^{-\frac{5\ln\left(x^2+1\right)}{2} + \ln(x)}}{\left(y_1\right)^2} \, dx \\ &= y_1 \left(\sqrt{x^2+1} - \operatorname{arctanh}\left(\frac{1}{\sqrt{x^2+1}}\right)\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\frac{x}{\left(x^2+1\right)^{3/2}}\right) + c_2 \left(\frac{x}{\left(x^2+1\right)^{3/2}} \left(\sqrt{x^2+1} - \operatorname{arctanh}\left(\frac{1}{\sqrt{x^2+1}}\right)\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2(x^2+1)\left(\frac{d^2}{dx^2}y(x)\right) - x(-4x^2+1)\left(\frac{d}{dx}y(x)\right) + (2x^2+1)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{(2x^2+1)y(x)}{x^2(x^2+1)} - \frac{(4x^2-1)\left(\frac{d}{dx}y(x)\right)}{x(x^2+1)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x) + \frac{(4x^2-1)\left(\frac{d}{dx}y(x)\right)}{x(x^2+1)} + \frac{(2x^2+1)y(x)}{x^2(x^2+1)} = 0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

  $\left[P_2(x) = \frac{4x^2-1}{x(x^2+1)}, P_3(x) = \frac{2x^2+1}{x^2(x^2+1)}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

  $\left(x \cdot P_2(x)\right)\bigg|_{x=0} = -1$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = 1$

  ◦ $x = 0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $x^2(x^2+1)\left(\frac{d^2}{dx^2}y(x)\right) + x(4x^2-1)\left(\frac{d}{dx}y(x)\right) + (2x^2+1)\,y(x) = 0$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $x^m \cdot y(x)$ to series expansion for $m = 0..2$

  $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

  ◦ Shift index using $k- >k-m$

  $x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

  ◦ Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m = 1..3$

  $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1+m}$

  ◦ Shift index using $k- >k+1-m$

  $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$

  ◦ Convert $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m = 2..4$

  $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-2+m}$

  ◦ Shift index using $k- >k+2-m$

  $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, x^{k+r}$

  Rewrite ODE with series expansions

$$a_0(-1+r)^2 x^r + a_1 r^2 x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(k+r-1)^2 + a_{k-2}(k+r)(k+r-1)\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $(-1+r)^2 = 0$
- Values of r that satisfy the indicial equation
  $r = 1$
- Each term must be 0
  $a_1 r^2 = 0$
- Solve for the dependent coefficient(s)
  $a_1 = 0$
- Each term in the series must be 0, giving the recursion relation
  $(k+r-1)\left(a_k(k+r-1) + a_{k-2}(k+r)\right) = 0$
- Shift index using $k->k+2$
  $(k+r+1)\left(a_{k+2}(k+r+1) + a_k(k+r+2)\right) = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+2} = -\frac{a_k(k+r+2)}{k+r+1}$
- Recursion relation for $r = 1$
  $a_{k+2} = -\frac{a_k(k+3)}{k+2}$
- Solution for $r = 1$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+1}, a_{k+2} = -\frac{a_k(k+3)}{k+2}, a_1 = 0\right]$

2.1.145 Problem 147

Internal problem ID [9317]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 147
Date solved : `Monday, January 27, 2025 at 06:01:24 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$4x^2\left(x^2+4\right)y''+3x\left(3x^2+8\right)y'+\left(-9x^2+1\right)y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.327 (sec)

Writing the ode as

$$\left(4x^4+16x^2\right)y''+\left(9x^3+24x\right)y'+\left(-9x^2+1\right)y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4x^4+16x^2 \\ B &= 9x^3+24x \\ C &= -9x^2+1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{153x^4+704x^2-256}{64\left(x^3+4x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 153x^4+704x^2-256 \\ t &= 64\left(x^3+4x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{153x^4+704x^2-256}{64\left(x^3+4x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.274: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 4 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 64(x^3+4x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = 2i$ of order 2. There is a pole at $x = -2i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{39}{256\,(x-2i)^2} - \frac{39}{256\,(x+2i)^2} - \frac{377i}{512\,(x-2i)} + \frac{377i}{512\,(x+2i)} - \frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

For the pole at $x = 2i$ let b be the coefficient of $\frac{1}{(x-2i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{39}{256}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{13}{16} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{3}{16} \end{aligned}$$

For the pole at $x = -2i$ let b be the coefficient of $\frac{1}{(x+2i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{39}{256}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0\\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{13}{16}\\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{3}{16}
\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{153x^4 + 704x^2 - 256}{64\,(x^3+4x)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{153}{64}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0\\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{17}{8}\\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{9}{8}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{153x^4 + 704x^2 - 256}{64\,(x^3+4x)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$
$2i$	2	0	$\frac{13}{16}$	$\frac{3}{16}$
$-2i$	2	0	$\frac{13}{16}$	$\frac{3}{16}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{17}{8}$	$-\frac{9}{8}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{17}{8}$ then

$$\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^+ + \alpha_{c_2}^+ + \alpha_{c_3}^+\right)\\
&= \frac{17}{8} - \left(\frac{17}{8}\right)\\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x-c_1}\right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{+}}{x-c_2}\right) + \left((+)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^{+}}{x-c_3}\right) + (+)[\sqrt{r}]_{\infty} \\
&= \frac{1}{2x} + \frac{13}{16\,(x-2i)} + \frac{13}{16\,(x+2i)} + (0) \\
&= \frac{1}{2x} + \frac{13}{16\,(x-2i)} + \frac{13}{16\,(x+2i)} \\
&= \frac{1}{2x} + \frac{13x}{8x^2+32}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{2x} + \frac{13}{16\,(x-2i)} + \frac{13}{16\,(x+2i)}\right)(0) + \left(\left(-\frac{1}{2x^2} - \frac{13}{16\,(x-2i)^2} - \frac{13}{16\,(x+2i)^2}\right) + \left(\frac{1}{2x} + \frac{1}{16\,(x}\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx} \\
&= \mathrm{e}^{\int \left(\frac{1}{2x} + \frac{13}{16(x-2i)} + \frac{13}{16(x+2i)}\right) dx} \\
&= \left(x^2+4\right)^{13/16} \sqrt{x}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{9x^3+24x}{4x^4+16x^2}\, dx} \\
&= z_1 e^{-\frac{3\ln(x)}{4} - \frac{3\ln\left(x^2+4\right)}{16}} \\
&= z_1 \left(\frac{1}{x^{3/4}\left(x^2+4\right)^{3/16}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{\left(x^2+4\right)^{5/8}}{x^{1/4}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{9x^3+24x}{4x^4+16x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{\mathrm{e}^{-\frac{3\ln(x)}{2} - \frac{3\ln\left(x^2+4\right)}{8}}}{(y_1)^2}\, dx \\
&= y_1 \left(\int \frac{\mathrm{e}^{-\frac{3\ln(x)}{2} - \frac{3\ln\left(x^2+4\right)}{8}}\sqrt{x}}{\left(x^2+4\right)^{5/4}} dx\right)
\end{aligned}$$

Therefore the solution is

$$y = c_1 y_1 + c_2 y_2$$
$$= c_1 \left(\frac{(x^2+4)^{5/8}}{x^{1/4}}\right) + c_2 \left(\frac{(x^2+4)^{5/8}}{x^{1/4}} \left(\int \frac{e^{-\frac{3\ln(x)}{2} - \frac{3\ln(x^2+4)}{8}} \sqrt{x}}{(x^2+4)^{5/4}} dx\right)\right)$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve
$4x^2(x^2+4)\left(\frac{d^2}{dx^2}y(x)\right) + 3x(3x^2+8)\left(\frac{d}{dx}y(x)\right) + (-9x^2+1)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2
  $\frac{d^2}{dx^2}y(x)$
- Isolate 2nd derivative
  $\frac{d^2}{dx^2}y(x) = \frac{(9x^2-1)y(x)}{4x^2(x^2+4)} - \frac{3(3x^2+8)\left(\frac{d}{dx}y(x)\right)}{4x(x^2+4)}$
- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea
  $\frac{d^2}{dx^2}y(x) + \frac{3(3x^2+8)\left(\frac{d}{dx}y(x)\right)}{4x(x^2+4)} - \frac{(9x^2-1)y(x)}{4x^2(x^2+4)} = 0$

□ Check to see if x_0 is a regular singular point
  - Define functions
    $\left[P_2(x) = \frac{3(3x^2+8)}{4x(x^2+4)}, P_3(x) = -\frac{9x^2-1}{4x^2(x^2+4)}\right]$
  - $x \cdot P_2(x)$ is analytic at $x = 0$
    $(x \cdot P_2(x))\bigg|_{x=0} = \frac{3}{2}$
  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$
    $(x^2 \cdot P_3(x))\bigg|_{x=0} = \frac{1}{16}$
  - $x = 0$is a regular singular point
    Check to see if x_0 is a regular singular point
    $x_0 = 0$
- Multiply by denominators
  $4x^2(x^2+4)\left(\frac{d^2}{dx^2}y(x)\right) + 3x(3x^2+8)\left(\frac{d}{dx}y(x)\right) + (-9x^2+1)\,y(x) = 0$
- Assume series solution for $y(x)$
  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions
  - Convert $x^m \cdot y(x)$ to series expansion for $m = 0..2$
    $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$
  - Shift index using $k- >k-m$
    $x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$
  - Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m = 1..3$
    $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$
  - Shift index using $k- >k+1-m$

$$x^m \cdot \left(\frac{d}{dx} y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$$

- ◦ Convert $x^m \cdot \left(\frac{d^2}{dx^2} y(x)\right)$ to series expansion for $m = 2..4$

$$x^m \cdot \left(\frac{d^2}{dx^2} y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-2+m}$$

- ◦ Shift index using $k- >k+2-m$

$$x^m \cdot \left(\frac{d^2}{dx^2} y(x)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0(1+4r)^2\, x^r + a_1(5+4r)^2\, x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(4k+4r+1)^2 + a_{k-2}(4k+4r+1)\,(k-3+r)\right) x^{k+}\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$(1+4r)^2 = 0$$

- Values of r that satisfy the indicial equation

$$r = -\frac{1}{4}$$

- Each term must be 0

$$a_1(5+4r)^2 = 0$$

- Solve for the dependent coefficient(s)

$$a_1 = 0$$

- Each term in the series must be 0, giving the recursion relation

$$16\left(\frac{a_{k-2}(k-3+r)}{4} + a_k\left(k+r+\frac{1}{4}\right)\right)\left(k+r+\frac{1}{4}\right) = 0$$

- Shift index using $k- >k+2$

$$16\left(\frac{a_k(k+r-1)}{4} + a_{k+2}\left(k+\frac{9}{4}+r\right)\right)\left(k+\frac{9}{4}+r\right) = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+2} = -\frac{a_k(k+r-1)}{4k+4r+9}$$

- Recursion relation for $r = -\frac{1}{4}$

$$a_{k+2} = -\frac{a_k\left(k-\frac{5}{4}\right)}{4k+8}$$

- Solution for $r = -\frac{1}{4}$

$$\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k-\frac{1}{4}}, a_{k+2} = -\frac{a_k\left(k-\frac{5}{4}\right)}{4k+8}, a_1 = 0\right]$$

2.1.146 Problem 148

Internal problem ID [9318]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 148
Date solved : `Monday, January 27, 2025 at 06:01:24 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$3x^2\left(x^2+3\right)y''+x\left(11x^2+3\right)y'+\left(5x^2+1\right)y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.318 (sec)

Writing the ode as

$$\left(3x^4+9x^2\right)y''+\left(11x^3+3x\right)y'+\left(5x^2+1\right)y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A&=3x^4+9x^2\\ B&=11x^3+3x\\ C&=5x^2+1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r&=\frac{s}{t}\\ &=\frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{-5x^4+18x^2-81}{36\left(x^3+3x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s&=-5x^4+18x^2-81\\ t&=36\left(x^3+3x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{-5x^4+18x^2-81}{36\left(x^3+3x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.276: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 4 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 36(x^3 + 3x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = i\sqrt{3}$ of order 2. There is a pole at $x = -i\sqrt{3}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4x^2} - \frac{5}{36\left(x - i\sqrt{3}\right)^2} - \frac{5}{36\left(x + i\sqrt{3}\right)^2} - \frac{7i\sqrt{3}}{108\left(x - i\sqrt{3}\right)} + \frac{7i\sqrt{3}}{108\left(x + i\sqrt{3}\right)}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2} \end{aligned}$$

For the pole at $x = i\sqrt{3}$ let b be the coefficient of $\frac{1}{\left(x-i\sqrt{3}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{5}{36}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0\\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{6}\\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{6}
\end{aligned}$$

For the pole at $x = -i\sqrt{3}$ let b be the coefficient of $\frac{1}{\left(x+i\sqrt{3}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{5}{36}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0\\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{6}\\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{6}
\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{-5x^4 + 18x^2 - 81}{36\left(x^3 + 3x\right)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{5}{36}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0\\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{6}\\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{6}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{-5x^4 + 18x^2 - 81}{36\left(x^3 + 3x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$
$i\sqrt{3}$	2	0	$\frac{5}{6}$	$\frac{1}{6}$
$-i\sqrt{3}$	2	0	$\frac{5}{6}$	$\frac{1}{6}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{5}{6}$	$\frac{1}{6}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{5}{6}$ then

$$\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^+ + \alpha_{c_2}^- + \alpha_{c_3}^-\right)\\
&= \frac{5}{6} - \left(\frac{5}{6}\right)\\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{-}}{x-c_2}\right) + \left((-)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^{-}}{x-c_3}\right) + (+)[\sqrt{r}]_\infty \\
&= \frac{1}{2x} + \frac{1}{6x-6i\sqrt{3}} + \frac{1}{6x+6i\sqrt{3}} + (0) \\
&= \frac{1}{2x} + \frac{1}{6x-6i\sqrt{3}} + \frac{1}{6x+6i\sqrt{3}} \\
&= \frac{1}{2x} + \frac{x}{3x^2+9}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{2x} + \frac{1}{6x-6i\sqrt{3}} + \frac{1}{6x+6i\sqrt{3}}\right)(0) + \left(\left(-\frac{1}{2x^2} - \frac{1}{6\left(x-i\sqrt{3}\right)^2} - \frac{1}{6\left(x+i\sqrt{3}\right)^2}\right) + \left(\frac{1}{2x} + \frac{1}{6x-\cdots}\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx} \\
&= e^{\int \left(\frac{1}{2x} + \frac{1}{6x-6i\sqrt{3}} + \frac{1}{6x+6i\sqrt{3}}\right)dx} \\
&= \sqrt{x}\left(x^2+3\right)^{1/6}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{11x^3+3x}{3x^4+9x^2}\, dx} \\
&= z_1 e^{-\frac{\ln(x)}{6} - \frac{5\ln\left(x^2+3\right)}{6}} \\
&= z_1\left(\frac{1}{x^{1/6}\left(x^2+3\right)^{5/6}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{x^{1/3}}{\left(x^2+3\right)^{2/3}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{11x^3+3x}{3x^4+9x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{\ln(x)}{3}-\frac{5\ln(x^2+3)}{3}}}{(y_1)^2}\,dx \\
&= y_1 \left(\int \frac{\mathrm{e}^{-\frac{\ln(x)}{3}-\frac{5\ln(x^2+3)}{3}}(x^2+3)^{4/3}}{x^{2/3}}dx\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\

Maple step by step solution

Let's solve

$3x^2(x^2+3)\left(\frac{d^2}{dx^2}y(x)\right) + x(11x^2+3)\left(\frac{d}{dx}y(x)\right) + (5x^2+1)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{(5x^2+1)y(x)}{3x^2(x^2+3)} - \frac{(11x^2+3)\left(\frac{d}{dx}y(x)\right)}{3x(x^2+3)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x) + \frac{(11x^2+3)\left(\frac{d}{dx}y(x)\right)}{3x(x^2+3)} + \frac{(5x^2+1)y(x)}{3x^2(x^2+3)} = 0$

☐ Check to see if x_0 is a regular singular point

  ◦ Define functions

  $\left[P_2(x) = \frac{11x^2+3}{3x(x^2+3)}, P_3(x) = \frac{5x^2+1}{3x^2(x^2+3)}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

  $(x \cdot P_2(x))\Big|_{x=0} = \frac{1}{3}$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $(x^2 \cdot P_3(x))\Big|_{x=0} = \frac{1}{9}$

  ◦ $x = 0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $3x^2(x^2+3)\left(\frac{d^2}{dx^2}y(x)\right) + x(11x^2+3)\left(\frac{d}{dx}y(x)\right) + (5x^2+1)\,y(x) = 0$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $x^m \cdot y(x)$ to series expansion for $m = 0..2$

  $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$
- Shift index using $k- >k - m$

  $x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$
- Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m = 1..3$

  $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1+m}$
- Shift index using $k- >k + 1 - m$

  $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$
- Convert $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m = 2..4$

  $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-2+m}$
- Shift index using $k- >k + 2 - m$

  $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(-1+3r)^2 x^r + a_1(2+3r)^2 x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(3k+3r-1)^2 + a_{k-2}(3k+3r-1)\,(k+r-1)\right) x^{k+r}\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-1+3r)^2 = 0$
- Values of r that satisfy the indicial equation

  $r = \frac{1}{3}$
- Each term must be 0

  $a_1(2+3r)^2 = 0$
- Solve for the dependent coefficient(s)

  $a_1 = 0$
- Each term in the series must be 0, giving the recursion relation

  $9\left(\frac{a_{k-2}(k+r-1)}{3} + \left(k - \frac{1}{3} + r\right) a_k\right)\left(k - \frac{1}{3} + r\right) = 0$
- Shift index using $k- >k + 2$

  $9\left(\frac{a_k(k+r+1)}{3} + \left(k + \frac{5}{3} + r\right) a_{k+2}\right)\left(k + \frac{5}{3} + r\right) = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{a_k(k+r+1)}{3k+3r+5}$
- Recursion relation for $r = \frac{1}{3}$

  $a_{k+2} = -\frac{a_k\left(k+\frac{4}{3}\right)}{3k+6}$
- Solution for $r = \frac{1}{3}$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{3}}, a_{k+2} = -\frac{a_k\left(k+\frac{4}{3}\right)}{3k+6}, a_1 = 0\right]$

2.1.147 Problem 149

Internal problem ID [9319]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 149
Date solved : `Monday, January 27, 2025 at 06:01:25 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$9x^2y'' - 3x(-2x^2+7)\,y' + (2x^2+25)\,y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.274 (sec)

Writing the ode as

$$9x^2y'' + (6x^3-21x)\,y' + (2x^2+25)\,y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 9x^2 \\ B &= 6x^3 - 21x \\ C &= 2x^2 + 25 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{4x^4 - 24x^2 - 9}{36x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 4x^4 - 24x^2 - 9 \\ t &= 36x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{4x^4 - 24x^2 - 9}{36x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.278: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 4 \\ &= -2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 36x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{x^2}{9} - \frac{2}{3} - \frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x}{3} - \frac{1}{x} - \frac{15}{8x^3} - \frac{45}{8x^5} - \frac{2835}{128x^7} - \frac{12555}{128x^9} - \frac{477495}{1024x^{11}} - \frac{2380185}{1024x^{13}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{3}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= \frac{x}{3} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{x^2}{9}$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{4x^4 - 24x^2 - 9}{36x^2} \\ &= Q + \frac{R}{36x^2} \\ &= \left(\frac{x^2}{9} - \frac{2}{3}\right) + \left(-\frac{1}{4x^2}\right) \\ &= \frac{x^2}{9} - \frac{2}{3} - \frac{1}{4x^2} \end{aligned}$$

We see that the coefficient of the term x in the quotient is $-\frac{2}{3}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{2}{3}\right) - (0) \\ &= -\frac{2}{3} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{x}{3} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{2}{3}}{\frac{1}{3}} - 1\right) &&= -\frac{3}{2} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{2}{3}}{\frac{1}{3}} - 1\right) &&= \frac{1}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{4x^4 - 24x^2 - 9}{36x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-2	$\frac{x}{3}$	$-\frac{3}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^- - (\alpha_{c_1}^+) \\
&= \frac{1}{2} - \left(\frac{1}{2}\right) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x - c_1} \right) + (-)[\sqrt{r}]_\infty \\
&= \frac{1}{2x} + (-)\left(\frac{x}{3}\right) \\
&= \frac{1}{2x} - \frac{x}{3} \\
&= \frac{1}{2x} - \frac{x}{3}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned}
(0) + 2\left(\frac{1}{2x} - \frac{x}{3}\right)(0) + \left(\left(-\frac{1}{2x^2} - \frac{1}{3}\right) + \left(\frac{1}{2x} - \frac{x}{3}\right)^2 - \left(\frac{4x^4 - 24x^2 - 9}{36x^2}\right)\right) &= 0 \\
0 &= 0
\end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= e^{\int \left(\frac{1}{2x} - \frac{x}{3}\right) dx} \\
&= \sqrt{x}\, e^{-\frac{x^2}{6}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{6x^3-21x}{9x^2}\,dx} \\
&= z_1 e^{-\frac{x^2}{6}+\frac{7\ln(x)}{6}} \\
&= z_1 \left(x^{7/6} \mathrm{e}^{-\frac{x^2}{6}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = x^{5/3} \mathrm{e}^{-\frac{x^2}{3}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{6x^3-21x}{9x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{x^2}{3}+\frac{7\ln(x)}{3}}}{(y_1)^2}\,dx \\
&= y_1 \left(-\frac{\mathrm{Ei}_1\left(-\frac{x^2}{3}\right)}{2}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(x^{5/3} \mathrm{e}^{-\frac{x^2}{3}}\right) + c_2 \left(x^{5/3} \mathrm{e}^{-\frac{x^2}{3}} \left(-\frac{\mathrm{Ei}_1\left(-\frac{x^2}{3}\right)}{2}\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$9x^2 \left(\frac{d^2}{dx^2} y(x)\right) - 3x(-2x^2+7)\left(\frac{d}{dx} y(x)\right) + (2x^2+25)\, y(x) = 0$

2.1.148 Problem 150

Internal problem ID [9320]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 150
Date solved : `Monday, January 27, 2025 at 06:01:26 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2y'' - x\left(-x^2+1\right)y' + \left(x^2+1\right)y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.243 (sec)

Writing the ode as

$$x^2y'' + \left(x^3-x\right)y' + \left(x^2+1\right)y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= x^3 - x \\ C &= x^2 + 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^4 - 4x^2 - 1}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^4 - 4x^2 - 1 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^4 - 4x^2 - 1}{4x^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.280: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 4 \\ &= -2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{x^2}{4} - 1 - \frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x}{2} - \frac{1}{x} - \frac{5}{4x^3} - \frac{5}{2x^5} - \frac{105}{16x^7} - \frac{155}{8x^9} - \frac{1965}{32x^{11}} - \frac{3265}{16x^{13}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= \frac{x}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{x^2}{4}$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^4 - 4x^2 - 1}{4x^2} \\ &= Q + \frac{R}{4x^2} \\ &= \left(\frac{x^2}{4} - 1\right) + \left(-\frac{1}{4x^2}\right) \\ &= \frac{x^2}{4} - 1 - \frac{1}{4x^2} \end{aligned}$$

We see that the coefficient of the term x in the quotient is -1. Now b can be found.

$$\begin{aligned} b &= (-1) - (0) \\ &= -1 \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{x}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-1}{\frac{1}{2}} - 1\right) &&= -\frac{3}{2} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-1}{\frac{1}{2}} - 1\right) &&= \frac{1}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^4 - 4x^2 - 1}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-2	$\frac{x}{2}$	$-\frac{3}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^+\right) \\ &= \frac{1}{2} - \left(\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{1}{2x} + (-)\left(\frac{x}{2}\right) \\ &= \frac{1}{2x} - \frac{x}{2} \\ &= \frac{1}{2x} - \frac{x}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(\frac{1}{2x} - \frac{x}{2}\right)(0) + \left(\left(-\frac{1}{2x^2} - \frac{1}{2}\right) + \left(\frac{1}{2x} - \frac{x}{2}\right)^2 - \left(\frac{x^4 - 4x^2 - 1}{4x^2}\right)\right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= e^{\int \left(\frac{1}{2x} - \frac{x}{2}\right) dx} \\ &= \sqrt{x}\, e^{-\frac{x^2}{4}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{x^3-x}{x^2}\,dx} \\ &= z_1 e^{-\frac{x^2}{4}+\frac{\ln(x)}{2}} \\ &= z_1\left(\sqrt{x}\,\mathrm{e}^{-\frac{x^2}{4}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = x\,\mathrm{e}^{-\frac{x^2}{2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{x^3-x}{x^2}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{-\frac{x^2}{2}+\ln(x)}}{(y_1)^2}\,dx \\ &= y_1\left(-\frac{\mathrm{Ei}_1\left(-\frac{x^2}{2}\right)}{2}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(x\,\mathrm{e}^{-\frac{x^2}{2}}\right) + c_2\left(x\,\mathrm{e}^{-\frac{x^2}{2}}\left(-\frac{\mathrm{Ei}_1\left(-\frac{x^2}{2}\right)}{2}\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2\left(\frac{d^2}{dx^2}y(x)\right) - x(-x^2+1)\left(\frac{d}{dx}y(x)\right) + (x^2+1)\,y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$
- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{(x^2+1)y(x)}{x^2} - \frac{(x^2-1)\left(\frac{d}{dx}y(x)\right)}{x}$
- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x) + \frac{(x^2-1)\left(\frac{d}{dx}y(x)\right)}{x} + \frac{(x^2+1)y(x)}{x^2} = 0$

☐ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

$\left[P_2(x) = \frac{x^2-1}{x}, P_3(x) = \frac{x^2+1}{x^2}\right]$

- ∘ $x \cdot P_2(x)$ is analytic at $x = 0$

  $\left(x \cdot P_2(x)\right)\Big|_{x=0} = -1$

- ∘ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $\left(x^2 \cdot P_3(x)\right)\Big|_{x=0} = 1$

- ∘ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $x^2\left(\frac{d^2}{dx^2}y(x)\right) + x(x^2-1)\left(\frac{d}{dx}y(x)\right) + (x^2+1)\, y(x) = 0$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

- ∘ Convert $x^m \cdot y(x)$ to series expansion for $m = 0..2$

  $x^m \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- ∘ Shift index using $k- >k - m$

  $x^m \cdot y(x) = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- ∘ Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m = 1..3$

  $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1+m}$

- ∘ Shift index using $k- >k + 1 - m$

  $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$

- ∘ Convert $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

  $x^2 \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(-1+r)^2\, x^r + a_1 r^2 x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(k+r-1)^2 + a_{k-2}(k+r-1)\right) x^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-1+r)^2 = 0$

- Values of r that satisfy the indicial equation

  $r = 1$

- Each term must be 0

  $a_1 r^2 = 0$

- Solve for the dependent coefficient(s)

  $a_1 = 0$

- Each term in the series must be 0, giving the recursion relation

  $(k+r-1)\,(a_k(k+r-1) + a_{k-2}) = 0$

- Shift index using $k- >k + 2$

  $(k+r+1)\,(a_{k+2}(k+r+1) + a_k) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{a_k}{k+r+1}$

- Recursion relation for $r = 1$
  $a_{k+2} = -\frac{a_k}{k+2}$
- Solution for $r = 1$
  $$\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+1}, a_{k+2} = -\frac{a_k}{k+2}, a_1 = 0\right]$$

2.1.149 Problem 151

Internal problem ID [9321]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 151
Date solved : `Monday, January 27, 2025 at 06:01:26 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2(1-2x)\,y''+3xy'+(1+4x)\,y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.221 (sec)

Writing the ode as

$$\left(-2x^3+x^2\right)y''+3xy'+(1+4x)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= -2x^3+x^2 \\ B &= 3x \\ C &= 1+4x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{32x^2+16x-1}{4\left(2x^2-x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 32x^2+16x-1 \\ t &= 4\left(2x^2-x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{32x^2+16x-1}{4\left(2x^2-x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.282: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(2x^2 - x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = \frac{1}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{3}{x} - \frac{1}{4x^2} + \frac{15}{4\left(x - \frac{1}{2}\right)^2} - \frac{3}{x - \frac{1}{2}}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

For the pole at $x = \frac{1}{2}$ let b be the coefficient of $\frac{1}{\left(x-\frac{1}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{15}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{2} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{32x^2 + 16x - 1}{4\left(2x^2 - x\right)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = 2$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -1
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{32x^2 + 16x - 1}{4\left(2x^2 - x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$
$\frac{1}{2}$	2	0	$\frac{5}{2}$	$-\frac{3}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	2	-1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -1$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^+ + \alpha_{c_2}^-\right) \\
&= -1 - (-1) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x-c_2} \right) + (-)[\sqrt{r}]_\infty \\
&= \frac{1}{2x} - \frac{3}{2\left(x-\frac{1}{2}\right)} + (-)\,(0) \\
&= \frac{1}{2x} - \frac{3}{2\left(x-\frac{1}{2}\right)} \\
&= \frac{-1-4x}{4x^2-2x}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{2x} - \frac{3}{2\left(x - \frac{1}{2}\right)}\right)(0) + \left(\left(-\frac{1}{2x^2} + \frac{3}{2\left(x - \frac{1}{2}\right)^2}\right) + \left(\frac{1}{2x} - \frac{3}{2\left(x - \frac{1}{2}\right)}\right)^2 - \left(\frac{32x^2 + 16x - 1}{4\left(2x^2 - x\right)^2}\right)\right)$$

$$0 = ($$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= \mathrm{e}^{\int \left(\frac{1}{2x} - \frac{3}{2\left(x - \frac{1}{2}\right)}\right) dx} \\ &= \frac{\sqrt{x}}{(-1 + 2x)^{3/2}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2} \frac{3x}{-2x^3 + x^2} \, dx} \\ &= z_1 e^{\frac{3\ln(-1+2x)}{2} - \frac{3\ln(x)}{2}} \\ &= z_1 \left(\frac{(-1 + 2x)^{3/2}}{x^{3/2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{1}{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{3x}{-2x^3 + x^2} \, dx}}{(y_1)^2} \, dx \\ &= y_1 \int \frac{e^{3\ln(-1+2x) - 3\ln(x)}}{(y_1)^2} \, dx \\ &= y_1 \left(\frac{8x^3}{3} + \frac{1}{2} + 6x - 6x^2 - \ln(x)\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\frac{1}{x}\right) + c_2 \left(\frac{1}{x}\left(\frac{8x^3}{3} + \frac{1}{2} + 6x - 6x^2 - \ln(x)\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2(-2x+1)\left(\frac{d^2}{dx^2}y(x)\right)+3x\left(\frac{d}{dx}y(x)\right)+(4x+1)\,y(x)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$
- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x)=\frac{(4x+1)y(x)}{x^2(2x-1)}+\frac{3\left(\frac{d}{dx}y(x)\right)}{x(2x-1)}$
- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x)-\frac{3\left(\frac{d}{dx}y(x)\right)}{x(2x-1)}-\frac{(4x+1)y(x)}{x^2(2x-1)}=0$

☐ Check to see if x_0 is a regular singular point

  - Define functions

    $\left[P_2(x)=-\frac{3}{x(2x-1)},P_3(x)=-\frac{4x+1}{x^2(2x-1)}\right]$
  - $x\cdot P_2(x)$ is analytic at $x=0$

    $\left(x\cdot P_2(x)\right)\Bigg|_{x=0}=3$
  - $x^2\cdot P_3(x)$ is analytic at $x=0$

    $\left(x^2\cdot P_3(x)\right)\Bigg|_{x=0}=1$
  - $x=0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=0$
- Multiply by denominators

  $x^2(2x-1)\left(\frac{d^2}{dx^2}y(x)\right)-3x\left(\frac{d}{dx}y(x)\right)+(-4x-1)\,y(x)=0$
- Assume series solution for $y(x)$

  $y(x)=\sum_{k=0}^{\infty}a_k x^{k+r}$

☐ Rewrite ODE with series expansions

  - Convert $x^m\cdot y(x)$ to series expansion for $m=0..1$

    $x^m\cdot y(x)=\sum_{k=0}^{\infty}a_k x^{k+r+m}$
  - Shift index using $k->k-m$

    $x^m\cdot y(x)=\sum_{k=m}^{\infty}a_{k-m}x^{k+r}$
  - Convert $x\cdot\left(\frac{d}{dx}y(x)\right)$ to series expansion

    $x\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,x^{k+r}$
  - Convert $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m=2..3$

    $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,x^{k+r-2+m}$
  - Shift index using $k->k+2-m$

    $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=-2+m}^{\infty}a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$

  Rewrite ODE with series expansions

  $-a_0(1+r)^2x^r+\left(\sum_{k=1}^{\infty}\left(-a_k(k+r+1)^2+2a_{k-1}(k+r)\,(k-3+r)\right)x^{k+r}\right)=0$
- $a_0$cannot be 0 by assumption, giving the indicial equation

$-(1+r)^2 = 0$

- Values of r that satisfy the indicial equation
  $r = -1$
- Each term in the series must be 0, giving the recursion relation
  $-a_k(k+r+1)^2 + 2a_{k-1}(k+r)(k-3+r) = 0$
- Shift index using $k- >k+1$
  $-a_{k+1}(k+2+r)^2 + 2a_k(k+r+1)(k+r-2) = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+1} = \frac{2a_k(k+r+1)(k+r-2)}{(k+2+r)^2}$
- Recursion relation for $r = -1$; series terminates at $k = 3$
  $a_{k+1} = \frac{2a_k k(k-3)}{(k+1)^2}$
- Apply recursion relation for $k = 0$
  $a_1 = 0$
- Apply recursion relation for $k = 1$
  $a_2 = -a_1$
- Express in terms of a_0
  $a_2 = 0$
- Apply recursion relation for $k = 2$
  $a_3 = -\frac{4a_2}{9}$
- Express in terms of a_0
  $a_3 = 0$
- Terminating series solution of the ODE for $r = -1$. Use reduction of order to find the second
  $y(x) = a_0 \cdot 0$

2.1.150 Problem 152

Internal problem ID [9322]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 152
Date solved : `Monday, January 27, 2025 at 06:01:27 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x(1+x)\, y''+(1-x)\, y'+y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.220 (sec)

Writing the ode as

$$\left(x^2+x\right) y''+(1-x)\, y'+y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2+x \\ B &= 1-x \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r=\frac{-x^2-10x-1}{4\left(x^2+x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -x^2-10x-1 \\ t &= 4\left(x^2+x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{-x^2-10x-1}{4\left(x^2+x\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.284: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^2 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4x^2} + \frac{2}{(1 + x)^2} + \frac{2}{1 + x} - \frac{2}{x}$$

For the pole at $x = -1$ let b be the coefficient of $\frac{1}{(1+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -1 \end{aligned}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{-x^2 - 10x - 1}{4\left(x^2 + x\right)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{1}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{-x^2 - 10x - 1}{4\left(x^2 + x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
-1	2	0	2	-1
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^+\right) \\
&= \frac{1}{2} - \left(-\frac{1}{2}\right) \\
&= 1
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x - c_1} \right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x - c_2} \right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{1}{1+x} + \frac{1}{2x} + (-)(0) \\
&= -\frac{1}{1+x} + \frac{1}{2x} \\
&= -\frac{x-1}{2x(1+x)}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{1+x} + \frac{1}{2x}\right)(1) + \left(\left(\frac{1}{(1+x)^2} - \frac{1}{2x^2}\right) + \left(-\frac{1}{1+x} + \frac{1}{2x}\right)^2 - \left(\frac{-x^2 - 10x - 1}{4\,(x^2+x)^2}\right)\right) = 0$$

$$\frac{1 + a_0}{x\,(1+x)} = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = -1\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x - 1$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx} \\
&= (x-1)\, e^{\int \left(-\frac{1}{1+x} + \frac{1}{2x}\right) dx} \\
&= (x-1)\, e^{\frac{\ln(x)}{2} - \ln(1+x)} \\
&= \frac{(x-1)\sqrt{x}}{1+x}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{1-x}{x^2+x}\, dx} \\
&= z_1 e^{-\frac{\ln(x)}{2} + \ln(1+x)} \\
&= z_1 \left(\frac{1+x}{\sqrt{x}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = x - 1$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{1-x}{x^2+x}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-\ln(x) + 2\ln(1+x)}}{(y_1)^2}\, dx \\
&= y_1 \left(-\frac{4}{x-1} + \ln(x)\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(x-1) + c_2\left(x - 1\left(-\frac{4}{x-1} + \ln(x)\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x(x+1)\left(\frac{d^2}{dx^2}y(x)\right) + (1-x)\left(\frac{d}{dx}y(x)\right) + y(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = -\frac{y(x)}{x(x+1)} + \frac{(x-1)\left(\frac{d}{dx}y(x)\right)}{x(x+1)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dx^2}y(x) - \frac{(x-1)\left(\frac{d}{dx}y(x)\right)}{x(x+1)} + \frac{y(x)}{x(x+1)} = 0$

□ Check to see if x_0 is a regular singular point

  - Define functions

    $\left[P_2(x) = -\frac{x-1}{x(x+1)}, P_3(x) = \frac{1}{x(x+1)}\right]$

  - $(x+1)\cdot P_2(x)$ is analytic at $x=-1$

    $\left((x+1)\cdot P_2(x)\right)\bigg|_{x=-1} = -2$

  - $(x+1)^2\cdot P_3(x)$ is analytic at $x=-1$

    $\left((x+1)^2\cdot P_3(x)\right)\bigg|_{x=-1} = 0$

  - $x=-1$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = -1$

- Multiply by denominators

  $x(x+1)\left(\frac{d^2}{dx^2}y(x)\right) + (1-x)\left(\frac{d}{dx}y(x)\right) + y(x) = 0$

- Change variables using $x = u-1$ so that the regular singular point is at $u=0$

  $(u^2-u)\left(\frac{d^2}{du^2}y(u)\right) + (2-u)\left(\frac{d}{du}y(u)\right) + y(u) = 0$

- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

□ Rewrite ODE with series expansions

  - Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..1$

    $u^m\cdot\left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,u^{k+r-1+m}$

  - Shift index using $k->k+1-m$

    $u^m\cdot\left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,u^{k+r}$

  - Convert $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m = 1..2$

$$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,u^{k+r-2+m}$$

- Shift index using $k->k+2-m$

$$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,u^{k+r}$$

Rewrite ODE with series expansions

$$-a_0 r(-3+r)\,u^{-1+r} + \left(\sum_{k=0}^{\infty} \left(-a_{k+1}(k+1+r)\,(k-2+r) + a_k(k+r-1)^2\right) u^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $-r(-3+r) = 0$
- Values of r that satisfy the indicial equation
  $r \in \{0, 3\}$
- Each term in the series must be 0, giving the recursion relation
  $-a_{k+1}(k+1+r)\,(k-2+r) + a_k(k+r-1)^2 = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+1} = \frac{a_k(k+r-1)^2}{(k+1+r)(k-2+r)}$
- Recursion relation for $r = 0$; series terminates at $k = 1$
  $a_{k+1} = \frac{a_k(k-1)^2}{(k+1)(k-2)}$
- Apply recursion relation for $k = 0$
  $a_1 = -\frac{a_0}{2}$
- Terminating series solution of the ODE for $r = 0$. Use reduction of order to find the second linea
  $y(u) = a_0 \cdot \left(1 - \frac{u}{2}\right)$
- Revert the change of variables $u = x + 1$
  $\left[y(x) = a_0\left(-\frac{x}{2} + \frac{1}{2}\right)\right]$
- Recursion relation for $r = 3$
  $a_{k+1} = \frac{a_k(k+2)^2}{(k+4)(k+1)}$
- Solution for $r = 3$
  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+3}, a_{k+1} = \frac{a_k(k+2)^2}{(k+4)(k+1)}\right]$
- Revert the change of variables $u = x + 1$
  $\left[y(x) = \sum_{k=0}^{\infty} a_k(x+1)^{k+3}, a_{k+1} = \frac{a_k(k+2)^2}{(k+4)(k+1)}\right]$
- Combine solutions and rename parameters
  $\left[y(x) = a_0\left(-\frac{x}{2} + \frac{1}{2}\right) + \left(\sum_{k=0}^{\infty} b_k(x+1)^{k+3}\right), b_{k+1} = \frac{b_k(k+2)^2}{(4+k)(k+1)}\right]$

2.1.151 Problem 153

Internal problem ID [9323]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 153
Date solved : `Monday, January 27, 2025 at 06:01:28 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2(1-x)\,y''-x(3-5x)\,y'+(4-5x)\,y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.216 (sec)

Writing the ode as

$$\left(-x^3+x^2\right)y''+\left(5x^2-3x\right)y'+(4-5x)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=-x^3+x^2\\B&=5x^2-3x\\C&=4-5x\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned}r&=\frac{s}{t}\\&=\frac{2AB'-2BA'+B^2-4AC}{4A^2}\end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{15x^2-6x-1}{4\left(x^2-x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned}s&=15x^2-6x-1\\t&=4\left(x^2-x\right)^2\end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{15x^2-6x-1}{4\left(x^2-x\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.286: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^2 - x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = 1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{2}{x} - \frac{1}{4x^2} + \frac{2}{(-1+x)^2} + \frac{2}{-1+x}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

For the pole at $x = 1$ let b be the coefficient of $\frac{1}{(-1+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1 \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{15x^2 - 6x - 1}{4\left(x^2 - x\right)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{15}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{2}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{15x^2 - 6x - 1}{4\left(x^2 - x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$
1	2	0	2	-1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{5}{2}$	$-\frac{3}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{5}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^+ + \alpha_{c_2}^+\right) \\
&= \frac{5}{2} - \left(\frac{5}{2}\right) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1}\right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x-c_2}\right) + (+)[\sqrt{r}]_\infty \\
&= \frac{1}{2x} + \frac{2}{-1+x} + (0) \\
&= \frac{1}{2x} + \frac{2}{-1+x} \\
&= \frac{-1+5x}{2x\,(-1+x)}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{2x} + \frac{2}{-1+x}\right)(0) + \left(\left(-\frac{1}{2x^2} - \frac{2}{(-1+x)^2}\right) + \left(\frac{1}{2x} + \frac{2}{-1+x}\right)^2 - \left(\frac{15x^2 - 6x - 1}{4(x^2 - x)^2}\right)\right) = 0$$

$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega\, dx} \\ &= e^{\int \left(\frac{1}{2x} + \frac{2}{-1+x}\right) dx} \\ &= (-1+x)^2 \sqrt{x} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{5x^2 - 3x}{-x^3 + x^2}\, dx} \\ &= z_1 e^{\ln(-1+x) + \frac{3\ln(x)}{2}} \\ &= z_1 \left((-1+x)\, x^{3/2}\right) \end{aligned}$$

Which simplifies to

$$y_1 = (-1+x)^3 x^2$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{5x^2 - 3x}{-x^3 + x^2}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{2\ln(-1+x) + 3\ln(x)}}{(y_1)^2}\, dx \\ &= y_1 \left(-\frac{1}{3(-1+x)^3} - \frac{1}{-1+x} + \frac{1}{2(-1+x)^2} - \ln(-1+x) + \ln(x)\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left((-1+x)^3 x^2\right) \\ &\quad + c_2\left((-1+x)^3 x^2 \left(-\frac{1}{3(-1+x)^3} - \frac{1}{-1+x} + \frac{1}{2(-1+x)^2} - \ln(-1+x) + \ln(x)\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^2(1-x)\left(\frac{d^2}{dx^2}y(x)\right)-x(3-5x)\left(\frac{d}{dx}y(x)\right)+(4-5x)\,y(x)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x)=-\frac{(-4+5x)y(x)}{x^2(x-1)}+\frac{(-3+5x)\left(\frac{d}{dx}y(x)\right)}{x(x-1)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x)-\frac{(-3+5x)\left(\frac{d}{dx}y(x)\right)}{x(x-1)}+\frac{(-4+5x)y(x)}{x^2(x-1)}=0$

□ Check to see if x_0 is a regular singular point

  - Define functions

    $\left[P_2(x)=-\frac{-3+5x}{x(x-1)},P_3(x)=\frac{-4+5x}{x^2(x-1)}\right]$

  - $x\cdot P_2(x)$ is analytic at $x=0$

    $\left.(x\cdot P_2(x))\right|_{x=0}=-3$

  - $x^2\cdot P_3(x)$ is analytic at $x=0$

    $\left.(x^2\cdot P_3(x))\right|_{x=0}=4$

  - $x=0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=0$

- Multiply by denominators

  $x^2(x-1)\left(\frac{d^2}{dx^2}y(x)\right)-x(-3+5x)\left(\frac{d}{dx}y(x)\right)+(-4+5x)\,y(x)=0$

- Assume series solution for $y(x)$

  $y(x)=\sum_{k=0}^{\infty}a_kx^{k+r}$

□ Rewrite ODE with series expansions

  - Convert $x^m\cdot y(x)$ to series expansion for $m=0..1$

    $x^m\cdot y(x)=\sum_{k=0}^{\infty}a_kx^{k+r+m}$

  - Shift index using $k->k-m$

    $x^m\cdot y(x)=\sum_{k=m}^{\infty}a_{k-m}x^{k+r}$

  - Convert $x^m\cdot\left(\frac{d}{dx}y(x)\right)$ to series expansion for $m=1..2$

    $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,x^{k+r-1+m}$

  - Shift index using $k->k+1-m$

    $x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,x^{k+r}$

  - Convert $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m=2..3$

    $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,x^{k+r-2+m}$

  - Shift index using $k->k+2-m$

    $x^m\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=-2+m}^{\infty}a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$

  Rewrite ODE with series expansions

$$-a_0(-2+r)^2 x^r + \left(\sum_{k=1}^{\infty} \left(-a_k(k+r-2)^2 + a_{k-1}(k+r-2)(k-6+r)\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $-(-2+r)^2 = 0$
- Values of r that satisfy the indicial equation
  $r = 2$
- Each term in the series must be 0, giving the recursion relation
  $-a_k(k+r-2)^2 + a_{k-1}(k+r-2)(k-6+r) = 0$
- Shift index using $k- >k+1$
  $-a_{k+1}(k+r-1)^2 + a_k(k+r-1)(k+r-5) = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+1} = \frac{a_k(k+r-5)}{k+r-1}$
- Recursion relation for $r = 2$; series terminates at $k = 3$
  $a_{k+1} = \frac{a_k(k-3)}{k+1}$
- Apply recursion relation for $k = 0$
  $a_1 = -3a_0$
- Apply recursion relation for $k = 1$
  $a_2 = -a_1$
- Express in terms of a_0
  $a_2 = 3a_0$
- Apply recursion relation for $k = 2$
  $a_3 = -\frac{a_2}{3}$
- Express in terms of a_0
  $a_3 = -a_0$
- Terminating series solution of the ODE for $r = 2$. Use reduction of order to find the second li
  $y(x) = a_0 \cdot (-x^3 + 3x^2 - 3x + 1)$

2.1.152 Problem 154

Internal problem ID [9324]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 154
Date solved : `Monday, January 27, 2025 at 06:01:28 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2\left(x^2+1\right) y''-x\left(9x^2+1\right) y'+\left(25x^2+1\right) y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.303 (sec)

Writing the ode as

$$\left(x^4+x^2\right) y''+\left(-9x^3-x\right) y'+\left(25x^2+1\right) y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^4+x^2 \\ B &= -9x^3-x \\ C &= 25x^2+1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r=\frac{-x^4-98x^2-1}{4\left(x^3+x\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -x^4-98x^2-1 \\ t &= 4\left(x^3+x\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{-x^4-98x^2-1}{4\left(x^3+x\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 2.288: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 4 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^3 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = i$ of order 2. There is a pole at $x = -i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4x^2} + \frac{6}{(x-i)^2} + \frac{6}{(x+i)^2} + \frac{6i}{x-i} - \frac{6i}{x+i}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

For the pole at $x = i$ let b be the coefficient of $\frac{1}{(x-i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 6$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 3 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -2 \end{aligned}$$

For the pole at $x = -i$ let b be the coefficient of $\frac{1}{(x+i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 6$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 3 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -2\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{-x^4 - 98x^2 - 1}{4(x^3 + x)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{1}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{-x^4 - 98x^2 - 1}{4(x^3 + x)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$
i	2	0	3	-2
$-i$	2	0	3	-2

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$\begin{aligned}d &= \alpha_\infty^- - \left(\alpha_{c_1}^+ + \alpha_{c_2}^- + \alpha_{c_3}^-\right) \\ &= \frac{1}{2} - \left(-\frac{7}{2}\right) \\ &= 4\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$
\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x-c_1}\right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{-}}{x-c_2}\right) + \left((-)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^{-}}{x-c_3}\right) + (-)[\sqrt{r}]_{\infty} \\
&= \frac{1}{2x} - \frac{2}{x-i} - \frac{2}{x+i} + (-)\,(0) \\
&= \frac{1}{2x} - \frac{2}{x-i} - \frac{2}{x+i} \\
&= \frac{1}{2x} - \frac{4x}{x^2+1}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 4$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = x^4 + a_3 x^3 + a_2 x^2 + a_1 x + a_0 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
\left(12x^2 + 6xa_3 + 2a_2\right) + 2\left(\frac{1}{2x} - \frac{2}{x-i} - \frac{2}{x+i}\right)\left(4x^3 + 3x^2 a_3 + 2a_2 x + a_1\right) + \left(\left(-\frac{1}{2x^2} + \frac{2}{(x-i)^2} + \frac{2}{(x+i}\right.\right.
$$

$$
\left(x^4 a_3 + 4(4 + a\right.
$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$
\{a_0 = 1, a_1 = 0, a_2 = -4, a_3 = 0\}
$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$
p(x) = x^4 - 4x^2 + 1
$$

Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \left(x^4 - 4x^2 + 1\right) e^{\int \left(\frac{1}{2x} - \frac{2}{x-i} - \frac{2}{x+i}\right) dx} \\
&= \left(x^4 - 4x^2 + 1\right) e^{\frac{\ln(x)}{2} - 2\ln(x^2+1)} \\
&= \frac{\left(x^4 - 4x^2 + 1\right)\sqrt{x}}{\left(x^2+1\right)^2}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{-9x^3 - x}{x^4 + x^2} \, dx} \\
&= z_1 e^{\frac{\ln(x)}{2} + 2\ln(x^2+1)} \\
&= z_1 \left(\sqrt{x}\left(x^2+1\right)^2\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = x^5 - 4x^3 + x
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-9x^3-x}{x^4+x^2} dx}}{(y_1)^2} dx \\
&= y_1 \int \frac{e^{\ln(x)+4\ln(x^2+1)}}{(y_1)^2} dx \\
&= y_1 \left(\ln(x) + \frac{-6x^2+3}{x^4-4x^2+1} \right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 (x^5 - 4x^3 + x) + c_2 \left(x^5 - 4x^3 + x \left(\ln(x) + \frac{-6x^2+3}{x^4-4x^2+1} \right) \right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

2.1.153 Problem 155

Internal problem ID [9325]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 155
Date solved : `Monday, January 27, 2025 at 06:01:29 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$9x^2y'' + 3x\left(-x^2+1\right)y' + \left(7x^2+1\right)y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 1.111 (sec)

Writing the ode as

$$9x^2y'' + \left(-3x^3+3x\right)y' + \left(7x^2+1\right)y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 9x^2 \\ B &= -3x^3+3x \\ C &= 7x^2+1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^4 - 36x^2 - 9}{36x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^4 - 36x^2 - 9 \\ t &= 36x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^4 - 36x^2 - 9}{36x^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.290: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 4 \\ &= -2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 36x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{x^2}{36} - 1 - \frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x}{6} - \frac{3}{x} - \frac{111}{4x^3} - \frac{999}{2x^5} - \frac{180819}{16x^7} - \frac{2292705}{8x^9} - \frac{249239511}{32x^{11}} - \frac{3548540907}{16x^{13}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{6}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= \frac{x}{6} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{x^2}{36}$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^4 - 36x^2 - 9}{36x^2} \\ &= Q + \frac{R}{36x^2} \\ &= \left(\frac{x^2}{36} - 1\right) + \left(-\frac{1}{4x^2}\right) \\ &= \frac{x^2}{36} - 1 - \frac{1}{4x^2} \end{aligned}$$

We see that the coefficient of the term x in the quotient is -1. Now b can be found.

$$\begin{aligned} b &= (-1) - (0) \\ &= -1 \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{x}{6} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-1}{\frac{1}{6}} - 1\right) &&= -\frac{7}{2} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-1}{\frac{1}{6}} - 1\right) &&= \frac{5}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^4 - 36x^2 - 9}{36x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-2	$\frac{x}{6}$	$-\frac{7}{2}$	$\frac{5}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{5}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^+\right) \\ &= \frac{5}{2} - \left(\frac{1}{2}\right) \\ &= 2 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{1}{2x} + (-)\left(\frac{x}{6}\right) \\ &= \frac{1}{2x} - \frac{x}{6} \\ &= \frac{1}{2x} - \frac{x}{6} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 2$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x^2 + a_1 x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(2) + 2\left(\frac{1}{2x} - \frac{x}{6}\right)(2x + a_1) + \left(\left(-\frac{1}{2x^2} - \frac{1}{6}\right) + \left(\frac{1}{2x} - \frac{x}{6}\right)^2 - \left(\frac{x^4 - 36x^2 - 9}{36x^2}\right) \right) = 0$$

$$\frac{x^2 a_1 + 2(6 + a_0)\, x + 3a_1}{3x} = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = -6, a_1 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^2 - 6$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \left(x^2-6\right) e^{\int \left(\frac{1}{2x}-\frac{x}{6}\right) dx} \\
&= \left(x^2-6\right) e^{-\frac{x^2}{12}+\frac{\ln(x)}{2}} \\
&= \left(x^2-6\right) \sqrt{x}\, e^{-\frac{x^2}{12}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-3x^3+3x}{9x^2} \, dx} \\
&= z_1 e^{\frac{x^2}{12}-\frac{\ln(x)}{6}} \\
&= z_1 \left(\frac{e^{\frac{x^2}{12}}}{x^{1/6}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = x^{1/3}\left(x^2-6\right)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-3x^3+3x}{9x^2} \, dx}}{\left(y_1\right)^2} \, dx \\
&= y_1 \int \frac{e^{\frac{x^2}{6}-\frac{\ln(x)}{3}}}{\left(y_1\right)^2} \, dx \\
&= y_1 \left(\int \frac{e^{\frac{x^2}{6}-\frac{\ln(x)}{3}}}{x^{2/3}\left(x^2-6\right)^2} dx\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(x^{1/3}\left(x^2-6\right)\right) + c_2\left(x^{1/3}\left(x^2-6\right)\left(\int \frac{e^{\frac{x^2}{6}-\frac{\ln(x)}{3}}}{x^{2/3}\left(x^2-6\right)^2} dx\right)\right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,x^{k+r-1+m}$

- ◦ Shift index using $k->k+1-m$

$x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,x^{k+r}$

- ◦ Convert $x^2\cdot\left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

$x^2\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,x^{k+r}$

Rewrite ODE with series expansions

$a_0(-1+3r)^2\,x^r+a_1(2+3r)^2\,x^{1+r}+\left(\sum_{k=2}^{\infty}\left(a_k(3k+3r-1)^2-a_{k-2}(3k-13+3r)\right)x^{k+r}\right)=0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$(-1+3r)^2 = 0$

- Values of r that satisfy the indicial equation

  $r = \frac{1}{3}$

- Each term must be 0

  $a_1(2+3r)^2 = 0$

- Solve for the dependent coefficient(s)

  $a_1 = 0$

- Each term in the series must be 0, giving the recursion relation

  $a_k(3k+3r-1)^2 + (-3k+13-3r)\, a_{k-2} = 0$

- Shift index using $k->k+2$

  $a_{k+2}(3k+5+3r)^2 + a_k(-3k-3r+7) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+2} = \frac{a_k(3k+3r-7)}{(3k+5+3r)^2}$

- Recursion relation for $r = \frac{1}{3}$; series terminates at $k = 2$

  $a_{k+2} = \frac{a_k(3k-6)}{(3k+6)^2}$

- Solution for $r = \frac{1}{3}$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{3}}, a_{k+2} = \frac{a_k(3k-6)}{(3k+6)^2}, a_1 = 0\right]$

2.1.154 Problem 156

Internal problem ID [9326]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 156
Date solved : `Monday, January 27, 2025 at 06:01:31 PM`
CAS classification : `[[_2nd_order, _exact, _linear, _homogeneous]]`

Solve

$$x\left(x^{2}+1\right) y''+\left(-x^{2}+1\right) y'-8xy=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.348 (sec)

Writing the ode as

$$\left(x^{3}+x\right) y''+\left(-x^{2}+1\right) y'-8xy=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^{3}+x \\ B &= -x^{2}+1 \\ C &= -8x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^{2}-4AC}{4A^{2}} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r=\frac{35x^{4}+22x^{2}-1}{4\left(x^{3}+x\right)^{2}} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 35x^{4}+22x^{2}-1 \\ t &= 4\left(x^{3}+x\right)^{2} \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{35x^{4}+22x^{2}-1}{4\left(x^{3}+x\right)^{2}}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.292: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 6 - 4 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^3 + x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = i$ of order 2. There is a pole at $x = -i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{3}{4\,(x-i)^2} + \frac{3}{4\,(x+i)^2} - \frac{15i}{4\,(x-i)} + \frac{15i}{4\,(x+i)} - \frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

For the pole at $x = i$ let b be the coefficient of $\frac{1}{(x-i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

For the pole at $x = -i$ let b be the coefficient of $\frac{1}{(x+i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2}\\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{35x^4 + 22x^2 - 1}{4\left(x^3 + x\right)^2}$$

Since the $\gcd(s, t) = 1$. This gives $b = \frac{35}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= 0\\ \alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{7}{2}\\ \alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{5}{2}\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{35x^4 + 22x^2 - 1}{4\left(x^3 + x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$
i	2	0	$\frac{3}{2}$	$-\frac{1}{2}$
$-i$	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{7}{2}$	$-\frac{5}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{7}{2}$ then

$$\begin{aligned}d &= \alpha_\infty^+ - \left(\alpha_{c_1}^+ + \alpha_{c_2}^+ + \alpha_{c_3}^+\right)\\ &= \frac{7}{2} - \left(\frac{7}{2}\right)\\ &= 0\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x-c_1}\right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{+}}{x-c_2}\right) + \left((+)[\sqrt{r}]_{c_3} + \frac{\alpha_{c_3}^{+}}{x-c_3}\right) + (+)[\sqrt{r}]_{\infty} \\
&= \frac{1}{2x} + \frac{3}{2(x-i)} + \frac{3}{2(x+i)} + (0) \\
&= \frac{1}{2x} + \frac{3}{2(x-i)} + \frac{3}{2(x+i)} \\
&= \frac{1}{2x} + \frac{3x}{x^2+1}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{2x} + \frac{3}{2(x-i)} + \frac{3}{2(x+i)}\right)(0) + \left(\left(-\frac{1}{2x^2} - \frac{3}{2(x-i)^2} - \frac{3}{2(x+i)^2}\right) + \left(\frac{1}{2x} + \frac{3}{2(x-i)} + \frac{}{2(}\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(\frac{1}{2x} + \frac{3}{2(x-i)} + \frac{3}{2(x+i)}\right) dx} \\
&= (x^2+1)^{3/2} \sqrt{x}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-x^2+1}{x^3+x}\, dx} \\
&= z_1 e^{\frac{\ln(x^2+1)}{2} - \frac{\ln(x)}{2}} \\
&= z_1 \left(\frac{\sqrt{x^2+1}}{\sqrt{x}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = (x^2+1)^2$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-x^2+1}{x^3+x}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{\ln(x^2+1) - \ln(x)}}{(y_1)^2}\, dx \\
&= y_1 \left(\frac{1}{2x^2+2} + \frac{1}{4(x^2+1)^2} - \frac{\ln(x^2+1)}{2} + \ln(x)\right)
\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\left(x^2+1\right)^2\right) + c_2\left(\left(x^2+1\right)^2\left(\frac{1}{2x^2+2} + \frac{1}{4\left(x^2+1\right)^2} - \frac{\ln\left(x^2+1\right)}{2} + \ln\left(x\right)\right)\right)
\end{aligned}
$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$x(x^2+1)\left(\frac{d^2}{dx^2}y(x)\right) + (-x^2+1)\left(\frac{d}{dx}y(x)\right) - 8xy(x) = 0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x) = \frac{8y(x)}{x^2+1} + \frac{(x^2-1)\left(\frac{d}{dx}y(x)\right)}{x(x^2+1)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x) - \frac{(x^2-1)\left(\frac{d}{dx}y(x)\right)}{x(x^2+1)} - \frac{8y(x)}{x^2+1} = 0$

☐ Check to see if x_0 is a regular singular point

  ◦ Define functions

    $\left[P_2(x) = -\frac{x^2-1}{x(x^2+1)}, P_3(x) = -\frac{8}{x^2+1}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left.(x \cdot P_2(x))\right|_{x=0} = 1$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $\left.(x^2 \cdot P_3(x))\right|_{x=0} = 0$

  ◦ $x = 0$is a regular singular point

    Check to see if x_0 is a regular singular point

    $x_0 = 0$

- Multiply by denominators

  $x(x^2+1)\left(\frac{d^2}{dx^2}y(x)\right) + (-x^2+1)\left(\frac{d}{dx}y(x)\right) - 8xy(x) = 0$

- Assume series solution for $y(x)$

  $y(x) = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

  ◦ Convert $x \cdot y(x)$ to series expansion

    $x \cdot y(x) = \sum_{k=0}^{\infty} a_k x^{k+r+1}$

  ◦ Shift index using $k- >k-1$

    $x \cdot y(x) = \sum_{k=1}^{\infty} a_{k-1} x^{k+r}$

  ◦ Convert $x^m \cdot \left(\frac{d}{dx}y(x)\right)$ to series expansion for $m = 0..2$

    $x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1+m}$

  ◦ Shift index using $k- >k+1-m$

$$x^m \cdot \left(\frac{d}{dx}y(x)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$$

- Convert $x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion for $m = 1..3$

$$x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-2+m}$$

- Shift index using $k- > k+2-m$

$$x^m \cdot \left(\frac{d^2}{dx^2}y(x)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0r^2x^{-1+r} + a_1(1+r)^2 x^r + \left(\sum_{k=1}^{\infty} \left(a_{k+1}(k+r+1)^2 + a_{k-1}(k+r+1)\,(k-5+r)\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r^2 = 0$
- Values of r that satisfy the indicial equation

  $r = 0$
- Each term must be 0

  $a_1(1+r)^2 = 0$
- Each term in the series must be 0, giving the recursion relation

  $((a_{k-1} + a_{k+1})\, k - 5a_{k-1} + a_{k+1})\,(k+1) = 0$
- Shift index using $k- > k+1$

  $((a_k + a_{k+2})\,(k+1) - 5a_k + a_{k+2})\,(k+2) = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{a_k(k-4)}{k+2}$
- Recursion relation for $r = 0$; series terminates at $k = 4$

  $a_{k+2} = -\frac{a_k(k-4)}{k+2}$
- Solution for $r = 0$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^k, a_{k+2} = -\frac{a_k(k-4)}{k+2}, a_1 = 0\right]$

2.1.155 Problem 157

Internal problem ID [9327]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 157
Date solved : `Monday, January 27, 2025 at 06:01:31 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$4x^2y'' + 2x\left(-x^2+4\right)y' + \left(7x^2+1\right)y = 0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.675 (sec)

Writing the ode as

$$4x^2y'' + \left(-2x^3+8x\right)y' + \left(7x^2+1\right)y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4x^2 \\ B &= -2x^3+8x \\ C &= 7x^2+1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^4 - 40x^2 - 4}{16x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^4 - 40x^2 - 4 \\ t &= 16x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^4 - 40x^2 - 4}{16x^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.294: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 4 \\ &= -2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{x^2}{16} - \frac{5}{2} - \frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{x}{4} - \frac{5}{x} - \frac{101}{2x^3} - \frac{1010}{x^5} - \frac{50601}{2x^7} - \frac{710030}{x^9} - \frac{21351501}{x^{11}} - \frac{672670100}{x^{13}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{4}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= \frac{x}{4}\end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{x^2}{16}$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned}r &= \frac{s}{t} \\ &= \frac{x^4 - 40x^2 - 4}{16x^2} \\ &= Q + \frac{R}{16x^2} \\ &= \left(\frac{x^2}{16} - \frac{5}{2}\right) + \left(-\frac{1}{4x^2}\right) \\ &= \frac{x^2}{16} - \frac{5}{2} - \frac{1}{4x^2}\end{aligned}$$

We see that the coefficient of the term x in the quotient is $-\frac{5}{2}$. Now b can be found.

$$\begin{aligned}b &= \left(-\frac{5}{2}\right) - (0) \\ &= -\frac{5}{2}\end{aligned}$$

Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= \frac{x}{4} \\ \alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{5}{2}}{\frac{1}{4}} - 1\right) &&= -\frac{11}{2} \\ \alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{5}{2}}{\frac{1}{4}} - 1\right) &&= \frac{9}{2}\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^4 - 40x^2 - 4}{16x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-2	$\frac{x}{4}$	$-\frac{11}{2}$	$\frac{9}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{9}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^+\right) \\ &= \frac{9}{2} - \left(\frac{1}{2}\right) \\ &= 4 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^+}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{1}{2x} + (-)\left(\frac{x}{4}\right) \\ &= \frac{1}{2x} - \frac{x}{4} \\ &= \frac{1}{2x} - \frac{x}{4} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 4$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x^4 + a_3x^3 + a_2x^2 + a_1x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\left(12x^2 + 6xa_3 + 2a_2\right) + 2\left(\frac{1}{2x} - \frac{x}{4}\right)\left(4x^3 + 3a_3x^2 + 2a_2x + a_1\right) + \left(\left(-\frac{1}{2x^2} - \frac{1}{4}\right) + \left(\frac{1}{2x} - \frac{x}{4}\right)^2 - \left(\frac{x^4 - 4}{16}\right.\right.$$
$$\frac{x^4a_3 + 2(16 + a_2)\,x^3 + 3(a_1 + 6a_3)\,x^2 + 4(a_0 + 2a_2)\,x}{2x}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 32, a_1 = 0, a_2 = -16, a_3 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x^4 - 16x^2 + 32$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \left(x^4 - 16x^2 + 32\right) e^{\int \left(\frac{1}{2x} - \frac{x}{4}\right) dx} \\
&= \left(x^4 - 16x^2 + 32\right) e^{-\frac{x^2}{8} + \frac{\ln(x)}{2}} \\
&= \left(x^4 - 16x^2 + 32\right) \sqrt{x}\, e^{-\frac{x^2}{8}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{-2x^3+8x}{4x^2} \, dx} \\
&= z_1 e^{\frac{x^2}{8} - \ln(x)} \\
&= z_1 \left(\frac{e^{\frac{x^2}{8}}}{x} \right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{x^4 - 16x^2 + 32}{\sqrt{x}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-2x^3+8x}{4x^2} \, dx}}{(y_1)^2} \, dx \\
&= y_1 \int \frac{e^{\frac{x^2}{4} - 2\ln(x)}}{(y_1)^2} \, dx \\
&= y_1 \left(\int \frac{e^{\frac{x^2}{4} - 2\ln(x)} x}{\left(x^4 - 16x^2 + 32\right)^2} dx \right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{x^4 - 16x^2 + 32}{\sqrt{x}} \right) + c_2 \left(\frac{x^4 - 16x^2 + 32}{\sqrt{x}} \left(\int \frac{e^{\frac{x^2}{4} - 2\ln(x)} x}{\left(x^4 - 16x^2 + 32\right)^2} dx \right) \right)
\end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$4x^2\left(\frac{d^2}{dx^2}y(x)\right)+2x(-x^2+4)\left(\frac{d}{dx}y(x)\right)+(7x^2+1)\,y(x)=0$

- Highest derivative means the order of the ODE is 2

$\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

$\frac{d^2}{dx^2}y(x)=-\frac{(7x^2+1)y(x)}{4x^2}+\frac{(x^2-4)\left(\frac{d}{dx}y(x)\right)}{2x}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

$\frac{d^2}{dx^2}y(x)-\frac{(x^2-4)\left(\frac{d}{dx}y(x)\right)}{2x}+\frac{(7x^2+1)y(x)}{4x^2}=0$

☐ Check to see if $x_0=0$ is a regular singular point

- Define functions

$\left[P_2(x)=-\frac{x^2-4}{2x},P_3(x)=\frac{7x^2+1}{4x^2}\right]$

- $x\cdot P_2(x)$ is analytic at $x=0$

$\left.(x\cdot P_2(x))\right|_{x=0}=2$

- $x^2\cdot P_3(x)$ is analytic at $x=0$

$\left.(x^2\cdot P_3(x))\right|_{x=0}=\frac{1}{4}$

- $x=0$is a regular singular point

Check to see if $x_0=0$ is a regular singular point

$x_0=0$

- Multiply by denominators

$4x^2\left(\frac{d^2}{dx^2}y(x)\right)-2x(x^2-4)\left(\frac{d}{dx}y(x)\right)+(7x^2+1)\,y(x)=0$

- Assume series solution for $y(x)$

$y(x)=\sum_{k=0}^{\infty}a_kx^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $x^m\cdot y(x)$ to series expansion for $m=0..2$

$x^m\cdot y(x)=\sum_{k=0}^{\infty}a_kx^{k+r+m}$

- Shift index using $k->k-m$

$x^m\cdot y(x)=\sum_{k=m}^{\infty}a_{k-m}x^{k+r}$

- Convert $x^m\cdot\left(\frac{d}{dx}y(x)\right)$ to series expansion for $m=1..3$

$x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,x^{k+r-1+m}$

- Shift index using $k->k+1-m$

$x^m\cdot\left(\frac{d}{dx}y(x)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,x^{k+r}$

- Convert $x^2\cdot\left(\frac{d^2}{dx^2}y(x)\right)$ to series expansion

$x^2\cdot\left(\frac{d^2}{dx^2}y(x)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,x^{k+r}$

Rewrite ODE with series expansions

$a_0(1+2r)^2\,x^r+a_1(3+2r)^2\,x^{1+r}+\left(\sum_{k=2}^{\infty}\left(a_k(2k+2r+1)^2-a_{k-2}(2k-11+2r)\right)x^{k+r}\right)=0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$(1+2r)^2 = 0$

- Values of r that satisfy the indicial equation

  $r = -\frac{1}{2}$

- Each term must be 0

  $a_1(3+2r)^2 = 0$

- Solve for the dependent coefficient(s)

  $a_1 = 0$

- Each term in the series must be 0, giving the recursion relation

  $a_k(2k+2r+1)^2 + (-2k+11-2r)\, a_{k-2} = 0$

- Shift index using $k->k+2$

  $a_{k+2}(2k+5+2r)^2 + a_k(-2k-2r+7) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+2} = \frac{a_k(2k+2r-7)}{(2k+5+2r)^2}$

- Recursion relation for $r = -\frac{1}{2}$; series terminates at $k = 4$

  $a_{k+2} = \frac{a_k(2k-8)}{(2k+4)^2}$

- Solution for $r = -\frac{1}{2}$

  $\left[y(x) = \sum_{k=0}^{\infty} a_k x^{k-\frac{1}{2}}, a_{k+2} = \frac{a_k(2k-8)}{(2k+4)^2}, a_1 = 0\right]$

Solve

$$4x^2(1+x)\,y''+8x^2y'+(1+x)\,y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.150 (sec)

Writing the ode as

$$\left(4x^3+4x^2\right)y''+8x^2y'+(1+x)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4x^3+4x^2 \\ B &= 8x^2 \\ C &= 1+x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{-1}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(-\frac{1}{4x^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.296: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = -\frac{1}{4x^2}$$

Since the gcd$(s,t)=1$. This gives $b=-\frac{1}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= 0\\ \alpha_\infty^+ &= \frac{1}{2}+\sqrt{1+4b}=\frac{1}{2}\\ \alpha_\infty^- &= \frac{1}{2}-\sqrt{1+4b}=\frac{1}{2}\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r=-\frac{1}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^-=\frac{1}{2}$ then

$$\begin{aligned}d &= \alpha_\infty^- - (\alpha_{c_1}^-)\\ &= \frac{1}{2}-\left(\frac{1}{2}\right)\\ &= 0\end{aligned}$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$\omega=\sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c+\frac{\alpha_c^{s(c)}}{x-c}\right)+s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}\omega &= \left((-)[\sqrt{r}]_{c_1}+\frac{\alpha_{c_1}^-}{x-c_1}\right)+(-)[\sqrt{r}]_\infty\\ &= \frac{1}{2x}+(-)(0)\\ &= \frac{1}{2x}\\ &= \frac{1}{2x}\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p''+2\omega p'+\left(\omega'+\omega^2-r\right)p=0 \tag{1A}$$

Let

$$p(x)=1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(\frac{1}{2x}\right)(0)+\left(\left(-\frac{1}{2x^2}\right)+\left(\frac{1}{2x}\right)^2-\left(-\frac{1}{4x^2}\right)\right)=0$$
$$0=0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z''=rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= e^{\int \frac{1}{2x} dx} \\ &= \sqrt{x} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{8x^2}{4x^3+4x^2} \, dx} \\ &= z_1 e^{-\ln(1+x)} \\ &= z_1\left(\frac{1}{1+x}\right) \end{aligned}$$

Which simplifies to

$$y_1=\frac{\sqrt{x}}{1+x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2=y_1\int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1\int \frac{e^{\int -\frac{8x^2}{4x^3+4x^2} \, dx}}{(y_1)^2} \, dx \\ &= y_1\int \frac{e^{-2\ln(1+x)}}{(y_1)^2} \, dx \\ &= y_1(\ln(x)) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\frac{\sqrt{x}}{1+x}\right)+c_2\left(\frac{\sqrt{x}}{1+x}(\ln(x))\right) \end{aligned}$$

Will add steps showing solving for IC soon.

2.1.157 Problem 159

Internal problem ID [9329]
Book : Collection of Kovacic problems
Section : section 1
Problem number : 159
Date solved : Monday, January 27, 2025 at 06:01:33 PM
CAS classification : [[_2nd_order, _with_linear_symmetries]]

Solve

$$9x^2(3+x)\,y''+3x(3+7x)\,y'+(3+4x)\,y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.211 (sec)

Writing the ode as

$$\left(9x^3+27x^2\right)y''+\left(21x^2+9x\right)y'+(3+4x)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 9x^3+27x^2\\ B &= 21x^2+9x\\ C &= 3+4x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t}\\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{-1}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1\\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(-\frac{1}{4x^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.298: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = -\frac{1}{4x^2}$$

Since the gcd$(s,t)=1$. This gives $b=-\frac{1}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0\\
\alpha_\infty^+ &= \frac{1}{2}+\sqrt{1+4b}=\frac{1}{2}\\
\alpha_\infty^- &= \frac{1}{2}-\sqrt{1+4b}=\frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r=-\frac{1}{4x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^-=\frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right)\\
&= \frac{1}{2}-\left(\frac{1}{2}\right)\\
&= 0
\end{aligned}
$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$
\omega=\sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c+\frac{\alpha_c^{s(c)}}{x-c}\right)+s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1}+\frac{\alpha_{c_1}^-}{x-c_1}\right)+(-)[\sqrt{r}]_\infty\\
&= \frac{1}{2x}+(-)(0)\\
&= \frac{1}{2x}\\
&= \frac{1}{2x}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p''+2\omega p'+\left(\omega'+\omega^2-r\right)p=0 \tag{1A}
$$

Let

$$
p(x)=1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(\frac{1}{2x}\right)(0)+\left(\left(-\frac{1}{2x^2}\right)+\left(\frac{1}{2x}\right)^2-\left(-\frac{1}{4x^2}\right)\right)=0$$
$$0=0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z''=rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega\, dx} \\ &= \mathrm{e}^{\int \frac{1}{2x} dx} \\ &= \sqrt{x} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{21x^2+9x}{9x^3+27x^2}\, dx} \\ &= z_1 e^{-\ln(3+x)-\frac{\ln(x)}{6}} \\ &= z_1\left(\frac{1}{(3+x)\,x^{1/6}}\right) \end{aligned}$$

Which simplifies to

$$y_1=\frac{x^{1/3}}{3+x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2=y_1\int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1\int \frac{e^{\int -\frac{21x^2+9x}{9x^3+27x^2}\, dx}}{(y_1)^2}\, dx \\ &= y_1\int \frac{e^{-2\ln(3+x)-\frac{\ln(x)}{3}}}{(y_1)^2}\, dx \\ &= y_1\left(\frac{x^2}{9+3x}+\frac{2x}{3+x}+\frac{3}{3+x}-\frac{2\ln(3+x)\,x}{3}-2\ln(3+x)+\ln(x)\right. \\ &\qquad \left.+\frac{2\ln(3+x)\,(3+x)}{3}-\frac{x}{3}-2\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1y_1+c_2y_2 \\ &= c_1\left(\frac{x^{1/3}}{3+x}\right) \\ &\quad +c_2\left(\frac{x^{1/3}}{3+x}\left(\frac{x^2}{9+3x}+\frac{2x}{3+x}+\frac{3}{3+x}-\frac{2\ln(3+x)\,x}{3}-2\ln(3+x)+\ln(x)+\frac{2\ln(3+x)\,(3+x)}{3}-\frac{x}{3}-2\right)\right) \end{aligned}$$

Will add steps showing solving for IC soon.

Maple step by step solution

Let's solve

$9x^2(x+3)\left(\frac{d^2}{dx^2}y(x)\right)+3x(7x+3)\left(\frac{d}{dx}y(x)\right)+(3+4x)\,y(x)=0$

- Highest derivative means the order of the ODE is 2

  $\frac{d^2}{dx^2}y(x)$

- Isolate 2nd derivative

  $\frac{d^2}{dx^2}y(x)=-\frac{(3+4x)y(x)}{9x^2(x+3)}-\frac{(7x+3)\left(\frac{d}{dx}y(x)\right)}{3x(x+3)}$

- Group terms with $y(x)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linea

  $\frac{d^2}{dx^2}y(x)+\frac{(7x+3)\left(\frac{d}{dx}y(x)\right)}{3x(x+3)}+\frac{(3+4x)y(x)}{9x^2(x+3)}=0$

□ Check to see if x_0 is a regular singular point

- ◦ Define functions

  $\left[P_2(x)=\frac{7x+3}{3x(x+3)},P_3(x)=\frac{3+4x}{9x^2(x+3)}\right]$

- ◦ $(x+3)\cdot P_2(x)$ is analytic at $x=-3$

  $\left.((x+3)\cdot P_2(x))\right|_{x=-3}=2$

- ◦ $(x+3)^2\cdot P_3(x)$ is analytic at $x=-3$

  $\left.((x+3)^2\cdot P_3(x))\right|_{x=-3}=0$

- ◦ $x=-3$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=-3$

- Multiply by denominators

  $9x^2(x+3)\left(\frac{d^2}{dx^2}y(x)\right)+3x(7x+3)\left(\frac{d}{dx}y(x)\right)+(3+4x)\,y(x)=0$

- Change variables using $x=u-3$ so that the regular singular point is at $u=0$

  $(9u^3-54u^2+81u)\left(\frac{d^2}{du^2}y(u)\right)+(21u^2-117u+162)\left(\frac{d}{du}y(u)\right)+(-9+4u)\,y(u)=0$

- Assume series solution for $y(u)$

  $y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

□ Rewrite ODE with series expansions

- ◦ Convert $u^m\cdot y(u)$ to series expansion for $m=0..1$

  $u^m\cdot y(u)=\sum_{k=0}^{\infty}a_k u^{k+r+m}$

- ◦ Shift index using $k->k-m$

  $u^m\cdot y(u)=\sum_{k=m}^{\infty}a_{k-m}u^{k+r}$

- ◦ Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..2$

  $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,u^{k+r-1+m}$

- ◦ Shift index using $k->k+1-m$

  $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,u^{k+r}$

- ◦ Convert $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m=1..3$

  $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,u^{k+r-2+m}$

- ◦ Shift index using $k->k+2-m$

$$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\,u^{k+r}$$

Rewrite ODE with series expansions

$$81a_0r(1+r)\,u^{-1+r} + (81a_1(1+r)(2+r) - 9a_0(1+r)(1+6r))\,u^r + \left(\sum_{k=1}^{\infty}(81a_{k+1}(k+r+1)(k$$

- $a_0$cannot be 0 by assumption, giving the indicial equation
  $81r(1+r) = 0$
- Values of r that satisfy the indicial equation
  $r \in \{-1, 0\}$
- Each term must be 0
  $81a_1(1+r)(2+r) - 9a_0(1+r)(1+6r) = 0$
- Each term in the series must be 0, giving the recursion relation
  $81a_{k+1}(k+r+1)(k+2+r) - 54(k+r+1)\,a_k\left(k+r+\frac{1}{6}\right) + a_{k-1}(3k-1+3r)^2 = 0$
- Shift index using $k- >k+1$
  $81a_{k+2}(k+2+r)(k+3+r) - 54(k+2+r)\,a_{k+1}\left(k+\frac{7}{6}+r\right) + a_k(3k+3r+2)^2 = 0$
- Recursion relation that defines series solution to ODE
  $a_{k+2} = -\frac{9k^2a_k-54k^2a_{k+1}+18kra_k-108kra_{k+1}+9r^2a_k-54r^2a_{k+1}+12ka_k-171ka_{k+1}+12ra_k-171ra_{k+1}+4a_k-126a_{k+1}}{81(k+2+r)(k+3+r)}$
- Recursion relation for $r = -1$

Book : Collection of Kovacic problems
Section : section 1
Problem number : 160
Date solved : `Monday, January 27, 2025 at 06:01:34 PM`
CAS classification : `[[_2nd_order, _with_linear_symmetries]]`

Solve

$$x^2\left(-x^2+2\right) y''-x\left(3x^2+2\right) y'+\left(-x^2+2\right) y=0$$

Solved as second order ode using Kovacic algorithm

Time used: 0.168 (sec)

Writing the ode as

$$\left(-x^4+2x^2\right) y''+\left(-3x^3-2x\right) y'+\left(-x^2+2\right) y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= -x^4+2x^2 \\ B &= -3x^3-2x \\ C &= -x^2+2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{-1}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(-\frac{1}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 2.300: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$
